History

A History of Meeting Industry's Need For Power

Since 1952, Katolight generator sets have been helping customers meet their need for reliable power for a myriad of applications including communications, hospitals, government and agricultural confined livestock and greenhouse operations.

Katolight began its dependable power story by serving agribusinesses in the heart of the Midwest farm belt. Today, Katolight generator sets can be found in thousands of places around the world, such as the National Institute of Health in Washington, D.C., the Beijing Newspaper in China, Telesat-Satellite Communications in Macau, Bonneville Power Authority of Oregon and Washington. Katolight generator sets also power hospitals, factories, government and agricultural installations across the United States.

Katolight provides generator sets that meet the growing demands of many varied and diverse market segments. Katolight's technical knowledge in the field of power generation has led to the development of diesel and gaseous powered generator sets used around the world.

The widespread acceptance of Katolight equipment reflects the company's reputation for quality and reliability in design, manufacturing and service. Katolight places great value on the establishment of long-term relationships with its customers and distributors, which is evident in the company's superior level of technical support and our emphasis on customer service.

Katolight has a great deal of successful experience in projects involving the development of generator sets to meet critical specifications. Much of this equipment has been produced to strict government performance and construction specifications. Katolight can design, produce and test engine generator sets to demanding quality and performance requirements.

Katolight's product line uses liquid cooled diesel, natural gas and liquid petroleum gas engines in sets ranging in size from 15 kW to 2800 kW. Systems feature standard or special controls, as well as components and switchgear to meet specifications. Katolight generator sets are designed to satisfy utility or special purpose applications.

Katolight currently operates out of over 110,000 square feet of manufacturing and office space with more than 160 employees and a national and international distribution network. Katolight customers continue to benefit directly from over 50 years of experience and flexibility.

Contact Katolight's marketing department for a seven minute video about the company.

KATOLIGHT CORPORATION

Performance Assurance Certification

The Performance Assurance Certification provided by Katolight Corporation certifies that each model and every production unit will reliably produce its rated output with all accessories with the selected fuel.

Katolight Corporation's Performance Assurance Certification is the most complete and extensive testing in the engine generator industry. It has always been the standard test performance of Katolight Corporation.

The Standard Unit Will Include:

- Full load at rated PF and maximum load, to verify engine power, overload and maximum capability.
- KVA, kilowatts, amperes, voltage. Frequency and voltage transients at one half and rated load. Frequency at: no load, full rated load and maximum output.
- Regular range (adjust), phase sequence, phase voltage balance.
- Stator and exciter field resistance.
- Insulation test, generator field, exciter armature, exciter field, generator armature or stator.
- Dielectric test, generator field, exciter armature, exciter field, generator armature or stator.
- All safety shutdown and automatic controls.
- Lube oil pressure (if applicable), water temperature (if applicable), battery charger (if applicable).
- Jacket water heaters and/or lube oil starting aids.
- Accessories (annunciator panel, chargers, pumps, transfer switches) as supplied.

Standard test procedures are per MIL-STD-705 test methods. Katolight Corporation is capable of performing complete MIL-STD-705 testing for critical, precise power, government and military installations.

Application performance is certified by Katolight for every unit manufactured. Our company's philosophy and performance are regularly reviewed to ensure continuity of the program and conformance with national and other codes or regulations affecting generator systems such as:

- NFPA 99—Health Care Facilities
- NFPA 70—National Electrical Code
- NFPA 110—Emergency and Standby Power Systems
- State of Pennsylvania Department of Labor and Industry

MIL-STD-705 Methods

301.1b	Insulation Resistance Test
302.1a	High Potential Test
401.1a	Winding Resistance Test
410.1a	Open Circuit Saturation Curve Test
503.1b	Start and Stop Test
505.2a	Over Speed Protective Device Test
507.1c	Phase Sequence Test (Rotation)
508.1c	Phase Balance Test (Voltage)
510.1c	Rheostat Range Test
511.1c	Regulator Range Test
511.2b	Frequency Adjustment Range Test
513.2	Indicating Instrument Test (Electrical)
515.1a	Low Oil Pressure Protective Device Test
515.2a	Over Temperature Protective Device Test
516.1	Controls, Direction of Rotation
640.1c	Maximum Power Test

Warranty Claim Information and Procedures

A fully completed start-up sheet must be submitted within 30 days of the start-up date. Without a valid, completed start-up sheet the warranty period will begin on the invoice date. All start-ups are to be completed within 12 months of invoice date. If this is not done, recertification of the unit or engine as required by some engine manufactures may be necessary to gain warranty status.

All warranty claims must be completed and submitted on a Katolight Warranty claim form that has a serialized number preprinted on the form. The pre-printed claim number is an authorization number that is used for tracking purposes only; it is not an approval number for payment. Warranty claims can be requested by contacting Katolight's Warranty Department.

All warranty claim forms must be completed in detail stating the complaint, cause and correction of the problem. When appropriate, pictures should be sent that show the problem and solution so that Katolight can rectify future situations.

All warranty claims must be received within 60 days of warranty repair. Warranty claims will only be processed and paid from a completed Katolight Warranty Claim form. Any other type of document submitted by itself, such as an invoice, will not be processed and will be returned to the appropriate service center. Submitting an invoice with the completed warranty claim form is acceptable and encouraged. After 60 days from the date of repair, if a warranty claim is submitted, the warranty claim will be subject for denial unless extenuating circumstances are communicated to Katolight prior to the end of the initial 60 day time period.

When Katolight request additional information (verbally or in writing) to help process a warranty claim, the information must be provided within 60 days from the date of request or the claim is subject to denial.

Defective parts must be shipped with the completed claim form within the 60 day time frame described above. Returned parts must be clearly identified with the serialized number that is printed on the claim form. If you have question as to feasibility of returning parts, please contact our warranty department. The warranty will not be approved until Katolight's Warranty and/or Service Department evaluates all parts. If the parts are not returned within the 60 day time frame, the warranty claim will be subject for denial unless extenuating circumstances are communicated to Katolight prior to the end of the initial 60 day time period.

Rate Agreements: Warranty rates for Shop Labor, Site Labor, Travel Labor, and Mileage must be approved and on record with the factory prior to commencing any warranty work. Sub-contracted warranty work will be paid at actual cost not exceeding the Service Station Rate Agreement.

Rates noted on the claim form must not exceed the rate agreement with the factory. If the rates are overstated on the warranty claim form, they will be subject to adjustment and the claim will be processed to avoid delay. The factory must approve any rate changes. If Katolight adjusts the claim amount, a copy of the submitted warranty claim form will be sent with the credit invoice showing where the adjustments were made.

Warranty Settlements: An approved warranty claim settlement will be processed as a warranty credit invoice; the warranty credit invoice will be mailed to the Service Center to the address on file with Katolight.

Warranty Denial: All denials will be addressed in a letter explaining reason for denial and will be addressed to the Service Center Service Department.

Contesting a Denied Warranty: Warranty claim denial can be contested within 30 days from the date of the denial. A detailed letter stating the reason or reasons for contesting the denial must be sent to Katolight Warranty Department for review. This also applies to claims that have had rate adjustments.

Site Labor: Site labor will be limited to reasonable time required to trouble shoot a problem, perform the actual warranty repair, and test as directed by the factory. This shall not include any excess time due to facility restrictions, special training required at site, removal or reinstallation of equipment that is not part of the generator set as supplied by the factory, or delays that are created by a facility which are beyond Katolight's control. All site labor is subject to the rate agreement with Katolight Corp.

Travel Labor / Mileage: Travel time and mileage charges are limited to the lessor of: a) Maximum of 400 miles roundtrip or b) Roundtrip miles from the nearest authorized service center to the site or, c) Actual miles traveled. All travel labor and mileage rates are subject to the rate agreement with Katolight Corp.

Warranty Claim Package should contain the following:

a. Completed serialized Katolight Warranty Claim form.
b. Any supporting documents for the claim, for example: Work Orders / tickets, receipts / invoices for parts, and invoice (optional).
c. Photos (digital or standard snapshots), if appropriate.
d. Defective part(s) if applicable.
e. Package must be clearly marked with the serialized number that is printed on the warranty claim form.

KATOLIGHT CORPORATION
PTO DRIVEN ALTERNATOR
STANDBY LIMITED WARRANTY

"FIVE YEAR"

Your Katolight Product has been manufactured and inspected with care by experienced craftspeople. If you are the original consumer, Katolight Corporation warrants, for the period indicated below, each product to be free from defects in materials and workmanship. Repair, replacement or appropriate adjustment at Katolight Corporation's option will be furnished if the product, upon Katolight Corporation's inspection, is properly installed, maintained and operated in accordance with Katolight Corporation instruction manuals. This warranty does not apply to malfunctions caused by damage, unreasonable use, misuse, repair or service by unauthorized persons, or normal wear and tear.

KATOLIGHT PRODUCT PERIOD OF WARRANTY: PTO Driven Alternator complete with Gear Box: Five (5) years parts, site and / or shop labor for the first two (2) years from date of purchase. Accessories: One (1) year parts and site or shop labor form date of purchase.

For a description of accessories and exclusions from this limited warranty, review the listings on the reverse side of this document.

TO OBTAIN WARRANTY SERVICE: Contact your nearest Katolight Service Representative by calling or writing Katolight Corporation. Attention: Service Department. (See address and telephone below.)

Katolight shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall Katolight be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING BUT NOT LIMITED TO A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

State laws regarding rights of consumers may vary from state to state.

KATOLIGHT CORPORATION
100 Power Drive / PO Box 3229
Mankato, MN 56002-3229
Phone: (507) 625-7973 / Fax: (507) 625-2247 www.Katolight.com

1. The following items are among those that are not considered nor will they be covered under the existing warranty program.
   a. Normal maintenance costs.
   b. Non-Katolight replacement part(s) will void the entire limited warranty.
   c. Products that are modified in any form without the written consent of Katolight will void the entire limited warranty.
   d. Shipping damage of any type. All equipment is shipped F.O.B. factory and is consigned to the carrier once loaded for shipment. It is the responsibility of the receiver to sign and note any damage to the equipment and a freight damage claim filed by the receiver.
   e. Any installation errors or damage of the equipment when shipped as ordered.
   f. Any overtime labor to make repairs under warranty.
   g. Any special access fees required to gain access to Katolight equipment not limited to but including any training or safety policy requirements to gain access.
   h. Additional costs associated with inaccessible installations, including removal and reinstallation of the generator.
   i. Rental equipment used during warranty work such as generators, rigging equipment such as a crane or boom truck, tractors, load banks and special testing above factory requirements, etc.
   j. Misuse or abuse including installation and thereafter.
   k. Normal wear and tear, maintenance and consumable items that are not required as part of a warranty repair. Consumable items include but are not limited to gear lube and fuses.
   l. Acts of nature such as lightning, wind, flood, or earthquake.
   m. Any damage due to situations beyond the control of the manufacturing of the product or workmanship of the product.
   n. Installation or operation outside the guidelines as stated in the Installation Guide and Owners Manual.
   o. Misapplication of the equipment such as usage outside the original design parameters as stated on the nameplate of the equipment.
   p. Shaft or spline damage caused by improper shaft alignment.
   q. Damage from improper storage when not in use.
   r. Any repair labor time that is determined to be excessive, e.g., two or more people performing a one-person job.
   s. Any expenses associated with investigating performance complaints in which no defect is found.
   t. Any associated costs for replacing components that are found not to be defective.

2. The aforementioned is a representation of things not covered by the standard "**LIMITED WARRANTY".** If there are questions as to warranty coverage it is advisable to contact the factory in advance of filing a claim.

3. The accessories that are limited to one (1) year parts and labor include but are not limited to:
   a. Tap changing switches
   b. Circuit Breakers
   c. Cords and receptacles.
   d. Trailer
   e. PTO Shaft
   f. Manual Transfer Switches

KATOLIGHT CORPORATION
STANDBY LIMITED WARRANTY

"TWO YEAR 1500 HOURS"

Your Katolight Product has been manufactured and inspected with care by experienced craftspeople. If you are the original consumer, Katolight Corporation warrants, for the period indicated below, each product to be free from defects in materials and workmanship. Repair, replacement or appropriate adjustment at Katolight Corporation's option will be furnished if the product, upon Katolight Corporation's inspection, is properly installed, maintained and operated in accordance with Katolight Corporation instruction manuals. This warranty does not apply to malfunctions caused by damage, unreasonable use, misuse, repair or service by unauthorized persons, or normal wear and tear.

KATOLIGHT PRODUCT PERIOD OF WARRANTY: Engine Generator Set: Parts and Labor for two (2) years or 1500 hours from the date of invoice by factory. Accessories: Parts and labor for one (1) year from date of invoice from factory. Transfer switches: If purchased with a generator set: Parts and labor for two (2) years from date of invoice by factory. The warranty period can be adjusted to the date of start up if completed within twelve (12) months of invoice date. A valid warranty requires that: (1) the Katolight start-up validation form must be completed, returned with in 30 days of start-up date and on file at Katolight Corporation. (2) the engine registration form must be completed and returned to manufacturer as stated in the instructions with registration form. And (3) all supporting maintenance records must be kept on file with the end user and made available upon request from factory. The generator set must be routinely exercised in accordance with operating instructions. Engine generator sets that are stored longer than six (6) months (180 days) from date of shipment are subjected to special requirements. Contact Katolight's Factory Service Center for instructions

For a description of accessories and exclusions from this limited warranty, review the listings on the reverse side of this document.

TO OBTAIN WARRANTY SERVICE: Contact your nearest Katolight Service Representative. For assistance in locating your nearest authorized service representative, contact Katolight Corporation, Attention: Service Department. (See contact information below.)
Warranty service may only be performed by Katolight authorized service providers. Service performed by unauthorized persons will void all warranties.

Katolight shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall Katolight be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING BUT NOT LIMITED TO A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

State laws regarding rights of consumers may vary from state to state.

KATOLIGHT CORPORATION
100 Power Drive / PO Box 3229
Mankato, MN 56002-3229
Phone: (507) 625-7973 / Fax: (507) 625-2247 www.Katolight.com

1. The following items are among those that are not considered nor will they be covered under the existing warranty program.
   a. Battery or Batteries of any type or kind. The Battery Manufacturer warranty applies to these only. Any warranty for such, should be handled with the manufacturer's local distributor according to their policies.
   b. Adjustments to fuel systems or governor system at time of start up or any time after. This is acceptable only when a defective part has been replaced, returned to the factory and approved as defective.
   c. Normal maintenance costs: adjustments, loose/leaking fittings or clamps, and tune-ups performed during start up or anytime thereafter.
   d. Due to shipping, manufacture is not responsible for loose connections. All connections must be checked at time of start-up.
   e. Non-Katolight replacement part(s) will void the entire limited warranty.
   f. Products that are modified in any form without the written consent of Katolight will void the entire limited warranty.
   g. Shipping damage of any type. All equipment is shipped F.O.B. factory and is consigned to the carrier once loaded for shipment. It is the responsibility of the receiver to sign and note any damage to the equipment and a freight damage claim filed by the receiver.
   h. Any installation errors or damage of the equipment when shipped as ordered.
   i. Any overtime travel or labor to make repairs under warranty.
   j. Any special access fees required to gain access to Katolight equipment not limited to but including any training or safety policy requirements to gain access.
   k. Additional costs associated with inaccessible installations, including removal and reinstallation of the generator set.
   l. Rental equipment used during warranty work such as Generators, rigging equipment such as a crane or boom truck, load banks and special testing above factory requirements, etc.
   m. Excess mileage charges. Any authorized service provider may perform warranty service anywhere, but will only be paid travel from the nearest service center and limited to 400 miles round trip.
   n. Any equipment not factory approved and engineered for use on Katolight products. This includes but is not limited to after market items such as special fuel systems, enclosures, exhaust systems, or switch gear that had been sought out and quoted by a third party to be included in billing of the Katolight equipment.
   o. Misuse or abuse including installation and thereafter.
   p. Normal wear and tear, maintenance and consumable items that are not required as part of a warranty repair. Consumable items include but are not limited to belts, hoses, coolant, oil, filters, and fuses.
   q. Acts of nature such as lightning, wind, flood, or earthquake.
   r. Any damage due to situations beyond the control of the manufacturing of the product or workmanship of the product.
   s. Installation or operation outside the guidelines as stated in the Installation Guide and Owners Manual.
   t. Diesel engine "Wet Stacking" due to lightly loaded diesel engines.
   u. Misapplication of the equipment such as usage outside the original design parameters as stated on the nameplate of the equipment.
   v. Travel expense on portable equipment.
   w. Trailer lights, wiring and brakes.
   x. More than one trip to job-site because Service Vehicle was not stocked with normal service parts.
   y. Lodging expense of person(s) performing service unless approved in advance by factory.
   z. Engine fluids.
   aa. Units purchased at the Standby Power rating that are being used in a prime power application.
   bb. Any repair labor time that is determined to be excessive, e.g., two or more people performing a one-person job.
   cc. Any expenses associated with investigating performance complaints in which no defect is found.
   dd. Any associated costs for replacing components that are found not to be defective.
   ee. Any adjustments covered in the start-up and inspection forms that are to be completed during start-up.

2. The aforementioned is a representation of things not covered by the **"LIMITED WARRANTY"**. If there are questions as to warranty coverage it is advisable to contact the factory in advance of filing a claim.

3. The accessories that are limited to one (1) year parts and labor include but are not limited to:
   a. Battery Chargers
   b. Water Heaters
   c. Load Banks
   d. Tap changing switches
   e. Circuit breakers
   f. Day tank pumps and controls
   g. Hand priming pumps
   h. Oil leveler systems
   i. Strip heaters
   j. Gas solenoid valves
   k. Gas flex pipes
   l. Cords, receptacles and cord reels
   m. Housing lights, space heaters and associated equipment.

KATOLIGHT CORPORATION
STANDBY LIMITED WARRANTY

"FIVE YEAR 1500 HOURS"

Your Katolight Product has been manufactured and inspected with care by experienced craftspeople. If you are the original consumer, Katolight Corporation warrants, for the period indicated below, each product to be free from defects in materials and workmanship. Repair, replacement or appropriate adjustment at Katolight Corporation's option will be furnished if the product, upon Katolight Corporation's inspection, is properly installed, maintained and operated in accordance with Katolight Corporation instruction manuals. This warranty does not apply to malfunctions caused by damage, unreasonable use, misuse, repair or service by unauthorized persons, or normal wear and tear.

KATOLIGHT PRODUCT PERIOD OF WARRANTY: Engine Generator Set: Parts for five (5) years including labor for the first two (2) years or 1500 hours from the date of invoice by factory. Accessories: Parts and labor for one (1) year from date of invoice from factory. Transfer switches: If purchased with a generator set: Parts and labor for two (2) years from date of invoice by factory. The warranty period can be adjusted to the date of start up if completed within twelve (12) months of invoice date. A valid warranty requires that: (1) the Katolight start-up validation form must be completed, returned with in 30 days of start-up date and on file at Katolight Corporation. (2) the engine registration form must be completed and returned to manufacturer as stated in the instructions with registration form. And (3) all supporting maintenance records must be kept on file with the end user and made available upon request from factory. The generator set must be routinely exercised in accordance with operating instructions. Engine generator sets that are stored longer than six (6) months (180 days) from date of shipment are subjected to special requirements. Contact Katolight's Factory Service Center for instructions

For a description of accessories and exclusions from this limited warranty, review the listings on the reverse side of this document.

TO OBTAIN WARRANTY SERVICE: Contact your nearest Katolight Service Representative. For assistance in locating your nearest authorized service representative, contact Katolight Corporation, Attention: Service Department. (See contact information below.)
Warranty service may only be performed by Katolight authorized service providers. Service performed by unauthorized persons will void all warranties.

Katolight shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall Katolight be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING BUT NOT LIMITED TO A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

State laws regarding rights of consumers may vary from state to state.

Katolight Power Systems Solutions

Gen-Set Start Up Procedures

Note: Installation should be complete with site load connected. Load should be available when start-up is performed to allow final adjustment and prove entire system.

1. Starting with the Katolight Warranty Validation Sheet

    a. Fill out the top portion completely with the gen-set information.

2. Pre-start checks to be made

    a. Check physical appearance and note any damages or problems. (If severe could cause operation problems, consult the factory before proceeding.)

    b. Check and/or fill lube oil level per engine manufacturer's recommendations (and note). Also, check all hoses and clamps for tightness.

    c. Check and/or fill engine coolant per engine manufacturer's recommendations (and note). Also, check all hoses and clamps for tightness.

    d. Inspect fuel connections and bleed system as required.

    e. Inspect exhaust system for proper and complete installation per Katolight Installation Guide's recommendations. Make sure there are no restrictions. (Consult the factory on any questions.)

    f. Inspect all electrical connections for completion, quality, and safety per installation guide. In the case where items are not met, abort start-up until completed or corrected satisfactorily. (Consult the factory with questions.)

    g. Inspect cooling ducts if applicable. Check for quality installation, completion, and adequate sizing per installation guidelines.

    h. Inspect unit mounts for completion.

        1. Rubber pad type mounts should be installed between unit base and concrete or sub-base tank. The anchor bolts should be double nutted and not tightened to base to allow for slight movement. (See installation guide.) **Note:** Gen-set should never be mounted tightly to concrete due to inconsistencies in the surface that could cause twisting in the drive alignment and result in damage.

        2. Spring type mounts must be installed per Katolight Installation Guide.

    i. Inspect and/or make battery connections with respect to polarity and voltage. Incorrect installation can damage equipment.

j. Inspect transfer switch installation. Be sure the ATS is free from all foreign materials (filings, metal particles and tools, etc.,). Check all connections. Manually transfer before energizing. See installation guide and ATS manual.

3. Now that all the above checks are made and complete, the gen-set can be started in the manual position. (**Note:** do not transfer load at this time.) With gen-set running, check engine gauges and unit meters (oil pressure, water temperature, battery ammeter, AC voltage, and AC frequency) to see that the unit is operating accordingly. Also at this time check phase rotation of both normal and emergency sources and check voltage of both sources for proper match. (Always perform these checks at the ATS if possible.) If phase rotation is reversed, stop gen-set and correct. If voltage is incorrect readjust. When correct, stop gen-set. Put gen-set switch in auto position. (Unit should not start.)

   To Test system, shutting off utility power is recommended but not always possible. In this case follow the ATS test procedures to put the system on line. Make recordings of load test on warranty validation sheet. Include all meter readings. Watch for proper operation, leaks, etc., and make notes of such. When normal power is restored the ATS will timeout, re-transfer to normal, then, in most cases allow for engine cool down before stopping automatically. (Timing functions may vary.)

4. Final mechanical checks and visual inspection

   a. Check for oil leaks, note and/or repair as necessary.

   b. Check for coolant leaks, note and/or repair as necessary.

   c. Check exhaust for tightness and leaks, make necessary repairs.

   d. Check heater(s) and battery charger.

   e. Check belts for proper tension.

5. Safety Switch Checks

   a. Start unit in manual position and perform static test on LOP, HWT, by switching terminal to ground until shutdown occurs. May take up to 20 seconds on LOP.

   b. Now restart unit again to test overspeed safety. Run engine speed slowly until shutdown occurs. Use speed adjust pot on electronic governors. **Note:** Do not pull throttle open fast. This could cause damage to unit. Speed must be raised slowly.

   c. Overcrank test: With unit in the off position, disconnect start solenoid wire #3 on KASSEC engine controls. Then put switch in manual position. This will initiate start. After the programmed time, the overcrank light will come on. Times are as follows: One shot time – 45 seconds; Cycle crank time – 10 seconds crank, 10 seconds rest, total of 5 cycles. Reconnect wire and start unit to be sure unit is again fully operational. Stop unit. Put unit switch in automatic. System is ready to go.

6. Special Testing – Load Bank Run (If required)

   a. After pre-start checks are completed, (Sections 1 and 2a through 2j), load bank(s) can be connected, preferably at the mainline breaker on gen-set. Be sure to check specs for length of load run and type of test required by customer.

KATOLIGHT® CORPORATION

START-UP REQUEST FORM

To provide an authorized factory start-up at the lowest possible prices, we must request that the following checklist and tasks be completed prior to a Katolight representative's arrival at the installation site to perform the start-up.

(Please Print)
Unit Serial Number: _____ Contact Name: _____

Company Name: _____ Title: _____

Please attach a map or directions to the site. **Phone Number: _____**

- ☐ Unit set in place on vibration pads with floor anchor/studs to prevent movement.
- ☐ Radiator ducted to properly sized air discharge louvers.
- ☐ Unit full of oil and water/anti-freeze mix.
- ☐ Battery filled with acid and fully charged.
- ☐ Battery charger mounted with AC and DC wired, if not supplied mounted by the factory.
- ☐ All AC and DC electrical connections made.
- ☐ Engine heater wired to normal AC power supply.
- ☐ Fuel inlet and return lines run between the unit and fuel storage system, system filled and primed to the engine with proper fuel.
- ☐ Exhaust system in place and supported so that the exhaust manifold does not carry weight of exhaust system.
- ☐ Air inlet louver motor wired to an emergency generator source point to open upon the start of an engine generator set.
- ☐ Generator room cleaned of construction debris including excess nails, bolts, nuts, panel knockouts, etc. It is very important that the radiator fan area is checked for debris, as damage to the equipment and personal injury can occur if loose items come in contact with the fan when the unit is initially started.

Consult your Katolight Installation Guide on any questions.

If, upon arrival at the installation site, our representative cannot perform the start-up as a result of defective Katolight equipment, the problems will be resolved and we will reschedule another start-up date at the earliest possible date at no additional charge.

If the start-up cannot be performed due to an incomplete installation or for reasons beyond Katolight's control, you may incur an additional start-up charge at a later date.

Serial Number: _____

How to Read Katolight Model Numbers

Katolight's model numbering format is composed of six sections:

1. Prefix
2. First number group
3. First letter
4. Second letter
5. Third letter
6. Last number

Forward

This Installation Guide provides general instructions for installing your Katolight generator set properly. It is essential that every person who works on or with the generator set be completely familiar with the contents of this manual, and that he/she carefully follows the instructions contained herein.

Each installation may require some modification of the suggested guidelines in this manual. Installations must be consistent with locally applicable standards and take into consideration safety guidelines and measures.

Following this guide will result in an efficient and reliable installation. Carefully follow all procedures and safety precautions to ensure proper equipment operation and to avoid bodily injury. Read and follow the Safety Precautions section at the beginning of this manual.

IMPORTANT

Information in this publication represents data available at the time of print. Katolight reserves the right to change this publication and the products represented without notice and without any obligation or liability whatsoever.

All instructions and diagrams have been checked for accuracy and simplicity of application. However, the skills of the installer are most important. Katolight does not guarantee the result of any installation contained in this manual. Nor can Katolight assume responsibility for any injury or damage to property. Persons engaging in installation do so entirely at their own risk.

Safety Precautions

IMPORTANT SAFETY INSTRUCTIONS

Electromechanical equipment, including generator sets, transfer switches, switchgear, and accessories, can cause bodily harm and pose life-threatening danger when improperly installed, operated, or maintained.

Dangers, Warnings and Cautions are used in this manual to alert the operator to special instructions concerning a particular procedure that may be hazardous if performed incorrectly. These safety alerts alone can not eliminate the hazards that they signal. Strict compliance to these special instructions and common sense operation are major accident prevention measures. Observe all warnings found on the equipment. Ensure that warning labels are legible and not obstructed by dirt, grease or other equipment. Katolight Corporation can not anticipate every possible circumstance that might involve a hazard. The warnings in this manual and on tags and decals affixed to equipment are, therefore, not all inclusive.

DANGER

Danger indicates the presence of a hazard that will cause severe personal injury, death, or substantial property damage.

WARNING

Warning indicates the presence of a hazard that can cause severe personal injury, death, or substantial property damage.

CAUTION

Caution indicates the presence of a hazard that will or can cause minor personal injury or property damage.

This symbol signifies high voltage.

The following safety rules should be strictly complied with:

ACCIDENTAL STARTING

Be aware that the generator set could start at any time in the "AUTO" mode. Keep clear of all moving parts and be sure to turn switch to the "OFF" position before servicing and disconnect the negative battery cable after disconnecting the battery charger circuit.

BATTERY

For proper unit operation, battery minus (-) terminal must always be connected to ground. Reverse connection of the battery will severely damage or destroy the battery charging alternator, regulator and other polarity sensitive devices.

Wear protective safety eyeglasses and gloves when handling starting batteries and electrolyte. Battery acid can cause serious burns if it contacts eyes or skin.

Servicing of batteries is to be performed or supervised by personnel knowledgeable of batteries and the required precautions. Keep unauthorized personnel away from batteries.

Do not smoke or use an open flame when servicing batteries. Batteries generate an explosive gas during charging.

The replacement starting battery or batteries must be of equal size and cold cranking amps.

The generator controls must be in the off position when replacing the batteries.

Do not dispose of battery or batteries in a fire. The battery is capable of exploding.

Do not open or mutilate the battery. Released electrolyte has been known to be harmful to the skin and eyes and to be toxic.

A battery presents a risk of electrical shock and high short circuit current. The following precautions are to be observed when working on batteries:

1. Remove watches, rings, or other metal objects
2. Use tools with insulated handles

VENTED BATTERIES

The installation of the engine generator shall provide enough ventilation to ensure that gases generated by vented batteries during charging or caused by equipment malfunction are removed.

The electrolyte is a dilute sulfuric acid that is harmful to the skin and eyes. It is electrically conductive and corrosive. The following procedures are to be observed:

1. Wear full eye protection and protective clothing
2. Where electrolyte contacts the skin, wash it off immediately with water

3. Where electrolyte contacts the eyes, flush thoroughly and immediately with water
4. Spilled electrolyte is to be washed down with an acid-neutralizing agent. A common practice is to use a solution of one pound (500 grams) bicarbonate of soda solution to be added until the evidence of reaction (foaming) has ceased. The resulting liquid is to be flushed with water and the area dried.

Lead acid batteries present a risk of fire because they generate hydrogen gas. The following procedures are to be followed:

1. DO NOT SMOKE when near batteries
2. DO NOT cause flame or spark in battery area
3. Discharge static electricity from body before touching batteries by first touching a grounded metal surface

FIRE HAZARD

Keep fire extinguishers in accessible locations. Use appropriate fire extinguishers as recommended by NFPA.

Remove all unnecessary grease and oil from the unit. Accumulated grease and oil can cause overheating and engine damage, which present a potential fire hazard.

When an open bottom base is used, the stationary engine generator assembly is to be installed over noncombustible materials. It should be located such that it prevents combustible materials or loose debris from accumulating under or inside the generator set.

Do not service the engine when any ignition source such as an open flame is present. “DANGER” signs must be placed to warn of the fire hazard. No work may be performed on the engine involving an ignition source such as open flames, cutting, welding, or grinding.

A fire extinguisher (dry chemical or carbon dioxide, CO2) must be immediately available to the mechanics while working. When liquefied or natural gas leaks or escapes, it can result in dangerous accumulations of gas, which might cause a serious flash or explosion. Careful ventilation of the area is mandatory in the event of a fuel leak.

EXHAUST SYSTEM

Engine exhaust gases contain DEADLY carbon monoxide gas, which is colorless and odorless. If breathed in sufficient concentrations, this gas can cause severe nausea, fainting, or death. Provide adequate ventilation to prevent buildup of exhaust gases. When the generator is installed inside a room or enclosure, exhaust gases must be piped outdoors. Install the exhaust system so exhaust gas does not leak at joints or piping connections. Make certain that the extended exhaust piping is plumbed properly and that the exhaust is not near an intake ventilator.

Increase the exhaust pipe diameter as necessary to reduce back pressure. Use a minimum number of fittings and elbows to prevent back pressure in the engine exhaust system. Be sure the enclosure has proper ventilation to accommodate the engine cooling system.

FUEL SYSTEM

Gaseous, Natural Gas and Liquid Propane Gas are extremely flammable and vapors are EXPLOSIVE. Comply with all laws regulating the storage and handling of these fuels. Check for leaks frequently and correct such leakage immediately.

Do not fill fuel tanks while the engine is running.

Do not smoke or use open flame at any time when fuel is being handled. Fuel vapors are both toxic and flammable.

Liquid petroleum gas (LPG) systems operate at tank pressures around 100 psi or above. The tank pressures are regulated down. Vaporized LPG systems operate at pressures near 6 oz., as do most natural gas systems.

Safety precautions when handling liquefied petroleum gas cannot be over-emphasized. There are state, county and city codes, and fire regulations covering the handling and storage of liquefied petroleum gas or natural gas. In addition to the safety suggestions in this manual, all local codes and fire regulations on this subject must be followed explicitly. Where local codes are more stringent than the suggestions in this manual, the local codes must be given priority.

Before proceeding with any service, be certain that all switches are in the OFF position, disconnect battery ground cable, remove fuses in DC systems and turn off the battery charger. These safety suggestions apply to service of any engine using liquefied petroleum gas or natural gas fuel regardless of the work to be performed. When servicing the engine, ensure that there is adequate ventilation. This is to avoid the accumulation of gas/air mixtures in and about the engine caused by undetected leaks.

Any service performed on the fuel system requires that:

- All threaded connections are sealed with proper pipe thread compound. Replace defective fittings and reseal all connections.
- Fuel system is checked for leaks. Leaks are not permissible. Odorants, which are strong smelling components (an odor similar to spoiled cabbage), are added to liquefied petroleum gas as a warning agent to indicate the leakage of even small quantities of gas.

- A soap solution applied with a soft brush will bubble to indicate leaks. Never use an open flame to check for leaks. All leaks must be sealed.
- All flexible fuel connections are checked, metallic and neoprene, with the soap solution.

It is important to remember that all gas fuel systems are pressurized. Be certain that the fuel valves are tightly closed and all fuel has been vented before starting any repair work on the fuel system.

HAZARDOUS NOISE

Prolonged unprotected exposure to hazardous noise levels may cause loss of hearing. Never operate the generator set without a muffler or with a faulty exhaust system. Ear protection may be required.

HAZARDOUS VOLTAGE/ELECTRICAL SHOCK

Dangerous voltages are present at power terminals of this equipment. Contact with such terminals will result in extremely dangerous and possibly lethal electric shock. Never allow any unqualified person to install, operate or service the equipment. The standby electric system must be installed, tested, and inspected per the manufacturer's recommendations. All codes, standards, regulations, and laws pertaining to the installation must be strictly complied with.

Accidental contact with electrical equipment can cause severe injury and death if the equipment is not properly grounded. The frame and external electrically conductive parts of this equipment must be properly connected to an approved earth ground, in accordance with applicable electrical codes. A grounding lug is provided on the generator and in other equipment for this purpose.

CAUTION: RISK OF ELECTRIC SHOCK!

The grounded conductor must be bonded to ground in accordance with the National Electrical Code, NFPA 70. The unit shall not be used in floating output applications.

Remove all electrical power before removing protective shields for service or maintenance. Exercise extreme caution when working on or around electrical components. Open or poorly insulated conductors are extremely dangerous during operation. Severe, possibly fatal, shock may result. Make certain that all conductors are properly insulated or guarded, all grounds are made and that the area is dry. Do not tamper with interlocks.

In the event of an accident from electrical shock, shut down the generator set immediately. If the set cannot be shut down, free the victim from contact with a dry nonconductor, avoiding direct contact with victim until free of the

conductor. If the victim is unconscious, apply artificial respiration if qualified and get medical help immediately.

Verify that all power leads and control connections are properly insulated before starting the generator set. Neglecting this may result in extensive damage to equipment and personal injury. This problem arises if the unit is started before electrical installation is completed.

Make certain the area is well ventilated to dissipate any flammable vapors, which may collect from fuels. When servicing any part of the electrical system or making any connections, be sure the main switch is OFF and disconnect battery ground cable or remove fuse in DC system. Turn off the battery charger. Clean or service the generator set only when the engine is shut down. If the unit stops because of an engine safety device, do not attempt to restart until the cause for shutdown has been corrected.

HOT PARTS

The exhaust manifold, turbocharger(s), and extended exhaust piping are HOT when the engine is running. These can remain hot for long periods of time after the engine shuts off. Avoid contact with these parts. Consider insulating the exhaust system if installation is such that unintentional contact with the exhaust system components is likely.

Coolants under pressure have a higher boiling point than water. DO NOT open a radiator or heat exchanger pressure cap while the engine is running. Allow the generator set to cool and bleed the system pressure first.

MOVING PARTS

Moving parts can cause severe personal injury or death. Do not wear loose clothing or jewelry in the vicinity of moving parts, or while working on electrical equipment. Loose clothing and jewelry can become caught in moving parts. Jewelry can short out electrical contacts and cause shock or burning.

HANDLING

Do not use lifting devices with marginal capacities when lifting or moving the unit. Observe the center of gravity of the equipment to be lifted and do not allow the generator set to swing if suspended. Make certain the supporting structure is adequate to support the unit. Failure to observe this warning may result in equipment damage and serious or fatal injury.

1 General

When installed properly and according to applicable codes, your Katolight generator set will perform safely and reliably. Incorrect installation can cause continuing problems. Figure 1-1 illustrates a typical installation. Your authorized generator set distributor/dealer can provide advice about or assistance with your installation.

This manual references organizations and their codes that govern generator set selection and installation for US installations. Installers must comply with national and local codes when applicable.

NFPA 37……..Stationary Engines and Gas Turbines
NFPA 54……..National Fuel Gas Code
NFPA 70……..National Electric Code®
NFPA 99……..Standard for Health Care Facilities
NFPA 101……Life Safety Code
NFPA 110……Emergency Standby Power Systems
UL-2200……...Stationary Engine Generator Assemblies

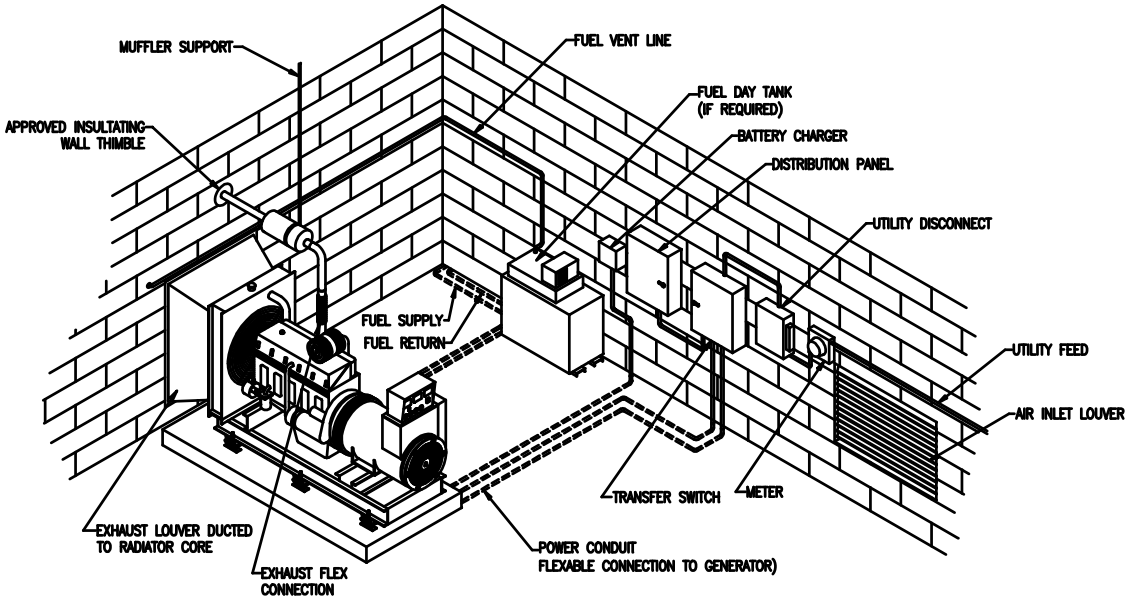

Figure 1-1: Typical generator set installation

2 Lifting Provisions

To ensure personal safety and prevent damage to the product, we strongly recommend the guidelines in Figure 2-1 be observed when lifting Katolight generator sets. Due to the different designs, dimensions and weights of the generator sets, specific instructions for each model are not provided. It is the responsibility of the dealer/distributor to see that generator set lifting is performed within the framework of these guidelines.

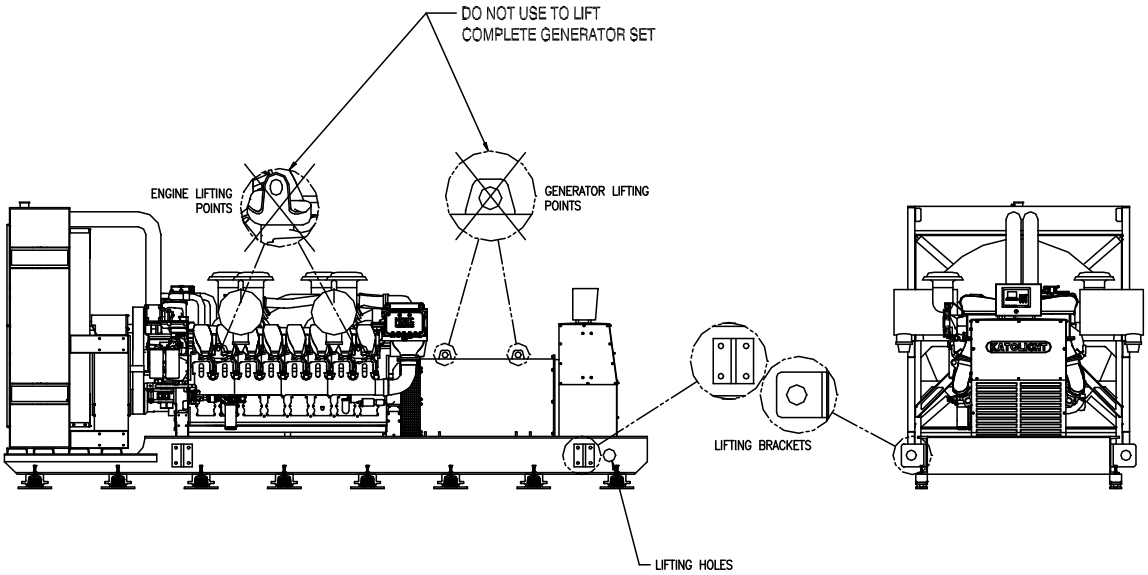

Figure 2-1: Lifting provisions

3 Location

The location of the generator set is influenced by factors such as ventilation, exhaust piping, electrical service, fuel supply and accessibility for maintenance and service.

Before selecting the location for your generator set, consider the following:

- Supporting structure must be adequate for the generator set and accessories. For information on mounting on an inertia pad, see Section 4. For any other set-up, consult a structural engineer for an appropriate design.
- Area should be clean, dry and not subject to flooding
- Ventilation should be available in the area with a minimum amount of duct work
- Exhaust gas must be piped away from the structure and any ventilation intakes. Piping must incorporate large radius, low restriction elbows.
- An adequate supply of fuel should be available at all times to sustain operation
- The main diesel fuel supply should be as close as possible to the unit. If the main fuel tank is installed underground, an auxiliary pump and day tank are necessary to transfer fuel from the main tank to the day tank.
- Vibration should be effectively isolated and dampened to reduce transmission of vibration and prevent fatigue fractures of connected systems.
- Area should provide easy access for maintenance and repair. A minimum clearance of three feet between an installed generator set and adjacent walls or other electrical equipment should be maintained on three sides of the generator set. Clearance of five feet should be maintained at the rear of the generator set to facilitate removal, should it become necessary.
- Applicable fire rating codes and standards must be met
- When an open bottom base is used, the stationary engine generator assembly is to be installed over noncombustible materials. It should be located such that it prevents combustible materials or loose debris from accumulating under or inside the generator set.

Local weather conditions will have a direct influence on location of the unit and the type of accessory equipment required to assure reliable operation. Extreme ambient temperature variations should be avoided. For ambient temperatures below 60 degrees, starting aids such as jacket water heaters and lubricating oil heaters will ensure dependable starting. Anti-condensation or

strip heaters are available for control panels and generators to maintain a temperature above the dew point to prevent condensation of moisture.

Standard Katolight transfer switches located indoors in heated facilities are enclosed in NEMA 1 enclosures. Various other NEMA enclosures may be needed. If the generator set is located outside, heaters are needed below 32 degrees Fahrenheit.

Consider preventive maintenance issues when selecting a generator set location. See Section 9 for a list of service points that should be accessible.

4 Mounting

Your Katolight generator set should be installed in a location that is able to support the weight of the unit and accessories, resist dynamic loading, and does not transmit generator noise and vibration. See Section 3 for detailed information on selecting a location for your generator set.

WEIGHT

The weight of the generator set and accessories will determine the type and design of the support structure. Generator set weight can be found in the specification sheet for your particular model. Be sure that the weight of accessory items and fuel (if a sub-base tank is used) are added to the total requirements.

INERTIA PAD/BASE

Your generator set must be mounted on a substantial inertia pad or base. The composition of the inertia pad should follow standard practice for the required loading. Common specifications call for 2500 psi concrete reinforced with eight-gage wire mesh or number 6 reinforcing bars on 12-inch (30-cm) centers.

To determine the depth of the inertia pad, the following formula can be used:

BASE DEPTH =	Wu / d * w * l

Where Wu = engine-generator set weight in pounds
d = concrete density (usually 145 lbs per cubic foot)
w = foundation width in feet
l = foundation length in feet

The inertia pad should be a minimum of twelve inches wider and twelve inches longer than the unit base. The inertia pad may be constructed higher than the floor level by three to eight inches for ease of maintenance.

To reduce the amount of unit vibration transmitted, you must isolate your inertia pad from the foundation. One method for isolating the inertia pad from the foundation is to use eight to ten inches of wet gravel or sand as a bed in the inertia pad pit. For other methods, consult a qualified structural engineer.

To allow settlement of the inertia pad from the foundation, expansion joints should be incorporated between the inertia pad and the foundation.

VIBRATION ISOLATION

Vibration is a normal by-product of the operation of any generator set. Vibration transmitted to surrounding areas will increase the noise level and if severe, can cause structural damage. To minimize this risk, all generator sets should have vibration isolation between the generator base and inertia pad.

All fuel, coolant, exhaust and electrical connections must have flexible sections to isolate vibration. Leaks or fractures can develop rapidly without vibration isolation and there is a danger of eventual total failure.

For generator sets enclosed within a building, where maximum vibration isolation is required, spring mounts provide vibration isolation between the generator base and the structure. Check state and local codes for such requirements.

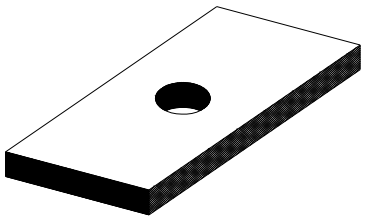

Figure 4-1: Typical pad type vibration

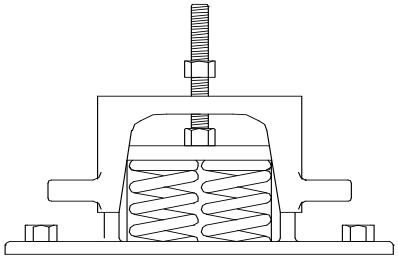

Figure 4-2: Spring mount vibration isolator

Anchor bolts should be loosened and double nutted after installation to avoid base distortion caused by unlevel inertia pads.

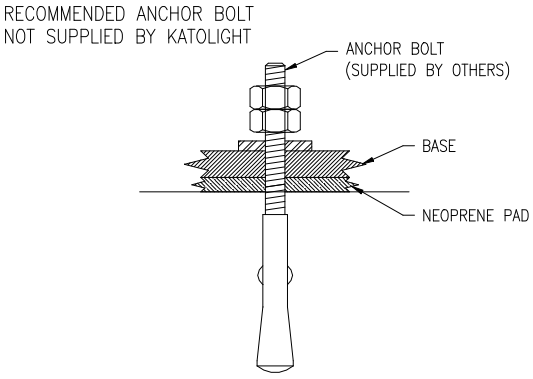

Figure 4-3: Recommended anchor bolt

5 Air Requirements

GENERAL

When installing engine generator sets, great care must be taken to insure adequate ventilation. Proper installations require enough ventilation to cool the engine generator set as well as supply adequate air for combustion.

When installing the ventilation system, the following factors should be considered:

- Location of intake and exhaust louvers
- Method of actuation of intake and exhaust louvers
- Ambient temperature
- Routing of exhaust air duct

The air intake and exhaust should be in line to provide engine room ventilation air flow which will parallel the generator set air flow over the engine, through the radiator and/or exhaust louver. The inlet and outlet openings must be large enough to provide the volume of air required by the engine generator.

NOTE

Exhaust louver effective opening should be at least 25% to 50% larger than engine radiator core. Intake louver should be 50% to 100% larger in effective opening than engine radiator core.

In most applications, intake and exhaust louvers should be used. Figure 5-1 indicates a typical louver.

Care should be taken to provide adequate open space outside the exhaust louver so as not to obstruct airflow.

Units with mounted radiators should be installed with ducting between the radiator and the exhaust louver to prevent recalculation of air.

CAUTION

Ensure that the exhaust ducting is installed so that no recirculation of radiator exhaust air occurs. Failure to prevent re-circulation could cause the unit to overheat and shut down.

The exhaust louver should not be exposed to high prevailing winds, since wind pressure may reduce fan discharge and reduce cooling. The duct should be constructed with as few bends as possible. All units can be

supplied with radiator duct flanges of the required size to meet the customer's application.

If bends are required, they should be in the form of gradual sweeps to allow airflow with minimum restriction. Increase duct size one-fourth to one-half to compensate for bends.

Motorized and gravity louvers may be used to prevent entry of cold air which may cause difficulty in engine starting. (Refer to Chapter 8 for recommendations for wiring motorized louvers). Louvers also reduce the entry of rain, snow and insects into the building.

A gravity-operated louver can be used for the exhaust air. When the set operates, outlet airflow will open the louver and it will close automatically by gravity when the unit is shut down.

Generating sets with automatic start require the use of motor operated intake louvers. Motor operated louvers are held closed by spring tension and are driven to the open position by a motor operating through a mechanical linkage.

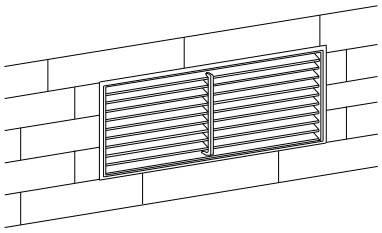

Figure 5-1: Typical center top pivoted louver

CAUTION

Care should be taken in wiring the system to ensure that the intake louver motor is supplied with power during all possible modes of unit operation, i.e. true power failure, simulated power failure due to incorporation of a system test switch, or automatic plant exercising. Incorrectly wired louver motors could result in the louvers closing prematurely during engine cool-down, resulting in overheating, engine shutdown, and possible damage to the unit.

In some extreme cold weather applications, the opening of intake louvers immediately upon starting may cause carburetor icing and vaporizing problems with engines utilizing gaseous fuels. Diesel engines may also be affected if lightly loaded. Thermostatically controlled louvers may be used to reduce the difficulties encountered with cold weather applications.

Figure 5-2 illustrates a typical generator set installation for units with unit-mounted radiators, indicating ducting and preferred locations of the louvers.

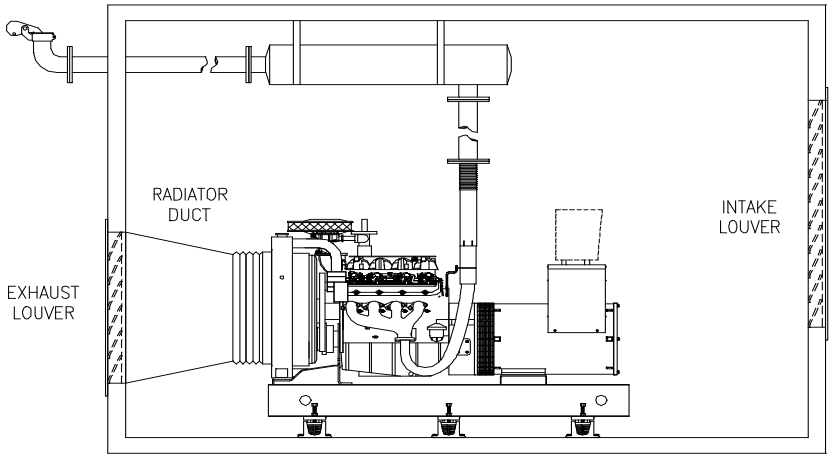

Figure 5-2: Typical installation with louvers

Engine-generator sets with remote cooling will not have an engine driven fan to move air through the generator room. As a result, a fan or some other means of moving air through the room must be considered. The fan must move the required amount of air against the allowable static friction.

The following formula may be used to estimate the amount of airflow required to remove engine and generator radiated heat and supply sufficient combustion air. The formula is based on air temperature of 100°F. Allowable room air temperature rise is 20° to 30° F.

$$V = \frac{Q}{0.018 * \Delta T}$$

Where V = Air flow through the engine-generator room (CFM)
Q = Engine-generator set radiated heat (BTU/min)
ΔT= Allowable room air temperature

Higher elevation installations will require increased airflow. Add 10% for each increase of 2500 feet. Also increase airflow for non-insulated exhaust silencer and other equipment that may add to the radiated heat in the room. Also keep in mind the required combustion airflow for the engine.

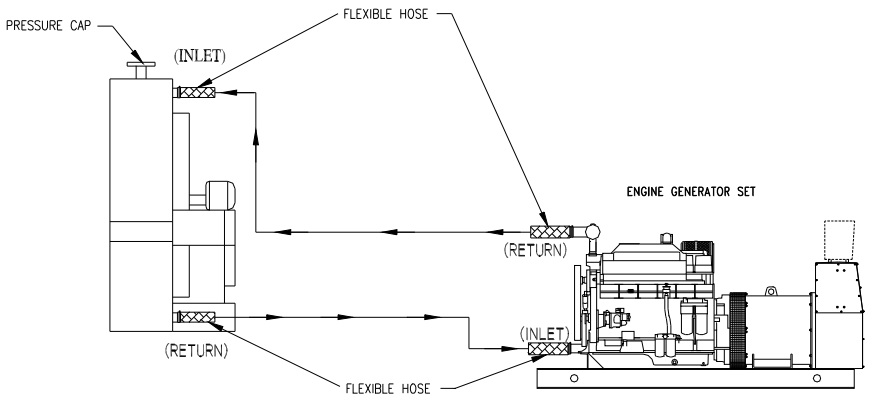

Figure 5-3: Typical remote radiator installation

6 Exhaust System

Proper exhaust system installation is essential for maximum generator set engine efficiency. Because exhaust fumes are deadly, great care must be taken when installing the exhaust system. Consideration must be given to back pressure, piping, and placement. Figures 6-1 and 6-2 show the general arrangement of recommended exhaust systems.

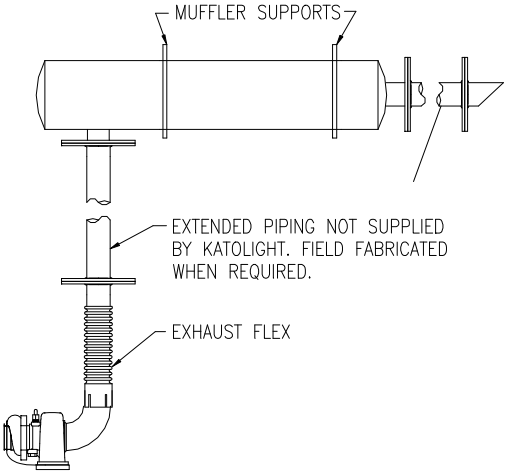

Figure 6-1: Typical side inlet exhaust

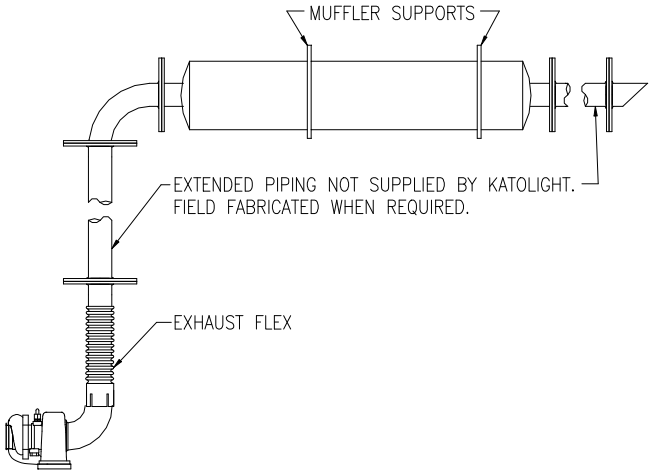

Figure 6-2: Typical end inlet exhaust

PLACEMENT

The exhaust pipe should terminate outdoors, away from doors, windows, or other building openings in an area where exhaust can dissipate. Placement of piping and exhaust silencer should take into account the location of combustible materials. If location cannot avoid these concerns, remove combustible materials on a regular basis. Keep dry grass, foliage, and combustible landscaping material a safe distance from the exhaust system.

WARNING

Inhalation of exhaust gases can cause death. Exhaust pipes must not terminate near fresh inlet vents of any type or near combustible materials. Avoid exhaust gas recirculation which could cause the engine-generator set to overheat. Generator sets installed outdoors inside enclosures should have their exhaust directed so that it will disperse away from buildings and building air intakes.

BACK PRESSURE

The installed exhaust system must not exceed the engine manufacturer's maximum exhaust back pressure limit. Damage may result from excessive back pressure. Causes may include:

- Insufficient exhaust pipe diameter
- Exhaust run too long
- Exhaust silencer too small or designed improperly
- Too many bends and/or constrictions in piping
- Obstruction in exhaust piping

Your Katolight generator set has been sized so that exhaust system back pressure is kept within the acceptable limits. However, in situations when extended piping or a flex connector other than the one supplied by Katolight must be used, contact Katolight to ensure that back pressure will not exceed the engine manufacturer's specification.

PIPING

Exhaust piping should conform to all applicable codes. Routing of exhaust piping should be as short and direct as possible. Exhaust piping should be of Schedule 40 black iron or steel having adequate strength and durability. The recommended material for exhaust piping is Schedule 40 black iron pipe. Where possible, sweep elbows with a radius of at least three times the pipe diameter should be used.

Exhaust pipes should be free standing, not supported by the engine or muffler. Where exhaust pipes attach to the engine, they must be connected with flexible connectors to minimize vibrations that can cause damage to the exhaust system.

CAUTION

Weight applied and vibration extended to the exhaust manifold or turbocharger could result in damage to these components. No exhaust piping weight may be carried by the engine, exhaust manifold or turbocharger.

FLEXIBLE SECTION

The Katolight supplied exhaust flex should be installed directly off the engine turbo elbow/manifold. This limits the stress on the engine exhaust manifold or turbocharger resulting from engine motion on its vibration mounts and temperature-induced changes in pipe dimensions. The flexible section should not be bent or used to make up for misalignment between the engine exhaust and the exhaust piping. Since typical exhaust temperatures range from 800~F (427~C) to over 1200~F (649~C) for some engines, seamless stainless steel should be used for the flexible section.

CAUTION

When installing a silencer, make certain flow direction is correct. Check inlet and outlet marking on the silencer nameplate.

EXTENDED PIPING

Engine exhaust piping can accumulate a considerable amount of condensed moisture after unit shutdown, particularly if the exhaust system is run through lengthy piping. To prevent condensed moisture from running back into the engine, exhaust piping should be sloped away from the engine and a condensate trap and drain should be incorporated at a low point ahead of engine manifolds. The trap should be drained periodically.

Horizontal extended exhaust pipe should terminate with a 45° tail pipe to prohibit rain from entering the system. A screen should be placed across the end of the tail pipe to keep birds and rodents from entering the system. Where vertical exhaust stack is necessary, a rain cap should be fitted to exclude rain and snow from the exhaust pipe.

Where there is a danger of extending piping coming in contact with combustible material or personnel, the piping should be insulated or shielded.

PIPING INSULATION

The heat rejected by exhaust piping and the amount of ventilating air required can be substantially reduced by insulating exhaust piping with suitable high-temperature insulation. Exhaust temperatures are given on each generator model's specification sheet. DO NOT insulate piping for the turbocharger or manifold.

WALL THIMBLE

Exhaust piping passing through combustible walls or partitions must be guarded at the point of passage by a metal ventilated thimble to prevent exhaust pipe heat from being transmitted to the combustible material (Figure 6-3). Thimbles must be suitable for the application. Consider the type of exhaust system, construction materials used and local fire codes.

Wall thimbles are usually fabricated at a local sheet metal shop to the specifications furnished by the installation engineer. The thimbles should be constructed so that they extend at least three inches both ways from the surface of the wall or roof. Holes are provided at both ends to allow cooling air to circulate through the thimble. If screening is used on the outer end to keep birds, rodents, etc., from entering the thimble, make sure that the mesh is large enough so that it doesn't impair air circulation through the thimble. If the exhaust pipe must exit through a roof, a rain shield must be included above the thimble. The rain cap as shown on the end of the exhaust pipe is recommended only in areas not subject to freezing temperatures. In an area where freezing is common, extend the exhaust piping well beyond the roof

and use a gradual "U" bend at the end to direct the exhaust outlet downward which will keep rain, snow, etc., out of the pipe. The outlet of the pipe should be far enough from the roof to prevent ignition of the roof material from hot exhaust.

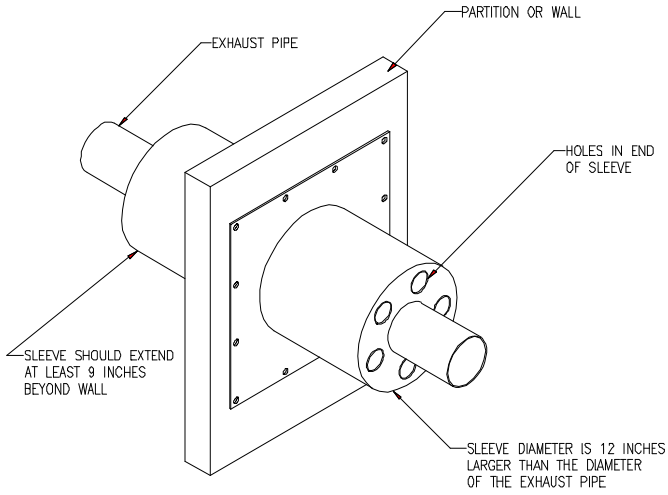

Figure 6-3: Wall thimble installation

TYPE OF FITTINGS (In Inches)	1-1/2	2	2-1/2	3	3-1/2	4	5	6	8	10	12

7 Fuel System

GENERAL

The fuel system must be installed properly to assure availability of fuel for starting and continuous running throughout the emergency. Before connecting the fuel lines to the engine, ensure that fuel connections are free from dirt, grease, water and other contaminants that could damage the engine.

The components comprising a fuel system will differ according to the generator set location, type of fuel and anticipated time of operation desired.

DIESEL APPLICATIONS

The following basic components comprise a representative diesel fuel system:

1. Main Fuel Tank Incorporating:
   a. Fill Line
   b. Vent Line
   c. Supply Line with Foot Valve
   d. Return Line

2. Day Tank (if required)
   a. Pump Control Switch

3. Electric Fuel Transfer Pump (if necessary)

MAIN FUEL TANK

The best location for the main fuel tank is as close to the engine as possible. If building codes and insurance regulations permit, the tank could be located in the same room as the generator set, or in an adjoining room. If this is not possible, the tank should be located outside or underground.

The fuel level in the main tank should be level with the engine's fuel transfer pump inlet. If located in the room, the tank should be on the same general level as the engine's fuel injection pump but lower than the injectors. When the tank must be placed higher or lower than this, it often requires the usage of priming or float tanks. When the main tank can be located close to the set and where the vertical lift is five feet or less, the fuel injection pump may be capable of supplying sufficient fuel. If the horizontal run is too great, or the vertical height exceeds five feet, a transfer pump is required. As a general rule, when static head and dynamic suction (horizontal head) exceed six inches hg (column mercury) an auxiliary pump and tank are required. A float tank or transfer tank is required with the auxiliary pump. The auxiliary pump should be of the positive displacement type, operated electrically from the load side of the transfer switch.

All tanks must be vented to a safe area in the event of an overflow and to allow air and other gases to escape to atmosphere. The vent must, however, prevent dust, dirt and moisture from entering the tank. Return lines are required. Keep the return space at least 12 inches away from the pick-up or fuel supply in the day tank. If this is not done, air bubbles could be entrapped in the fuel and cause erratic operation. At least five percent of capacity should be allowed in a diesel main tank for expansion of the fuel. If the main tank is to be located overhead, an auxiliary fuel shut-off solenoid should be used.

The capacity of the fuel tank will be determined by the fuel consumption of the unit and the continuous operating time necessary. Minimum fuel supply must be sufficient to allow the set to operate for the prescribed number of hours. Before installing a fuel tank, review all local code requirements governing fuel tanks.

The number of lines connected to an underground fuel tank, whose depth of burial exceeds the below grade depth of the electric generating unit, will vary as a function of day tank positioning with regard to the engine and the number of ancillary devices utilized. However, all underground tanks must have the following:

- A vent line terminating above ground level in a screened or hooded type vent cap with unrestricted opening to atmosphere and a safe area, in the event of an overflow, that meets all necessary codes.
- A fuel fill line terminating above grade level, and fitted with an appropriate cap, and terminating in a fuel filler box with an appropriate cap plainly marked for the fuel utilized.
- A fuel supply line connected from the tank to an electric fuel transfer pump is needed when the fuel tank is located below the fuel lifting capacity of the set. The end of the fuel supply line within the tank must be fitted with a foot valve (permits flow in one direction only) to prevent loss of transfer pump prime when the transfer pump is not in operation.
- The day tank should be positioned so that the bottom of the day tank is above the level of the engine fuel filters in order to provide a positive head of pressure for the fuel injection pump, (except for Cummins engines). The mounting of the day tank in this manner will prevent loss of prime to the unit fuel injection pump and is recommended particularly in applications where the unit is utilized as a standby power source. In all applications, the return lines should returned to the main tank.

Local and national regulations governing fuel tank location must be checked before planning the installation. Fuel tanks must be adequately vented to prevent pressurization due to fuel expansion when heated.

CAUTION

The fuel system needs to be sized to handle the fuel flow required by the engine. Engine fuel flow is greater than engine fuel consumption and varies for different engine models. Engine fuel flow and consumption can be found on the model specification sheets located in the Operation and Maintenance manual.

The fill, supply and return lines as well as all diesel fuel system piping must be constructed of black iron pipe. Do not use galvanized pipe for diesel fuel applications.

CAUTION

Galvanized tanks and piping must not be used since the diesel fuel and the galvanized coating react chemically to produce flaking which quickly clogs filters or causes failure of the fuel pump or injectors. Do not use Teflon tape on fuel fittings as it can clog the fuel injectors.

Cast iron and aluminum fittings and pipe should be avoided since they are porous and can leak fuel. Flexible fuel lines must be used to connect the unit to the fuel supply and return lines. Flexible lines must be of the type approved for diesel fuels.

WARNING!

Leaky fuel lines and fuel connections can introduce the possibility of explosion and fire, which can result in injury or death. Ensure fuel lines are properly connected and flexible lines are used between the engine and supply and return lines.

Fuel filters and drains must be located in easily accessible areas to promote regular and frequent service. Cleanliness of the fuel is critical for diesel engines that have easily damaged or clogged precision fuel injectors and pumps.

DAY TANK

The day tank provides a ready supply of fuel at the injector pump. Day tanks are used when the engine pump does not have the necessary lift to draw fuel from the main tank. If the main tank is above the level of the injectors, the day tank is used to remove the fuel head pressure that would otherwise be placed on the engine fuel system components.

When installing the day tank for Cummins engines, make certain the tank is at, or slightly below, the level of the fuel filters to assure maintenance of fuel

system prime. However, the top of the day tank must be below the injector drain connection of the engine.

A slight head of fuel can cause leakage through the injectors and result in hydraulic lock problems, (filling of the engine cylinder with liquid fuel). The injector return line must always be at or below the level of the fitting on the engine. The line must drain toward the day tank.

FUEL OIL TRANSFER PUMP

The fuel oil transfer pump (auxiliary pump) is used to supply fuel from the main tank to the day tank.

Single phase 120 VAC or 240 VAC, the AC power supply for the transfer pump should be taken from the load side of the transfer switch. The pump will operate when its circuit is closed by the action of the level switch.

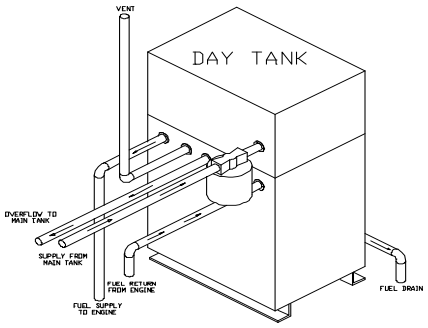

Figure 7-1: Fuel day tank

Fuel is then drawn from the main tank through a foot valve and is pumped into the day tank. Operation continues until the fuel level in the day tank rises causing the float to rise, opening the float switch and disconnecting the pump motor.

DIESEL FUEL RECOMMENDATIONS

Katolight Corporation recommends the use of #2-D diesel fuel.

#2-D Diesel Fuel:
A good quality 40 cetane (min) #2-D diesel fuel is best for most Katolight diesel generator set installations. This must be a distillate fuel which meets the requirements for #2-D in the ASTM diesel fuel classification D-975-60T. Most major brands of fuel oils conform to ASTM specifications.

#1-D Diesel Fuel:
A #1-D grade 40 cetane (min) diesel fuel may be best if operating at altitudes above 5000 feet or in cold weather (below 40° F) conditions. Kerosene is

included in the #1-D class of fuel. This fuel has a lower flash point (more volatile) and is of lower viscosity (flows more freely) than #2-D.

#2 Domestic Type (Furnace) Oil:
#2 domestic or furnace oil may be used. The #2 domestic fuel should have properties as close as possible to that of #2 diesel fuel. Check ASTM D-396-60T. Particular attention must be given to the sulfur content – this must be less than one percent by weight. High sulfur content can lead to increased engine wear and shorter injector life, especially if intermittent operation or low operating temperatures exist.

#4-D Grade Fuel: (NOT RECOMMENDED)
The high sulfur content plus low cetane rating of this class of fuel makes it unsuitable for diesel generator set use.

GASEOUS FUEL SYSTEMS

System Variations: The gaseous fuel systems used can be grouped in four general classifications. The systems are covered in the following sequence:

1. Natural Gas (including manufactured gas)
2. LP Vapor
3. Liquefied Withdrawal
4. Dual Fuel Systems (natural gas and LP gas)
5. Zero Pressure Regulation

1. & 2. NATURAL GAS AND VAPOR PROPANE (FIGURE 7-2A):

Natural, manufactured, sewage and most LP Vapor gas systems are vapor fuels as supplied by the utilities. These fuel system components are used in a similar manner. When the heating content of the fuel falls below 1000 BTU per cubic foot, as it does with manufactured sewage and some natural gas fuels, the set will have to be derated. Check with the factory for application details. The gas distribution companies will provide piping from the main transmission line to the building. The primary regulator should be furnished by the utility company. It is the responsibility of the utility company to insure that sufficient pressure is present at all times to operate the primary regulator. Installation, repair and alteration to gas piping should be undertaken only by the utility company or personnel authorized by them. Piping should be rigidly mounted but protected against damage from vibration. Only UL or AGA approved flexible connection should be used.

3. LIQUID WITHDRAWAL

Most LPG systems are operated from vapor. The main tank is sized to vaporize the fuel volume needed for ambient temperature of the installation. Sizing the LPG tank must be the responsibility of the fuel supplier. Give the fuel supplier the fuel volume required.

Vaporizers: Vaporizers are devices used exclusively with LPG systems. LPG in liquid form is introduced under tank pressure into the vaporizer which uses engine coolant heat to convert the liquid into a vapor state. Vaporizers may be referred to as converters; both names describe its function. There are several types of vaporizers. One type is strictly a vaporizer and must be used in conjunction with other pressure regulators. This type of vaporizer may be required if tank size is limited; low ambient temperatures or high fuel volume are conditions affecting the installation. The type classified as vaporizer-regulators provide vaporization plus primary and secondary regulation of gas pressure.

Fire regulations in most localities prohibit liquid LP high-pressure fuel lines inside a building or enclosure. This automatically precludes high-pressure equipment on or near an engine installed inside a building. Under such regulations, the coolant lines can be extended and the vaporizer mounted outside the structure.

Gas at permissible pressure (usually about 20 psi maximum) is allowed inside the building. The vaporizer must be mounted below the level of the engine water pump and within 25 feet of the engine. If freezing temperatures are common, don't overlook the fact that water inside the vaporizer could freeze unless antifreeze is added to the system.

4. DUAL FUEL SYSTEMS (NATURAL OR LP VAPOR)

In many applications, natural gas is the main fuel and LPG is used as the emergency fuel when natural gas is not available. The dual fuel system (in common use) offers automatic changeover from one fuel to the other.

During operation on natural gas, pressure existing in the common line to the carburetor closes off the LP Vapor regulator. Cutting off the natural gas operates a pressure switch in the line which automatically opens the LP Vapor solenoid and closes the natural gas solenoid.

5. ZERO PRESSURE REGULATION (SEE FIGURE 7-2B)

The Zero Pressure Regulator System works on Zero Pressure air and Zero Pressure gas, the engine vacuum is what mixes the fuel and air through the mixer on the carb.

The system still requires 7 to 11" of water column (4 to 6 ounces) on either Natural Gas or LP Vapor.

The flow control valve is left with the tower in the upright position on either fuel and with the spring left in. The Zero Pressure System only requires the installer to give the correct pressure and volume to the system. NOTE: A dog tag on the system shows the fuel consumption and pressures required for each system.

Gas Piping: Piping must never be used to ground electrical apparatus. Piping must be rigidly mounted but protected against vibration. Where flexible connections are required, use only approved connections. A flexible section should be used between the point where the gas leaves the rigid fuel line and enters the engine.

All gas lines and piping should be of black iron. Joints and connections must be sealed. The pipe should be of sufficient size to maintain the proper pressure level when operating at full load. In addition to the actual fuel consumption, the following factors must be considered:

- Pressure loss due to number of fittings
- Specific gravity of gas
- Pressure loss due to length of piping

At the end of the chapter is a list of steps to follow when calculating pipe capacities for gas flow rates.

This procedure is based on a pressure drop of 0.5" H2O which allows for a normal amount of restriction from fittings.

Table 7-1, Gaseous Fuel Pipe Capacity, lists the capacity of various sizes and lengths of pipe. The capacity (in cubic feet per hour) is calculated using the specific gravity of 0.6 as base. A pressure drop of 0.5" (water column) is used to account for a nominal number of fittings and metering equipment in this table.

Main Components: Solenoid valves used in a gaseous fuel system are designed to close and stop fuel the instant the engine stops. They should not be relied upon to completely seal the fuel system. A ruptured diaphragm or a piece of grit could prevent the valves from sealing. Resulting in gas continuing to flow through the carburetor into the engine and out into the surrounding air. Some gaseous fuels are heavier than air and tend to settle in low areas. This could present a serious hazard, especially in enclosed applications. Safeguards against this should be incorporated in each system.

The common components of a gas system are as follows:

Primary regulator: This regulator is used to provide pressure regulation of the gas from the high-pressure supply line or with LPG with the supply tank.

The primary regulator reduces line pressures to allowable inlet pressures for the secondary regulator. This regulator is supplied by the utility or fuel company.

Secondary regulator: The low-pressure type regulator admits fuel to the engine in response to engine demand similar to the float valve in a gasoline

carburetor. The secondary regulator is not supplied by Katolight and must be supplied by the purchaser. Natural gas and LPG vapor withdrawal inlet pressures must be from four to six ounces per square inch.

PRESSURE REDUCING VALVE

The pressure-reducing valve regulates the volume of fuel to the carburetor. The volume is proportional to the load on the engine.

This device is factory mounted for LP gas vapor withdrawal fuel systems, the valve is inverted and the internal spring removed. Consult factory for drawings showing modifications for propane fuel systems.

Fuel shut-off solenoid: This device automatically shuts off the fuel supply when the engine stops. All Katolight automatic fuel shut-off valves are electrically activated solenoids that seal off the fuel the instant the ignition switch is turned off.

Carburetor: Gas carburetors operate on gaseous fuels only.

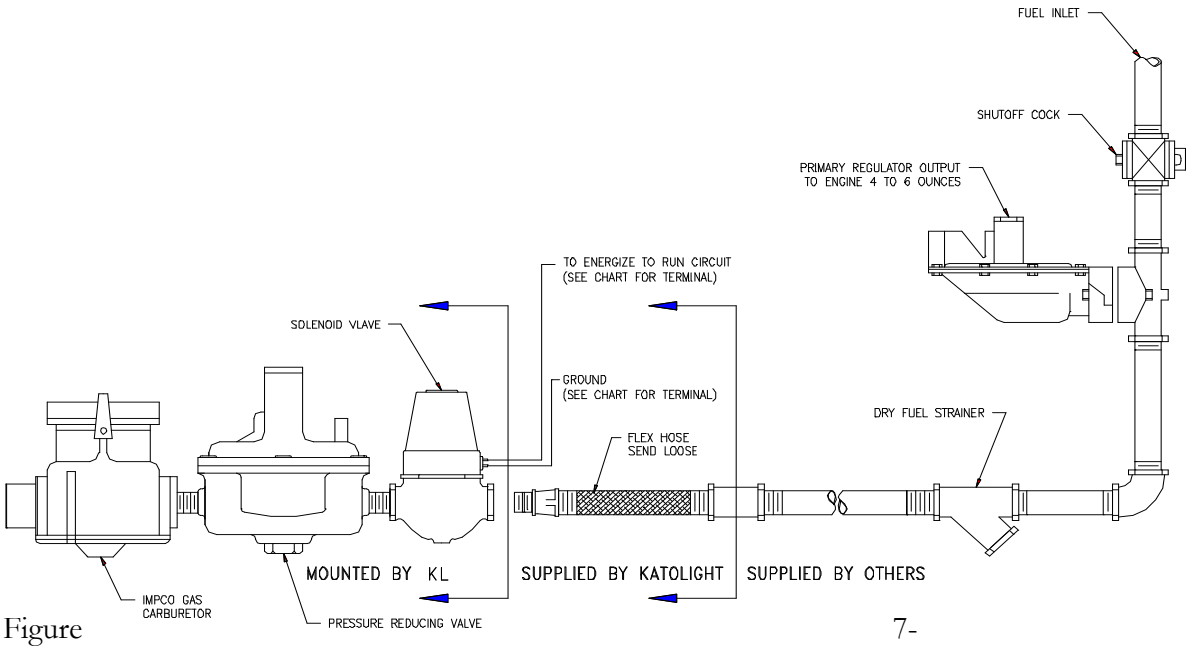

Figure 7-

2A: Gaseous fuel pipe schematic

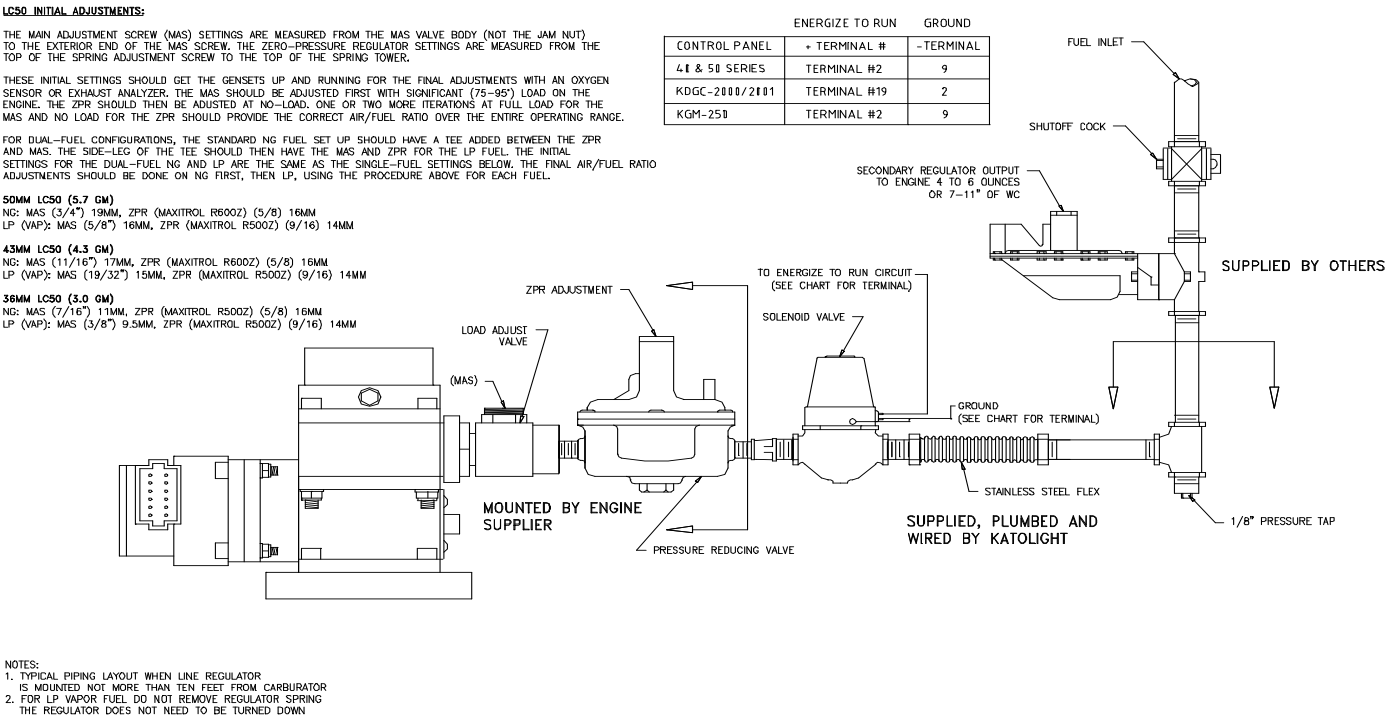

Figure 7-2B: Gaseous fuel pipe schematic with zero pressure regulator

DETERMINING PIPE SIZE FOR GASEOUS FUEL SYSTEMS

1. Obtain the fuel consumption in cubic feet per hour at 100% load from the engine generator model specification sheet for the type of fuel used.
2. Refer to the correction chart below and select the correction factor for the type of fuel used.

Fuel Specific Gravity	Fuel	Correction Factor
.65	Natural Gas	.962
1.00	Air	.775
1.50	Propane	.633
2.10	Butane	.535

3. Divide the fuel consumption from step 1 by the correction factor to obtain adjusted flow rate
4. Determine length of pipe between the fuel source and generator set
5. From table 6.1, choose the column of the nearest pipe length
6. Move down the column until the figure equal to or greater than the adjusted flow rate obtained in step 3 is encountered
7. Move horizontally to the left column to determine the correct pipe size

Iron Pipe Size (in.) Nominal	Length of Pipe (ft.)													
	10	20	30	40	50	60	70	80	90	100	125	150	175	200
1/4	43	29	24	20	18	16	15	14	13	12	11	10	9	8
3/8	95	65	52	45	40	36	33	31	29	27	24	22	20	19
1/2	175	120	97	82	73	66	61	57	53	50	44	40	37	35
3/4	360	250	200	170	151	138	125	118	110	103	93	84	77	72
1	680	465	375	320	285	260	240	220	205	195	175	160	145	135
1-1/4	1400	950	770	660	580	490	460	460	430	400	360	325	300	280
1-1/2	2100	1460	1180	990	900	810	750	690	650	620	550	500	460	430
2	3950	2750	2200	1900	1680	1520	1400	1300	1220	1150	1020	950	850	800
2-1/2	6300	4350	3520	3000	2650	2400	2250	2050	1950	1850	1650	1500	1370	1280
3	11000	7700	6250	5300	4750	4300	3900	3700	3450	3250	2950	2650	2450	2280
4	23000	15800	12800	10900	9700	8800	8100	7500	7200	6700	6000	5500	5000	4600

Table 7.1: Gaseous Fuel Pipe Capacity

EXAMPLE

- Engine – generator set operating with a fuel consumption of 700 cubic feet per hour and at a distance of 50 feet from the fuel supply
- Fuel used is propane and has a specific gravity of 1.5
- Dividing the flow rate of 700 CFH by the correction factor of 0.633 for propane gives the adjusted capacity of 1105 CFH
- Reading down the 50-foot pipe length column in table 6.1 until a figure equal to or greater than 1106 is encountered, we get a figure of 1680
- Reading directly across to the left column gives the required pipe size of 2 inches

8 Electrical Requirements

GENERAL

The electrical system consists of the AC power supplied to the generator and the DC starting and control circuitry. These circuits must be enclosed in separate conduits.

BATTERIES

The batteries need to be provided with enough capacity to provide the cranking motor current specified on the unit specification sheet. The recommended batteries are lead-acid or nickel cadmium. They can be shipped wet or dry. If shipped dry, they can be stored indefinitely and when ready to use filled with electrolyte (acid) with a specific gravity of 1.250 to 1.265. It is recommended that batteries be placed on trickle charge for 12 hours after electrolyte is added.

Batteries should be located as close as possible to the generator set to eliminate line losses.

Nickel cadmium batteries are shipped wet. It is advisable that batteries be placed on trickle charge for 12 hours when received.

Coat battery terminal connections with grease to prevent corrosion. Check the electrolyte level periodically. Make certain all vent caps are in place and unobstructed.

BATTERY RACKS AND CABLES

Where the battery installation requires remote battery location, the correct cross sectional area of battery cables is of importance in minimizing line drop. Battery racks or boxes are supplied by Katolight Corporation for lead-acid batteries.

AC POWER OUTPUT WIRING

All wiring must be in accordance with applicable electrical codes. Wires must be of adequate size, properly insulated and supported in an approved manner. Wires should not be placed where they may interfere with plant operation. Figure 8-1 illustrates the various generator connections for Katolight generators.

WARNING

Accidental contact with electrical equipment can cause severe injury and death if the equipment is not properly grounded. Ensure that all equipment is properly grounded.

AUTOMATIC TRANSFER SWITCH

Installing an automatic transfer switch is primarily an electrical operation and therefore should be handled by a licensed electrician. Instructions and detailed wiring diagrams will accompany the switch.

The transfer switch is designed to be mounted on a wall or other vertical surface free from vibration. The switch should be at the electrical service entrance and yet within 100 feet with No. 12AWG wire from the generator set control cabinet.

REMOTE/AUDIBLE ALARM

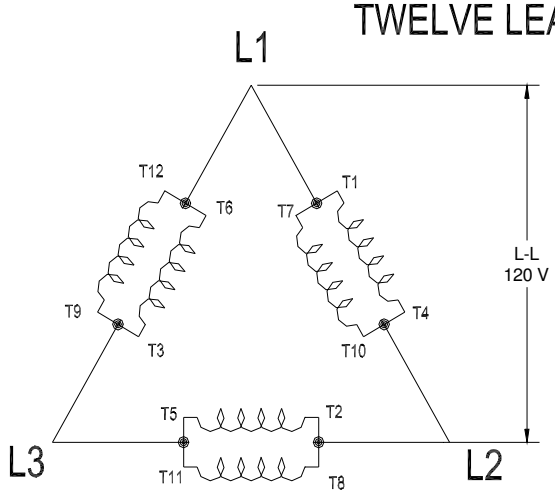
An external fault indicator or audible alarm can be wired to the generator set. Make certain external fault indicator or audible alarm is rated for 2 amperes maximum and 12 or 24 VDC depending on the DC voltage of the system. The indicator will become illuminated or the alarm will sound when an overcrank, low lube pressure, high coolant temperature or overspeed condition occurs.

ACCESSORY WIRING

When motor operated louvers are required for a generator set installation, the louver motors must be wired to operate whenever the engine generator set runs, during emergency conditions, normal periodic exercising, or for maintenance.

Katolight suggests the louver motors be wired to a distribution panel on the load side of the automatic transfer switch. The louver motor control circuit is wired to “energized to run” contacts in the generator set control panel.

TWELVE LEAD PARALLEL DELTA

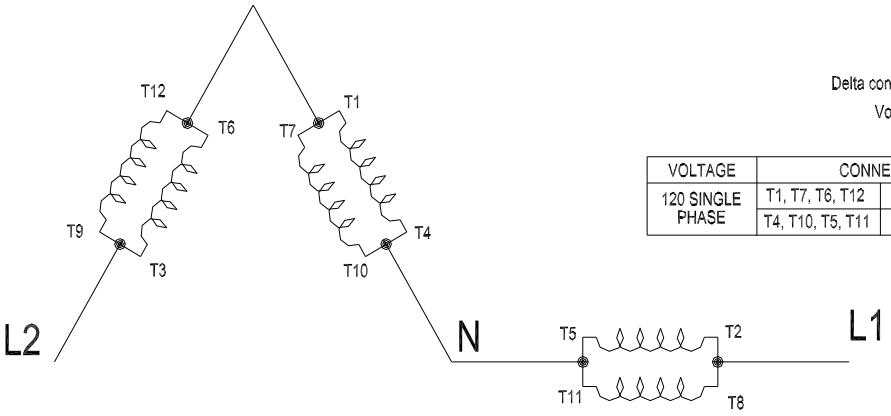


Delta connection with 12 lead generators only.

Voltages: 60 Hz 120v TO 139v
50 Hz 100v TO 120v

VOLTAGE	CONNECT		L1	L2	L3
120 DELTA	T1, T7, T6, T12	T2, T8, T4, T10	T1	T2	T3
	T3, T5, T9, T11				

TWELVE LEAD ZIG-ZAG OR OPEN DELTA

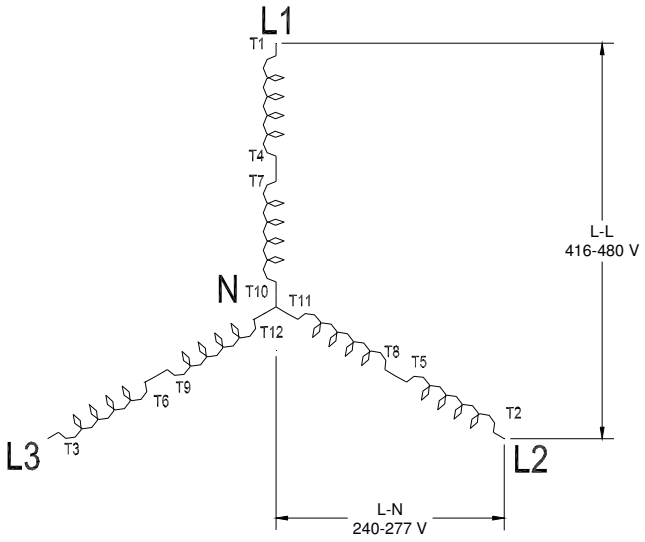


Delta connection with 12 lead generators only.

Voltages: 60 Hz 120/240v single phase
50 Hz 110/220v single phase

VOLTAGE	CONNECT		L1	L2
120 SINGLE PHASE	T1, T7, T6, T12	T3, T9	T2, T8	T3, T9
	T4, T10, T5, T11	T2, T8		

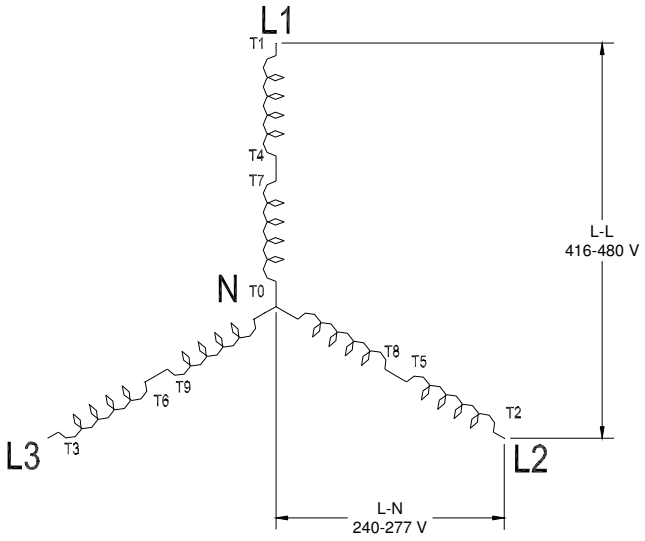
TWELVE LEAD SERIES WYE



Voltages: 60 Hz 240/416v TO 277/480v
50 Hz 220/380v TO 240/416v

VOLTAGE	CONNECT			L1	L2	L3	NEUTRAL
480-416 WYE	T10, T11, T12			T1	T2	T3	T10, T11, T12
	T4, T7	T5, T8	T6, T9				

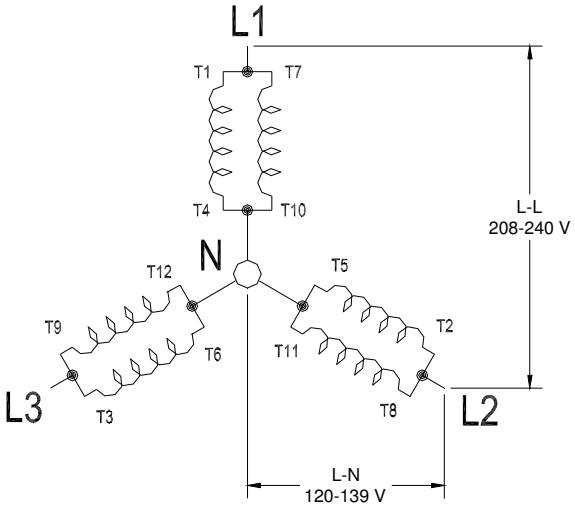
TEN LEAD SERIES WYE



Voltages: 60 Hz 240/416v TO 277/480v
50 Hz 220/380v TO 240/416v

VOLTAGE	CONNECT			L1	L2	L3	NEUTRAL
480-416 WYE				T1	T2	T3	T0
	T4, T7	T5, T8	T6, T9				

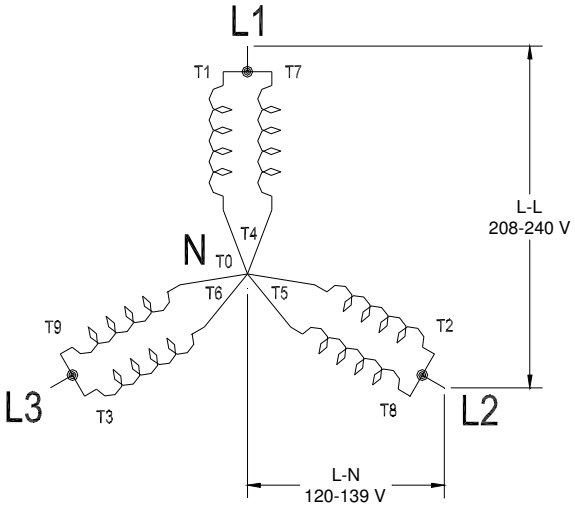
TWELVE LEAD PARALLEL WYE



Voltages: 60 Hz 120/208v TO 139/240v
50 Hz 110/190v TO 120/208v

VOLTAGE	CONNECT			L1	L2	L3	NEUTRAL
240-208 WYE	T10, T11, T12		T4, T5, T6	T1	T2	T3	T10, T11, T12
	T1, T7	T2, T8	T3, T9				T4, T5, T6

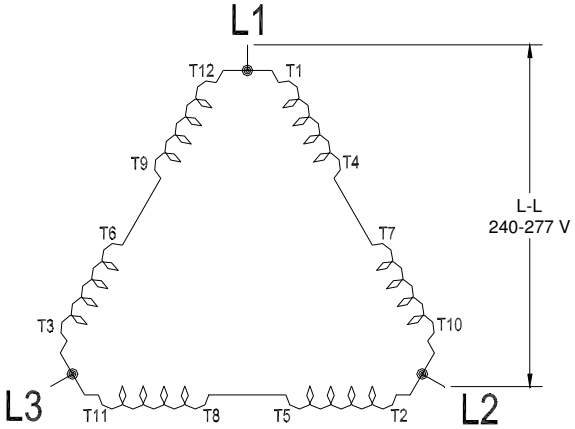
TEN LEAD PARALLEL WYE



Voltages: 60 Hz 120/208v TO 139/240v
50 Hz 110/190v TO 120/208v

VOLTAGE	CONNECT			L1	L2	L3	NEUTRAL
240-208 WYE	T4, T5, T6, T0			T1	T2	T3	T4, T5, T6
	T1, T7	T2, T8	T3, T9				

TWELVE LEAD SERIES DELTA



Voltages: 60 Hz 120/240v TO 138/277v
50 Hz 110/220v TO 120/240v

VOLTAGE	CONNECT			L1	L2	L3
240-277 DELTA	T4, T7	T5, T8	T6, T9	T1	T2	T3
	T1, T12	T2, T10	T3, T11			

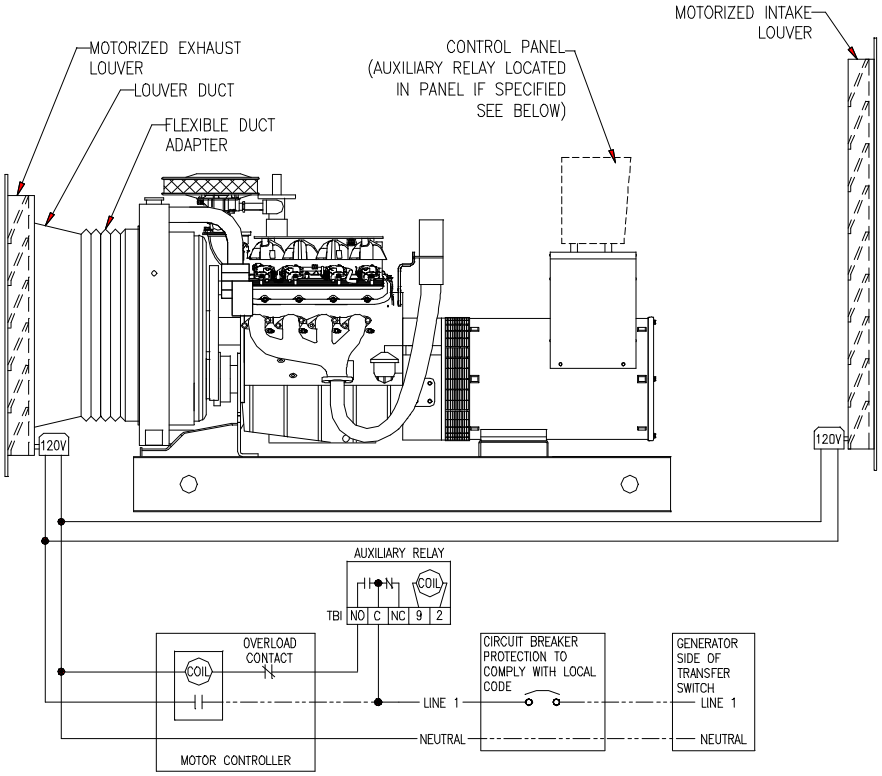


Figure 8-1: Suggested motorized louver wiring

As an alternate-wiring scheme, the louver motor may be wired directly to the generator output leads, prior to the mainline circuit breaker. The installation contractor must add any necessary wiring devices and circuit protection to comply with the local electrical code requirements.

There are many other wiring schemes, which may be used to safely wire the louver motors, and control circuits to insure the louvers will open when the engine generator set runs. If there are any questions, consult your generator set supplier.

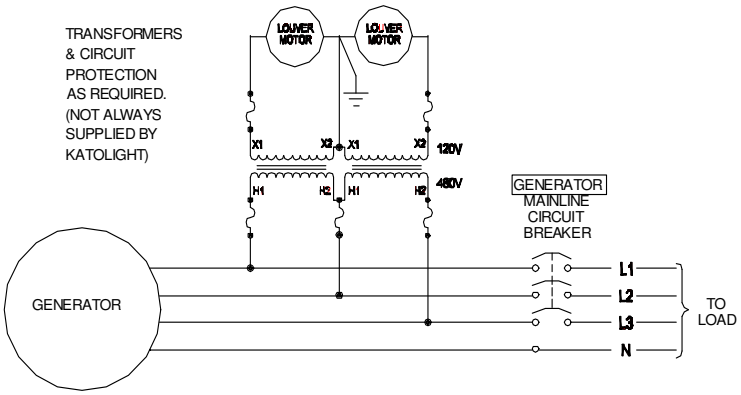

Figure 8-2: Optional motorized louver wiring

9 Service

Install the generator set in an area that can be quickly reached for repair in case of malfunction. Service entrances should be large enough to permit service of components such as engine, radiator or generator in the event major overhaul or replacement is needed.

The location for items requiring service varies from model to model. All service items should be known and considered when planning the installation. An item requiring daily attention must, of course, be made more accessible than one requiring service every 5,000 hours.

In general, the following service points should be accessible:

- Air Cleaner
- Primary Fuel Filter
- Secondary Fuel Filter
- Lube Oil Dip Stick
- Oil Filter
- Starting Battery
- Starter
- Battery Charger & Voltage Regulator
- Generator & Control Systems

If your generator set requires service or repairs, simply contact an authorized Katolight dealer for assistance. Service technicians are factory-trained and are capable of handling all of your service needs.

When contacting a Katolight Authorized Dealer, always supply the complete model number and serial number of your unit, which are located on your generator set nameplate.

To locate the Katolight Authorized Dealer nearest you, call 800-325-5450 or visit www.katolight.com.

NOTE

For standby units, it is important that servicing is performed on a calendar basis. Failure to do this may result in the generator set not starting or operating properly when the unit is most needed. Consult your Operation and Instruction Manual provided with the generator set for servicing information.

10 Installation Checklist

Prior to initial start-up, refer to the following installation checklist to ensure that the generator set is installed properly.

CHECK	OK	CHECK	OK
1. Adequate clearance on all sides.		18. Condensate trap or drain installed.	
2. Adequate incoming air flow.		19. Muffler exhaust flow in right direction.	
3. Adequate outgoing air flow.		20. Exhaust line free of excessive elbows and restrictions.	
4. Radiator duct flange connected.		21. Exhaust line shielded/protected.	
5. Antifreeze required/installed.		22. Battery in cool location.	
6. Water heater properly connected and of proper voltage.		23. Battery properly charged.	
7. Proper size fuel line and connectors.		24. Battery of proper size and voltage.	
8. Fuel lines protected.		25. Battery cables correct size.	
9. Fuel pump lift adequate.		26. Battery charger operating.	
10. Flexible fuel connectors.		27. Generator properly connected.	
11. Fuel return line.		28. All controller contacts clean.	
12. Gas pressure okay.		29. Transfer switch operating correctly.	
13. Solenoid shut-off valve installed (gas).		30. Binding posts tight (all connections).	
14. Proper size exhaust line.		31. Operator has instruction manual.	
15. Flexible exhaust connection installed.		32. Maintenance schedule posted.	
16. Exhaust nipple installed on manifold below flexible exhaust connection (condensate trap).		33. No loose parts, belts, bolts, nuts, etc.	
17. Exhaust piping sloped away from engine.			

11

Start-Up Request Form

To provide an authorized factory start-up at the lowest possible prices, we must request that the following checklist and tasks be completed prior to a Katolight representative's arrival at the installation site to perform the start-up.

Unit Serial Number: _____ Contact Name: _____

Company Name: _____ Title: _____

Please attach a map or directions to the site. Phone Number: _____

- ☐ Unit set in place on vibration pads with floor anchor/studs to prevent movement.
- ☐ Radiator ducted to properly sized air discharge louvers.
- ☐ Unit full of oil and water/anti-freeze mix.
- ☐ Battery filled with acid and fully charged.
- ☐ Battery charger mounted with AC and DC wired, if not supplied mounted by the factory.
- ☐ All AC and DC electrical connections made.
- ☐ Engine heater wired to normal AC power supply.
- ☐ Fuel inlet and return lines run between the unit and fuel storage system, system filled and primed to the engine with proper fuel.
- ☐ Exhaust system in place and supported so that the exhaust manifold does not carry weight of exhaust system.
- ☐ Air inlet louver motor wired to an emergency generator source point to open upon the start of an engine generator set.
- ☐ Generator room cleaned of construction debris including excess nails, bolts, nuts, panel knockouts, etc. It is very important that the radiator fan area is checked for debris, as damage to the equipment and personal injury can occur if loose items come in contact with the fan when the unit is initially started.

Consult your Katolight Installation Guide on any questions.

If, upon arrival at the installation site, our representative cannot perform the start-up as a result of defective Katolight equipment, the problems will be resolved and we will reschedule another start-up date at the earliest possible date at no additional charge.

If the start-up cannot be performed due to an incomplete installation or for reasons beyond Katolight's control, you may incur an additional start-up charge at a later date.

CALIFORNIA

Proposition 65 Warning Diesel engine exhaust and some of its constituents are known to the State of California to cause cancer, birth defects, and other reproductive harm.

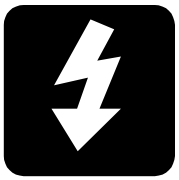
IMPORTANT SAFETY INSTRUCTIONS

SAVE THESE INSTRUCTIONS – This manual contains important instructions that should be followed during installation and maintenance of the generator and batteries

SAFETY PRECAUTIONS

Before operating the generator set, read the operators manual! Become familiar with the equipment and safe operating procedures. Safe operation can be achieved only if the equipment is properly operated and maintained.

Dangers, Warnings and Cautions are used in this publication to alert the operator to special instructions concerning a particular procedure that may be hazardous if performed incorrectly. These "Safety Alerts" alone can not eliminate the hazards that they signal. Strict compliance to these special instructions when performing the service, plus "common sense" operation, are major accident prevention measures. Katolight Corporation can not anticipate every possible circumstance that might involve a hazard. The warnings in this Manual and on tags and decals affixed to equipment are, therefore, not all-inclusive.



This symbol signifies high voltage.

The following safety rules should be strictly complied with:

The standby electric system must be installed, tested, and inspected per the manufacturer's recommendations. All codes, standards, regulations, and laws pertaining to the installation must be strictly complied with.

DANGEROUS voltages are present at power terminals of this equipment. Contact with such terminals will result in extremely dangerous and possibly lethal electric shock. Never allow any unqualified person to install, operate or service the equipment.

! CAUTION ! RISK OF ELECTRIC SHOCK!

The grounded conductor must be bonded to ground in accordance with the National Electric Code, NFPA 70. The unit shall not be used in floating output applications.

! CAUTION !

The frame and external electrically conductive parts of this equipment must be properly connected to an approved earth ground, in accordance with applicable electrical codes. A grounding lug is provided on the generator and in other equipment for this purpose.

WARNING

Accidental contact with electrical equipment can cause severe injury and death if the equipment is not properly grounded. Ensure that all equipment is properly grounded.

Gaseous, Natural Gas and Liquid Propane Gas are extremely flammable and vapors are ***EXPLOSIVE.***

Diesel fuel is highly flammable. Comply with all laws regulating the storage and handling of these fuels. Check for leaks frequently and correct such leakage immediately.

Engine exhaust gases contain ***DEADLY*** carbon monoxide gas. If breathed in sufficient concentrations, this gas can cause unconsciousness or even death. Provide adequate ventilation to prevent buildup of exhaust gases. When the generator is installed inside a room or enclosure, exhaust gases must be piped outdoors. Install the exhaust system so exhaust gas does not leak at joints or piping connections. The exhaust manifold, turbocharger(s), and extended exhaust piping are ***HOT*** when the engine is running. These can remain hot for long periods of time after the engine shuts off. Avoid contact with these parts. Consider insulating the exhaust system if installation is such that unintentional contact with the exhaust system components is likely.

Coolants under pressure have a higher boiling point than water. ***DO NOT*** open a radiator or heat exchanger pressure cap while the engine is running. Allow the generator set to cool and bleed the system pressure first.

Wear protective safety eyeglasses and gloves when handling starting batteries and electrolyte. Battery acid can cause serious burns if it contacts eyes and skin.

Servicing of batteries is to be performed or supervised by personnel knowledgeable of batteries and the required precautions. Keep unauthorized personnel away from batteries.

CAUTION-The replacement starting battery or batteries must be of equal size and cold cranking amps. Observe all precautions listed below.

CAUTION-The generator controls must be in the off position when replacing the batteries.

CAUTION-Do not dispose of battery or batteries in a fire. The battery is capable of exploding.

CAUTION-Do not open or mutilate the battery or batteries. Released electrolyte has been known to be harmful to the skin and eyes and to be toxic.

CAUTION-A battery presents a risk of electrical shock and high short circuit current. The following precautions are to be observed when working on batteries:

1. Remove watches, rings, or other metal objects.
2. Use tools with insulated handles.

Vented Batteries

The installation of the engine generator shall provide enough ventilation to ensure that gases generated by vented batteries during charging or caused by equipment malfunction are removed.

CAUTION-The electrolyte is a dilute sulfuric acid that is harmful to the skin and eyes. It is electrically conductive and corrosive. The following procedures are to be observed:

1. Wear full eye protection and protective clothing.
2. Where electrolyte contacts the skin, wash it off immediately with water.
3. Where electrolyte contacts the eyes, flush thoroughly and immediately with water.
4. Spilled electrolyte is to be washed down with an acid-neutralizing agent. A common practice is to use a solution of one pound (500 grams) bicarbonate of soda solution is to be added until the evidence of reaction (foaming) has ceased. The resulting liquid is to be flushed with water and the area dried.

CAUTION-Lead acid batteries present a risk of fire because they generate hydrogen gas. The following procedures are to be followed:

1. DO NOT SMOKE when near batteries.
2. DO NOT cause flame or spark in battery area.
3. Discharge static electricity from body before touching batteries by first touching a grounded metal surface.

Moving parts can cause severe personal injury or death. Do not wear loose clothing or jewelry in the vicinity of moving parts, or while working on

electrical equipment. Loose clothing and jewelry can become caught in moving parts. Jewelry can short out electrical contacts and cause shock or burning.

Remove all unnecessary grease and oil from the unit. Accumulated grease and oil can cause overheating and engine damage, which present a potential fire hazard.

When an open bottom is used, instructions shall state that the stationary engine generator assembly is to be installed over noncombustible materials and shall be located such that it prevents combustible materials from accumulating under the generator set.

OPERATION PROCEDURES

Installation Procedures: Refer to Katolight's "Installation Guide"

! CAUTION !

The high engine temperature shutdown system will not operate if the coolant level is too low. The high engine temperature sensor monitors coolant temperature. Loss of coolant will prevent sensor operation and allow the engine to overheat causing severe damage to the engine. Therefore, maintain adequate coolant level for proper operation of the high engine temperature shutdown system.

Low Coolant Level Shutdown – A submerged sensor in the top portion of the radiator shuts down the engine and lights the Hi Engine Temp fault lamp when the coolant level falls below the level of the sensor. Top off coolant frequently.

Prior to starting or testing the generator set refer to the engine manual for maintenance checkpoints. Items such as oil level, coolant level, belt tension, battery electrolyte level, wire connections, air filter are some of those that should be checked frequently.

! CAUTION !

Stop engine before filling fuel tank. Never fill tank when engine is hot.

STARTING PROCEDURE

The following sections cover the three systems used to start the generator set. See Pages 8 – 14 for panel description and illustrations.

Starting at Control Panel
Move the RUN/OFF/AUTO switch on the control panel to the RUN position. This will activate the engine control system and the starting system. The starter will begin cranking and after a few seconds the engine should start. The starter will disconnect when the engine reaches a speed of 500-750 RPM. If the engine does not start, the starter will disengage at the end of the cranking cycle. Katolight generator sets with the cycle cranking will crank for 10 seconds and then rest

for 10 seconds until 5 cycles have been completed, then lock out on overcrank (fail to start). To clear an overcrank fault, place the RUN/OFF/AUTO switch in the OFF position. Wait two minutes for the starter motor to cool and

then repeat the starting procedure. If the engine does not run after a second attempt at starting, refer to the Troubleshooting section.

Automatic Starting
Place the RUN/OFF/AUTO switch on the generator set control panel in the AUTO position if an automatic transfer switch is used. This allows the transfer switch to start the generator set if a power outage occurs and stop it when the power returns. **Be aware the genset could start at any time in the "AUTO" mode – keep clear of all moving parts and be sure to turn switch to "OFF" position before servicing and disconnect the negative battery cable after disconnecting the battery charger circuit.**

STOPPING

Before Stopping
Run the generator set at no load for three to five minutes before stopping. This allows the lubricating oil and engine coolant to carry heat away from the combustion chamber and bearings.

To Stop
If the set was started at the set control panel or at a remote control panel, move the RUN/OFF/AUTO switch or remote starting switch to the OFF position. If an automatic transfer switch started the set, the set will automatically stop after the normal power source returns, and time delays have been satisfied.

BREAK-IN

Drain and replace the crankcase oil and oil filter(s) after the first 30 to 50 hours of operation on new generator sets. Refer to the MAINTENANCE section of the Engine manual for the recommended procedures. It is recommended to achieve the break in during the first 2 months after installation is completed. This will familiarize the operator with the system.

NO-LOAD OPERATION

Periods of no load operation should be held to minimum. If it is necessary to keep the engine running for long periods of time when no electric output is required, best engine performance will be obtained by connecting a “dummy” electrical load. Such a load could consist of Load Banks.

EXERCISE PERIOD

Generator sets on continuous standby must be able to go from a cold start to being fully operational in a matter of seconds. This can impose a severe burden on engine parts. Regular exercising keeps engine parts lubricated, prevents oxidation of electrical contacts and in general helps provide reliable engine starting. Exercise the generator set at least once a week for a minimum of 30 minutes with load so the engine reaches normal operating temperatures. The Automatic Transfer switch has an optional exerciser that can be preset to provide regular exercise periods. Typically the exerciser can be set for time of start, length of run, and day of week.

LOW OPERATING TEMPERATURES

Use a coolant heater if a separate source of power is available. The optional heater will help provide reliable starting under adverse weather conditions.
Be sure the voltage of the separate power source is correct for the heater element rating. The heater should be in use year round. A heater is required on all automatic systems to prevent engine damage due to short warm up cycles.

AUTOMATIC TRANSFER SWITCH

! DANGER !

HAZARDOUS VOLTAGE
Will cause severe injury or death.
Turn OFF all power before installation, adjustment or removal of transfer switch or any of its components.

EQUIPMENT INSPECTION

Immediately inspect the transfer switch when received to detect any damage, which may have occurred during transit. If damage is found or suspected, file claims as soon as possible with the carrier and notify the nearest Katolight representative. The switch cabinet should be opened at inspection to check for internal freight damage, even if the box and cabinet enclosure appear undamaged.

FINAL EQUIPMENT INSPECTION

Prior to energizing the transfer switch:

Remove any debris incurred due to shipment or installation. DO NOT use a blower since debris may become lodged in the electrical and mechanical components and cause damage. Use of a vacuum is recommended.

Verify that all cabled connections are correct. Verify phase rotation and position of the high leg at both sources on the delta system.

Check engine start connections and verify the correct connection of all control wires.

Check settings of all timers and adjust as necessary. Also adjust any optional accessories as required.

Check the integrity of power connections by verifying actual lug torque values as specified in the ATS manual.

Make sure that all covers and barriers are installed and properly fastened.

FUNCTIONAL TEST

Since there are various transfer switch designs available, please refer to the operator manual provided with the transfer switch for specific details.

The functional testing of the transfer switch consists of electrical tests described in this section. Before proceeding, refer to the information package supplied with the transfer switch. Read and understand all instructions and review the operation of all accessories provided.

Before starting the operation test, check the equipment-rating nameplate on the transfer switch to **verify the correct system voltage.**

To begin the test, close the Normal source circuit breaker. The micro-controller will illuminate the Normal Available LED if proper voltage is sensed. Verify the phase-to-phase voltages at the Normal line terminals.

Next, close the Emergency source breaker and start the engine generator. The Emergency Available LED indicator will illuminate when preset voltage and frequency levels are achieved. Check the phase-to-phase voltages at the Emergency line terminals. Also, verify that the phase rotation of the Emergency source is the same as the phase rotation of the Normal source.

After the sources have been verified, shut down the engine generator, and put the starting control in the automatic position. Complete the visual inspection of the transfer switch, and close and lock the cabinet door.

Initiate the electrical transfer test by activating the test switch. **Hold the test switch until transfer to Emergency is accomplished.** After the engine start time delay, the micro-controller will send an engine start signal and sensing will determine when the auxiliary source reaches preset levels. The switch will transfer to the Emergency source after the time delay of the transfer to the Emergency timer.

Deactivating the test switch will start retransfer to the Normal source. The switch will retransfer to the Normal source after the time delay of the retransfer to Normal timer. The engine over-run timer allows the engine generator to run unloaded for a preset cool-down period.

For complete details of timer and voltage sensing operations, please refer to the Automatic Transfer Switch Operation Manual.

MAINTENANCE AND TESTING

A preventive maintenance program will insure high reliability and long life for the transfer switch. The preventive maintenance program for the transfer switch should include the following items.

INSPECTION AND CLEANING

! DANGER !

HAZARDOUS VOLTAGE
De-energize all sources of power before doing any work on the transfer switch. Note: If approved disconnects are not in place contact your Local Electric Utility or a qualified Electrician before proceeding.

The switch should be inspected for any accumulation of dust, dirt, or moisture, and should be cleaned by vacuuming or wiping with a dry cloth or soft brush. DO NOT use a blower since debris may become lodged in the electrical and mechanical components and cause damage.

Remove the transfer switch barriers and check the condition of the contacts. Any surface deposits must be removed with a clean cloth (DO NOT USE EMERY CLOTH OR A FILE). If the contacts are pitted or worn excessively, they should be replaced. A general inspection of mechanical integrity should be made to include loose, broken or badly worn parts.

SERVICING

All worn or inoperative parts must be replaced using recommended replacement parts. Please refer to the Replacement Parts manual for specific part information and ordering procedures. Please contact your nearest Distributor.

The operating mechanism of the transfer switch is lubricated. The lubricant applied at the factory provides adequate lubrication for the lifetime of the switch. Should debris contaminate the mechanism, clean and apply additional lubricant. (See Automatic Transfer Switch Manual for proper lubricant type).

TESTING

A manual operator handle is provided with the transfer switch for maintenance purposes only. Manual operation of the switch must be checked before it is operated electrically. Both power sources MUST be disconnected before manual operation of the switch. Insert the handle and operate the transfer switch between the Normal and Emergency positions. The transfer switch should operate smoothly without binding. Return the switch to the Normal position, remove the handle, and return it to the holder provided.

After completing the inspection, cleaning and servicing of the transfer switch, reinstall the switch cover, and close and lock the cabinet door. Reclose the circuit breakers feeding the utility and generator sources to the switch.

Initiate the electrical transfer test by activating the test switch. Engine start timer will time out and the micro-controller will send an engine start signal. When the transfer to Emergency time has elapsed, the switch will complete its transfer by closing into the Emergency source.

Deactivating the test switch will start retransfer to the Normal source. The switch will complete its retransfer to Normal after the time delay of the retransfer to Normal timer. The engine over-run timer allows the engine generator to run unloaded for a preset cool down period.

GOVERNORS

MECHANICAL GOVERNOR ADJUSTMENTS

All Katolight Gen-Sets are tested at full load prior to shipment and the speed settings are adjusted. The typical settings will vary from 60 – 63 Hz at no load and are set to operate at 60 Hz when loaded to the nameplate rating. If the system load does not reach the nameplate rating the speed can be adjusted down to 60 Hz. Care must be taken to insure that the Katolight Gen-Set operates at no less than 60 Hz when the entire load to be on the unit is applied. See Figures 2 – 1 and 3 – 1 to find the typical speed adjust locations.

ELECTRONIC GOVERNOR DIESEL ADJUSTMENTS

Governor Speed Setting (Diesel)

The governed speed set point is increased by clockwise rotation of the Speed adjustment control. Remote speed adjustment can be obtained with an optional Speed Trim Control. See Figure 1 –1.

Governor Performance (Diesel)

Once the engine is at operating speed and at no load, the following governor performance adjustments can be made: Rotate the Gain adjustment clockwise until instability develops. Gradually move the adjustment counterclockwise until stability returns. Move the adjustment 1/8 of a turn further counterclockwise to insure stable performance.
Rotate the Stability adjustment clockwise until instability develops. Gradually move the adjustment counterclockwise until stability returns. Move the adjustment 1/8 of a turn further counterclockwise to insure stable performance.
Gain and stability adjustment may require minor changes after engine load is applied. Normally, adjustments made at no load achieve satisfactory performance. A strip chart recorder can be used to optimize the adjustments further. If instability cannot be corrected or further performance improvements are required, contact the nearest distributor or Service Center.

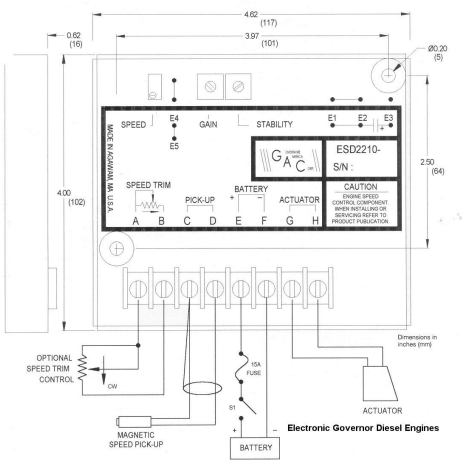


FIGURE 1-1
STANDARD GAC GOVERNOR CONTROL

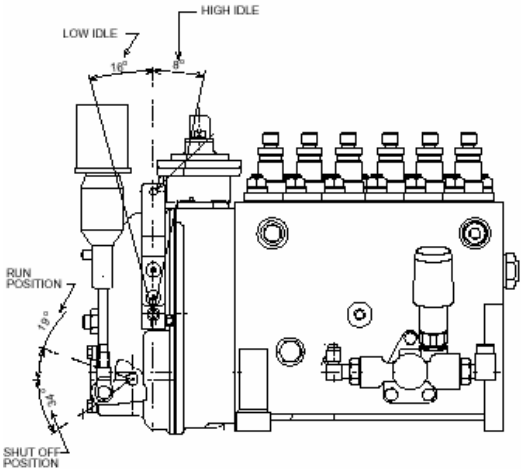

FIGURE 2-1
STANDARD MECHANICAL GOVERNOR FOR DIESEL ENGINES.

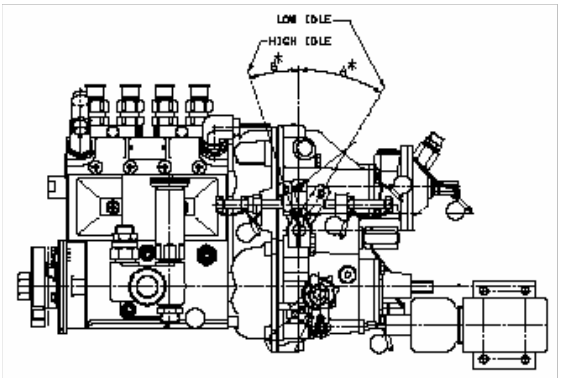

FIGURE 3-1
STANDARD MECHANICAL GOVERNOR FOR DIESEL ENGINES

Gas Engine Governor System

The gaseous engines utilize an electronic governor as standard. The governors are microprocessor controlled and have no operator accessible adjustments. The speed is factory set to operate at 60.1 hertz.

TROUBLESHOOTING

The generator set has a number of sensor units that continuously monitor the engine for abnormal conditions such as low oil pressure or high coolant temperature. If an abnormal condition does occur, the engine monitor will activate a fault lamp and may also stop the engine depending on the condition. If the generator set does shut down, the operator may be able to restart the set after making certain adjustments or corrections. This section describes the operation of the fault condition system and suggested troubleshooting procedures for the operator.

Safety Considerations
High voltages are present within the control panel and generator outlet box when the generator is running.

! WARNING !

Contacting high voltage components can cause serious personal injury or death. Keep control and outlet box covers in place during troubleshooting.

Generator set installations are normally designed for automatic starting or remote starting. When troubleshooting a set that is shut down make certain the generator set cannot be accidentally restarted. Place the RUN/OFF/AUTO switch in the OFF position and remove the negative battery cable from the starting battery. Also, be sure to turn battery charger disconnect off before servicing battery circuits.

! WARNING !

Accidental starting of the generator set during troubleshooting can cause severe personal injury or death. Disable the generator set before troubleshooting.

When a fault comes on during operation the type of fault will be displayed on the LCD panel. The control panel will also illuminate an indicator light to correspond with the display. The red LED light will indicate fault (shutdown alarm) or the yellow LED pre-alarm (approaching shut down point).

Display Mode Switch
This switch allows the operator to lock the display by moving the switch upward when in the scroll lock mode, the display will not update. By moving the toggle downward the display will show total run time. When the mode switch is in the mid position (normal mode), the display will scroll through all parameters. Follow the trouble shooting procedures to locate and correct the problem. For any symptom not listed, contact your Distributor for service. Voltage and amperage may display 3 phases, when operated single phase. The unused positions will display “0”.

Resetting the Control
Placing the RUN/OFF/AUTO switch in the OFF position and pressing the alarm silence switch can deactivate the external alarm and fault lamp. Locate the problem and make the necessary corrections before restarting the generator set.

Main Line Circuit Breaker
The generator output mainline circuit breaker is mounted inside the generator outlet box. If the load exceeds the breaker current rating, the breaker will open to prevent the generator from being overloaded. If the circuit breaker trips, locate the source of the overload and correct as required. Manually reset the breaker to reconnect the load to the generator, by pushing the handle down to the open OFF position, then up to the closed ON position.

TROUBLESHOOTING

! WARNING

Many troubleshooting procedures present hazards, which can result in severe personal injury or death. Only qualified service personnel with knowledge of fuels, electricity, and machinery hazards should perform service procedures. Review safety precautions on inside cover page.

SYMPTOM As Indicated on Display Screen	CORRECTIVE ACTION
1. PRE HI ENGINE TEMP. Engine continues to operate.	**1.** Indicates engine has begun to overheat and engine temperature has risen to approximately 215°F (102°C). If generator is powering non-critical and critical loads and cannot be shut down. Use the following: a. Reduce load if possible by turning off non-critical loads. b. Check air inlets and outlets and remove any obstructions to airflow. c. Open doors or windows in generator area to increase ventilation. If engine can be stopped, follow procedure in Step 2.
2. HI ENGINE TEMP LED. Engine shuts down.	**2.** Indicates engine has overheated (engine temperature has risen above 225°F/107°C) or coolant level is low (sets with coolant level sensor). Allow engine to cool down completely before proceeding with the following checks: a. Check coolant level and replenish if low. Look for possible coolant leakage points and repair if necessary. b. Check for obstructions to cooling airflow and correct as necessary. c. Check for a slipping fan belt and tighten if loose. d. Reset control and restart after locating and correcting problem. Contact your Dealer or Distributor if none of the above.

3. PRE LOW OIL PRESSURE. Engine continues to operate.	**3**. Indicates engine oil pressure has dropped to 20 psi (138kPa). If generator is powering critical loads and cannot be shut down, wait until next shutdown period and then follow Step 4 procedure. If engine can be stopped, follow procedures in Step 4.
4. LOW OIL PRESSURE. Engine shuts down. **NOTE:** See also Step 5	**4.** Indicates engine oil pressure has dropped to 15 psi (103kPa). Check oil level, lines and filters. If oil system is okay, but oil level is low, replenish. Reset control and restart. Contact your Dealer or Distributor if oil pressure is not in the range of 35 to 55 psi (241 to 379 kPa).
5. OVERCRANK. Engine stops cranking. Or Engine runs, shuts down, and LOW OIL PRESSURE.	**5.** Indicates possible fuel system problem. a. Check for empty fuel tank, fuel leaks, or plugged fuel lines and correct as required. b. Check for dirty fuel filter and replace if necessary (See Maintenance section of Engine Manual). c. Check for dirty or plugged air filter and replace if necessary (See Maintenance section of Engine Manual). d. Refer to Step 4. e. Reset the control and restart after correcting the problem. Contact your Dealer or Distributor for service if none of the above.
6. OVERSPEED, Engine runs and then shuts down.	**6** Indicates engine has exceeded normal perating speed. Refer to governor adjust procedure. Contact your Dealer or Distributor for service.
***7.** UNIT NOT IN AUTO.	**7.** Indicates AUTO/OFF/RUN switch is in the OFF position which will prevent automatic starting if an automatic transfer switch is used. Move the AUTO/OFF/RUN switch to the AUTO position for automatic starting.
8. LOW FUEL. Engine continues to run.	**8.** Indicates diesel fuel supply is running low. Check fuel supply and replenish as required.
9. LOW FUEL and LOW OIL.	**9.** Indicates engine has run out of fuel. Check fuel level and replenish as required. See Engine Manual for fuel system priming procedure.

10. LOW ENGINE TEMPERATURE. Set is in standby mode but not operating.	**10.** Indicates engine coolant heater is not operating or is not circulating coolant. Check for the following conditions: a. Coolant heater not connected to power supply. Check for blown fuse, open circuit breaker or disconnected heater cord and correct as required. b. Check for low coolant level and replenish if required. Look for possible coolant leakage points and repair as required. c. Contact your Dealer or Distributor if none of the above.
11. Engine starts from generator control panel, but will not start automatically or from a remote panel. (Note: The AUTO/OFF/RUN switch must be in the AUTO position.) Automatic or remote starting	**11.** Indicates possible fault with remote start circuit. Check the following: a. Check wire to ATS. b. See ATS section for further troubleshooting. c. Contact your Dealer or Distributor for assistance.
12. Engine will not crank.	**12.** Indicates possible fault with control or starting system. Check for the following conditions: a. Fault lamp on. Correct fault and reset control. b. Poor battery cable connections. Clean the battery cable terminals and tighten all connections. c. Discharged or defective battery. Recharge or replace the battery. d. Contact your Dealer or Distributor for assistance if none of the above.
13. No AC output voltage.	**13.** Indicates possible fault with voltage regulator. a. Verify output with another meter if ok check meter, if ok check meter fuses. b. Regulator fuse is blown. Replace fuse. Contact your Dealer or Distributor if voltage build-up causes fuse to blow. c. Check rotating rectifier for damaged diodes. Replace all diodes if any are failed.

14. No Engine Start	**14.** Indicates Engine Start wires not terminated properly or Generator in OFF position. a. Check Engine Start connections. b. Investigate why Engine Control Switch was put in off. c. Contact your Dealer or Distributor for assistance.
15. No Engine Stop	**15.** Indicates Timing Cycle not complete, Engine Start wires not terminated correctly or Generator in RUN. a. Check Engine Start Timer setting. b. Check Engine Start Connections. c. Investigate why the Engine Control Switch was put in Manual. d. Contact your Dealer or Distributor for assistance.
16. ATS will not transfer to Emergency	**16.** Indicates Emergency voltage or frequency not within acceptable parameters, Power supply harness unplugged, Limit Switch harness unplugged or Timing Cycle not complete. a. Check Engine Start connections, Generator output, and Engine Control Switch. b. Plug in Power Supply harness. c. Plug in Limit Switch harness. d. Check transfer to Emergency Timer setting. e. Contact your Dealer or Distributor for assistance.
17. ATS will not transfer to Normal	**17**. Indicates Normal voltage or frequency not within acceptable parameters, Power Supply harness unplugged, Limit Switch harness unplugged or retransfer to Normal timing cycle not complete. a. Check Utility and Utility breakers. b. Plug in Power Supply harness. c. Plug in Limit Switch harness. d. Check retransfer to Normal Timer setting. e. Contact your Dealer or Distributor for assistance.

Operating Instructions

MANUAL START:

If the Engine-Generator Set is located in a closed space, start the ventilation fan or open the doors and windows to allow an ample supply of air to the unit.

A. Place the generator circuit breaker in the **OPEN** position.
B. Put the engine control in the **MANUAL / RUN** position.
   NOTE: If the engine does not start, check the Operator's Manual.

MANUAL:

C. Check the unit frequency. Speed should be 3 to 5 % of rated speed (60 Hz). If not, refer to Operator's Manual for governor adjustment.
D. Check the unit AC voltage. (If the AC voltage is not reading correct, refer to the Operator's Manual for the proper procedure to adjust the voltage regulator to the rated voltage.)
E. Check engine parameters, via gauges or by scrolling through the microprocessor control panel for proper readings.
F. Close the generator circuit breaker.

The Engine-Generator Set is now ready to supply power to the load and will continue to supply power until the operator shuts down the set or an engine failure occurs.

MANUAL SHUTDOWN:

A. Open the generator circuit breaker, move handle to the **DOWN** position.
B. Put the engine control in the **OFF** position.
   NOTE: Following daily service or other maintenance on generator set, place the engine control to desired operating mode. When desired operating mode is automatic, reset the generator circuit breaker by placing its handle in the **UP** position.

EMERGENCY STOP PUSH BUTTON: (OPTIONAL EQUIPMENT)

In case of emergency the operator may shutdown the generator set by pushing the red mushroom head button. If equipped, this is located in the lower right corner of the control panel. This will stop and lock out the generator set. The push button's red light will also turn on to indicate the generator was stopped, by initiating the emergency stop button. The red push button must be pulled out to reset the generator set and turn off the red indicating light. Place the engine control to the "OFF" position to reset the engine control before restarting the unit. Reset the main line circuit breaker before returning the generator set to "AUTOMATIC" operation.

AUTOMATIC OPERATIONS

For automatic operation the Engine-Generator Set will be controlled by the automatic transfer switch and the automatic engine control.

A. For detailed operations of the transfer switch, refer to the Operations Manual supplied with the transfer switch.

B. For detailed operations of the automatic engine control, refer to Operations Manual, supplied with the Genset.

I. Standby State

(a) Leave the engine control in the “AUTO” position.
(b) Leave the generator set circuit breaker in the “ON” position.

II. Power Fails

(a) The remote start contact in the transfer switch will close and complete a circuit to the automatic start control terminals marked “E” in the control panel.
(b) This will cause the engine to start and come up to speed and voltage, then transfer to the load to the Engine-Generator Set.

III. Power Returns

(a) The load transfers back to normal power after a time delay (if provided).
(b) The remote start contact in the transfer switch will open after a time delay (if provided), and the unit will shutdown and be ready for the next power failure.

Rev. 20030530

KATOLIGHT CORPORATION

WEEKLY CHECK LIST EXPLANATION

Rev. 20030530

Date:	- fill in the date of the inspection.
Ambient Temp:	- record outside or room air temperature.
Oil Level:	- record the level from the oil dipstick and the amount of oil added to engine if it was needed.
Water Level:	- record the level of the water in radiator and the amount of water added to radiator if it was needed.
Heaters:	- feel the block heater inlet and outlet hoses to make sure they are warm.
Belts:	- check belts to make sure they are tight. You cannot hear loose belts over the unit noise. **Make sure the engine control is in the "OFF" position**.
Battery Charger:	- visual inspection of charger to verify operation. If equipped with a dial meter verify charge rate. If equipped with LEDs verify LEDs lit. **Red** LED only indicates battery discharged, charging at "Bulk" rate. **Red & Green** LED only indicates charger charging at "Absorption" rate. **Green** LED only indicates "Float" rate, battery is fully charged.
Battery Levels & Cables:	- make sure batteries are full of water, cables are tight and battery posts are clean.
Leaks: (Oil-Water-Fuel)	- check all hoses and connections for dripping, tighten hose clamps if needed.
Amps:	- when the unit is running with load, record the amp reading.
Volts:	- when the unit is running with load, record the volt reading.
Frequency:	- when the unit is running with load, record the hertz reading.
Oil Pressure:	- when the unit is running with load, record the oil pressure.
Water Temperature:	- when the unit is running with load, record the water temperature reading once stabilized.
BC Volts:	- battery charger DC voltage reading.
RTM:	- running time meter total should be recorded before each test - this will allow you to determine if the unit has run since the last exercise.
ATS:	- automatic transfer switch should be filled in as "OK" if the test performed a load transfer properly.
Mechanic:	- should be initialed by the person doing the test.

KATOLIGHT MODEL NUMBER DEFINITIONS

D	Diesel
60	60 kW
F	Brushless
G	1 Phase, 120/240 Volt
J	John Deere Engine
4	1800 RPM
CEP	Includes Ag. Accessory Package

L	LP Gas
50	50 kW
F	Brushless
P	3 Phase, 120/208 Volt
G	GM Engine
4	1800 RPM

N	Natural Gas
55	55 kW
F	Brushless
D	1 Phase, 120/240 Volt
N	Nissan Engine
4	1800 RPM

SED	Diesel
75	75 kW
F	Brushless
G	1 Phase, 120/240 Volt
J	John Deere Engine
4	1800 RPM

Model prefix denotes fuel:

* Optional – Will operate on Natural gas or Propane.

D – denotes diesel
G – denotes gasoline
L – denotes propane*
N – denotes natural gas*
SED – denotes enclosed "SP" diesel
SD – denotes OPU "SP" diesel
SENL – denotes enclosed "SP" natural gas or propane
SNL – denotes OPU "SP" natural gas or propane

First number group denotes kW capacity of generator.
First letter denotes type of generator:

F – Brushless rectifier type, direct connected, revolving field.
H – Revolving armature, self excited.
I – Induction generator.
X – Static excited, revolving field.
Y – Cranking excited, direct connected.

Second letter denotes revolving armature voltage and phase:

A – 115 volt, 1 phase, 2 wire
B – 277/480 volt, 1 phase
C – 240/480 volt, 1 phase (High Zig Zag)
D – 120/240 volt, 1 phase, 4 wire (Dedicated)
F – 115/230 volt, 1 phase, 3 wire (Revolving field type.)
G – 120/240 volt, 1 phase, 12 wire (Zig Zag) (Double Delta)
H – 1386/2400 volt, 3 phase (WYE)
J – 120/240 volt, 3 phase (High Delta)
K – 1905/3300 volt, 3 phase (WYE)
L – 7967/13,800 volt, 3 phase (WYE)
M – 3811/6600 volt, 3 phase (WYE)
N – 346/600 volt, 3 phase (WYE)
P – 120/208 volt, 3 phase (PAR WYE)
R – 277/480 volt, 3 phase (SER WYE)
S – 2400/4160 volt, 3 phase (WYE)
U – 4147/7200 volt, 3 phase (WYE)
T – 6351/11,000 volt, 3 phase (WYE)
Q – 2400 volt, 3 phase (Delta)
* – Multi-voltage, multi-phase, switchable

Third letter denotes engine manufacturer:

A – Catepiller
B – Briggs & Stratton
C – Continental / Chrysler
D – Allis Chalmers / Daewoo
E – Waukesha
F – Ford
G – General Motors
H – Hercules
I – Isuzu
J – John Deere
K – Deutz
L – Lister
M – Minneapolis Moline
N – Lombardini / Nissan
P – Perkins
Q – Two bearing generator, independent
R – Roiline / Rolls Royce
T – Hatz
U – Murphy
V – Volvo
W – Wisconsin
X – Detroit
Y – Mitsubishi
Z – Cummins

Last number/letter denotes number of poles, rpm and frequency:

3 – 2 poles, 3600 rpm, 60 cycle
4 – 4 poles, 1800 rpm, 60 cycle
5 – 4 poles, 1500 rpm, 50 cycle
6 – 6 poles, 1200 rpm, 60 cycle
7 – 2 poles, 3000 rpm, 50 cycle
I – 400 cycle

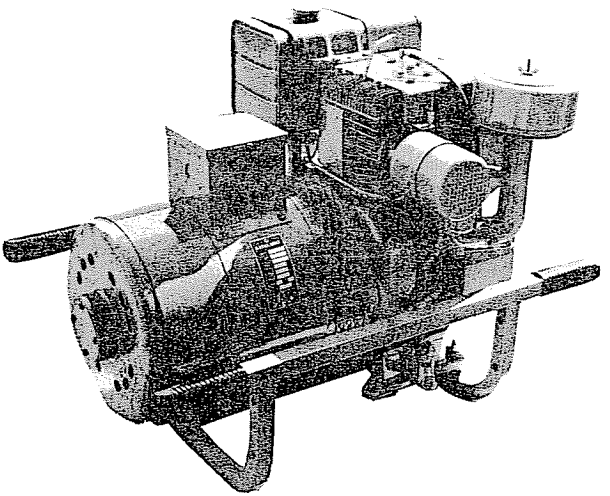
Katolight

POWER PLANTS

INSTRUCTION AND PARTS BOOK



9 models

from 750 to 5000 watts

Katolight Corporation

MANKATO, MINNESOTA

YOUR KATOLIGHT POWER PLANT

Guarenteed Insurance Against Power Failure

All Katolight Power Plants are manufactured to high standards of precision. Parts that require machining, grinding, or milling are made to even closer tolerances than required for good engineering, because we insist on a superior product.

Every phase of the manufacturing process is in the hands of skilled, specially trained electrical and mechanical workmen who build both high quality and long life into Katolight products.

Every model is precision engineered for maximum compactness and light weight to give a minimum of maintenance combined with the finest performance at lowest initial and operating costs.

Katolight generators are driven by such nationally known commercial engines as Briggs and Stratton, Wisconsin, Continental, Waukesha, General Motors, Cummins, and International, as well as other makes which have authorized service centers throughout the United States. These engines are familiar to the average mechanic making it unnecessary to depend upon the factory for maintenance and service.

All plants are shipped complete, ready for operation, with the addition of gasoline, oil and water in case of liquid-cooled units.

Controls are available on most models for emergency or standby units, which will start the plant automatically when the normal supply of electricity is interrupted. When the normal supply is restored, the plant stops automatically.

You are assured of AC power anywhere, anytime with a Katolight. power plant, manufactured in a size to meet every individual requirement from 750 watts to 400 KW, standby or continuous duty, portable or stationary installed.

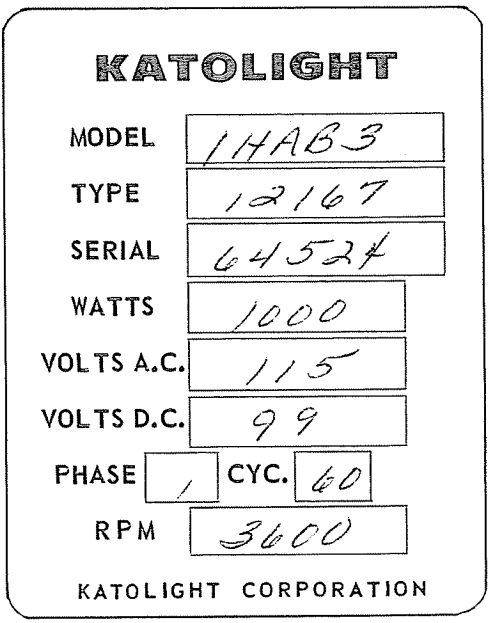
INSTRUCTIONS FOR ORDERING REPAIR PARTS

For parts or service, contact the distrbutor from whom you purchased this equipment or refer directly to Katolight Corporation.

To avoid errors or delay in filling your parts order, please furnish all information requested.

REFER TO THE NAMEPLATE ON YOUR PLANT.

1. Always give the MODEL & TYPE NO. and SERIAL NO.



For handy reference, copy YOUR Plant nameplate information in the spaces above.

2. Do not order by reference number or group number, use part number and description.

3. Give the part number, description and quantity needed of each item. If an old part cannot be identified, return the part prepaid to your distributor or Katolight Corp. Print your name and address plainly on the package. Write a letter to the same address stating the reason for returning the part.

4. State definite shipping instructions.

Any claim for loss or damage to your unit in transit should be filed promptly against the transportation company making the delivery. Shipments are complete unless the packing list indicates items are back ordered.

"Prices are purposely omitted from this Parts Catalog due to the confusion resulting from fluctuating costs, import duties, sales taxes, exchange rates, etc.

For Current parts prices, consult your Katolight Distributor or Katolight Corporation, Mankato, Minnesota.

This booklet pertains to 5 types of 1800 RPM and 4 types of 3600 RPM manual rope started air-cooled Katolight power plants from 750 watts to 5000 watts. Generators are of the revolving armature type, direct connected to the engine. The chart below indicates the 9 types and characteristics of each. Read both generator and engine instructions thoroughly prior to placing the unit in operation. When ordering spare or replacement parts, compare the nameplate data of your power plant with the corresponding parts list in this book.

Wattage Output	Voltage	Number of Lead Wires	RPM	Model Number	Type Number	Engine Make

Electric start, automatic transfer types are available in the same sizes listed above, as well as belt driven models, but are not covered in this book. A complete line of accessories are available for all models. Information and prices of power plants up to 400 Kilowatts will be sent on request.

-- WARRANTY --

This generator is warranted to produce its rated output as stamped on the nameplate when installed and operated in accordance with instructions.

It is warranted to be in good condition electrically and mechanically when leaving the factory.

It is warranted against electrical or mechanical defects in workmanship for a period of one year after shipment from the factory. Any parts found to be defective by factory inspectors after return to the factory, transportation charges prepaid, will be replaced or repaired free of charge. This does not include any component part or standard accessory such as meters, engines, relays, etc., made by other manufacturers, as these are subject to the warranties of those manufacturers.

Receiving Power Plant And Initial Precautions

This machine has been carefully tested and packed before leaving the factory. When unpacking, it should be thoroughly inspected to see if damage has occured in transit and to make certain that all parts, accessories, etc., are in proper condition and position. If damage is noted or material missing, notify the transportation company immediately and file a claim.

The windings and other internal components should be protected from damage when unpacking and handling. Under no circumstances should lifting hooks be attached to ventilating holes in the endbells as there is a possibility of damaging the internal parts.

All instructions and drawings contained in both this booklet and the engine manuel should be studied thoroughly prior to putting the unit in operation. Before any type of maintenance or adjustment is performed the machine should be shut down.

PROVIDE FUSE PROTECTION: Generator should be protected by fuses, fustats or fusetrons in accordance with the National Electrical Code and pertinent state codes. Engine governor should be checked periodically and adjusted according to engine manuel.

OBSERVE NAMEPLATE RATING: To avoid overheating and insulation breakdown, care should be taken that generator is not overloaded. Although generators are conservatively rated, the load should not exceed nameplate rating except for short periods of time.

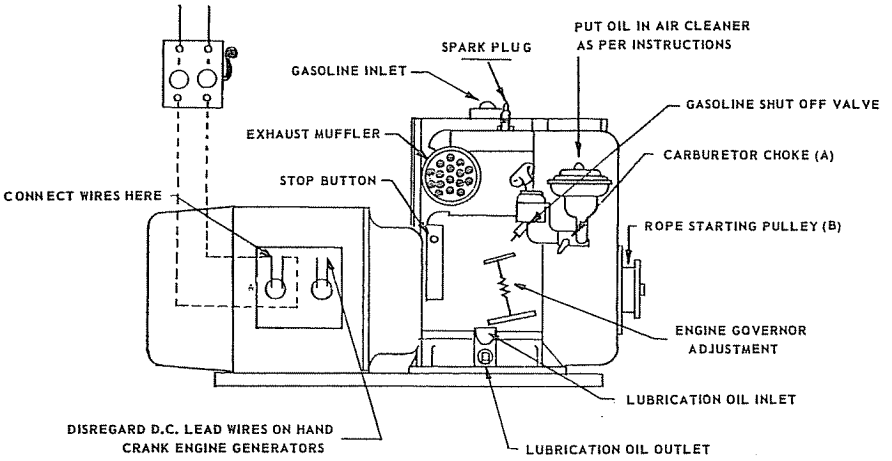
Cooling Air Supply

The successful operation of any electrical machine depends largely on its being installed under conditions that are favorable to its economical and efficient operation. A plentiful supply of clean, cool, fresh, dry air is necessary, with sufficient space on all sides of the machine to permit air to circulate freely. The power plant should be protected from moisture, escaping steam, dripping pipes, oil, acid, alcohol, chlorine or other corrosive gasses. Make certain that the ventilation holes in the generator frame are clean and free from foreign matter. Both engine and generator will heat if these precausions are not followed.

Precautions Prior To Starting

1. Before starting, remove the spark plug wires, ground them to the frame and rotate the armature to see that it turns freely.
2. Check brushes to see that they are seated firmly on the commutator and slip rings and that they move freely in their holders.
3. Check the engine in accordance with the engine manuel.
4. Make certain that generator and engine are securely bolted to base assembly.
5. Add fuel in tank - oil in reservior.

Starting Proceedure

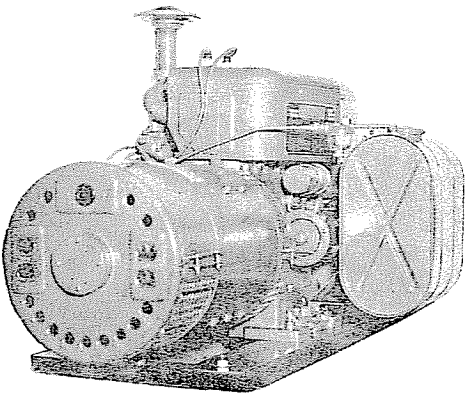


Open the gasoline shut off valve in fuel filter by turning the valve in a counter clockwise direction. Completely close the carburetor choke (A) by moving the choke adjustment lever in a clockwise direction. Wind the starter rope around the starter pulley (B) and pull the rope with a quick, steady pull to spin the fly wheel with choke fully closed to prime the engine. Then choke about 1/8 turn and repeat the operation. As the engine warms up, gradually open the choke valve.

TO STOP

To stop the plant equipped with a Briggs & Stratton engine, bring the ground strap into contact with the spark plug.

To stop the plant equipped with a Wisconsin engine, press the red button located on the breaker box.



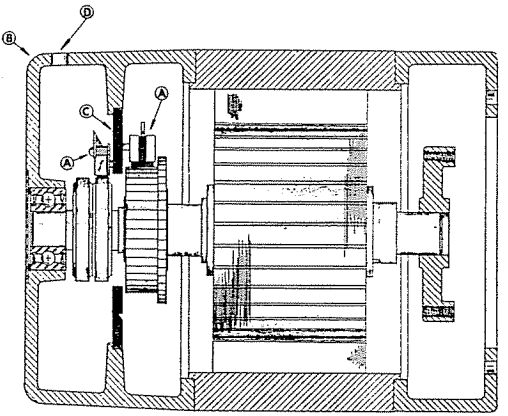
Wisconsin engine driven models are equipped with an engine starter. See engine manufacturers operating instructions.

Dissassembly And Assembly Procedures

Three types of engine generator adapters are used in assembling the generator to the engine.

However, when disassembling, the entire armature assembly can be removed from the commutator end of the generator on all models.

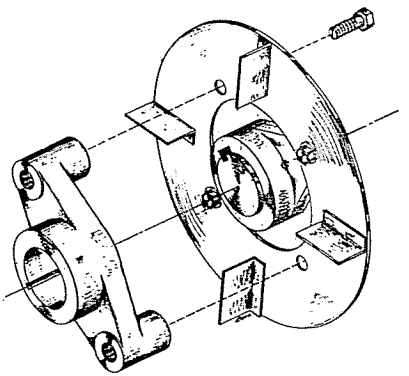
To remove armature (Drawing 1), first disconnect the DC field lead wires, then lift brushes (A) in their holders. Remove the entire endbell (B) and brush ring assembly (C). When removing, tap the endbell lightly outward at inspection holes (D) and the bearing will become free from the bearing race in the endbell and remain on the shaft.



Drawing 1

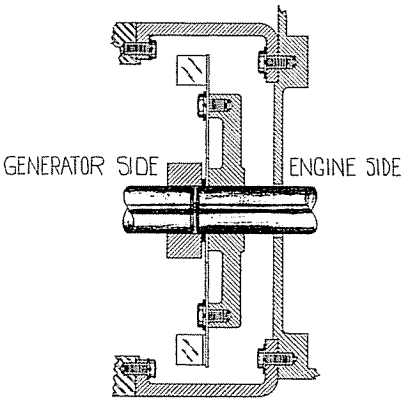
To remove the armature after the endbell has been removed, simply remove two bolts in the coupling assembly from the generator coupling half (Drawing 2). The fan and engine coupling half will remain on the engine shaft.

This type of coupling fan assembly provides flexibility and improves the operation of the unit and increases bearing life.

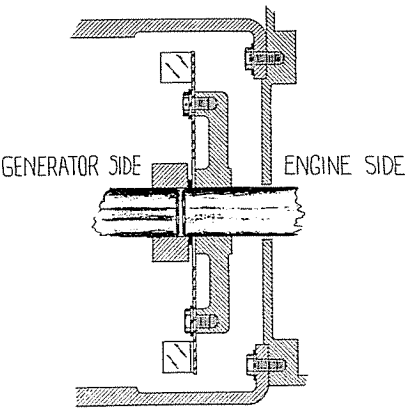


Drawing 2

On models with the adapter types shown in Drawings 3 and 4, the entire generator can be removed from the engine without removing the generator armature.



Drawing 3

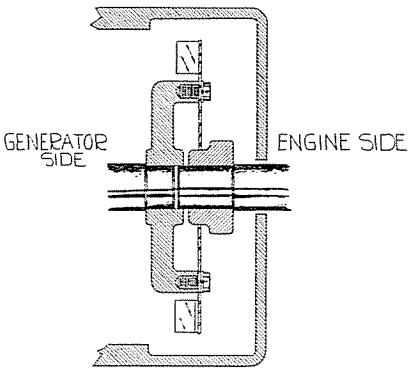


Drawing 4

With the type shown in Drawing 3, remove the bolts on the generator side of the adapter. The adapter will stay on the engine bell housing. Remove the two coupling bolts on the engine side and the fan will stay with the generator coupling half on the generator shaft.

With the type adapter shown in Drawing 4, the generator frame bolts directly to the engine. Remove the housing bolts and the two bolts from the engine coupling half. The fan will remain with the generator assembly.

The type of adapting provisions shown in Drawing 5 is used with all models up to 1000 watts which use the Briggs and Stratton 8FB engine.



Drawing 5

With these models, the generator frame cannot be removed from the engine until the armature has been removed. To remove armature, remove the two bolts from the generator coupling half, and the fan will stay on the engine shaft. When armature is removed, the generator frame can be removed by removing the bell housing bolts. A puller must be used to remove the engine coupling half from the engine shaft.

Reassembling Engine To Generator

Fit the generator to the engine and replace coupling bolts (A) and frame mounting bolts (D). Align the generator coupling half with the fan by turning the armature. Tighten frame bolts alternately and do not force any parts which may cause the shafts to become bent.

Reseat the brushes on the commutator and slip rings and align properly. Rotate the armature to see that it is working freely. Start the engine and operate briefly before replacing cover bands.

Bearing Replacement

The bearings used in this generator are of the facgory lubricated, grease sealed type and require no regreasing. The average bearing life is approximately 4,000 running hours.

When removing the bearing, pull it straight off the shaft, taking care not to tip the bearing which might scar the shaft.

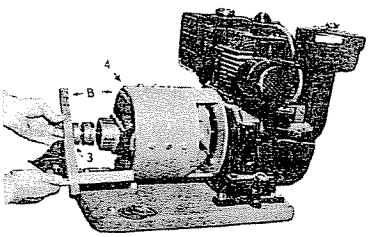
When fitting the new bearing, make certain that it is concentric with the shaft and tap the bearing onto the shaft with a rubber, fibre or leather hammer.

Make certain that the same spacing washers that are taken out or the equivilent are replaced when refitting the bearing into the bearing race.

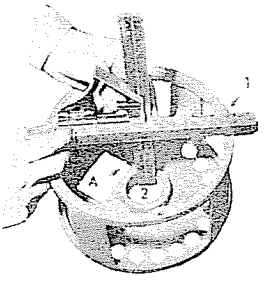
Allow from 1/16 to 1/32 inch end clearance. Too much end play will allow the collector rings and commutator to get out of line with the brushes. If there is too little end play, excessive pressure on the bearing will shorten its life.

To determine the end play, measure the depth of the alternator endbell (A) from the machined face (1) to the bearing seat (2). Place a straight edge flat on the machined face and measure the distance between the two points.

Next, measure the distance (B) from the outside edge of the bearing (3) to the machined lip of the alternator frame (4). Place a straight edge firmly against the outer bearing surface and measure with a rule at two opposite points to make certain that endbell depth is 1/16 to 1/32 inch greater to provide endplay. If measurement A (endbell depth) is less than 1/32 inch greater than distance B, remove spacers. If it is more than 1/16 inch, add spacers. The brush holder ring has been removed in order to show bearing race clearly.



A



B

Commutator And Slip Ring Care And Maintenance

Very often commutators and slip rings are remachined unneccesarily. Before attempting to remove the armature to remachine and undercut the commutator make certain that all necessary tests have been made to determine any other possible cause of voltage flucuations or other output deviations.

In many instances, replacing brushes and cleaning both brush holders and commutator will remedy DC excitation difficulties. Although some brush sparking may have caused small pits or black spots on the commutator surface there is usually not enough damage to cause poor commutation providing brushes are seated properly, holders cleaned, and commutator surface sanded properly.

When new brushes have been installed and sanded according to instructions, they should then be lifted in their holders and the commutator sanded. This can be done with a wood block covered with 00 sandpaper or with a commutator stone or burnisher. The latter are inexpensive items which can be ordered from the factory.

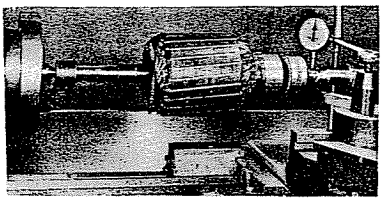
When resanding the commutator, hold the wood block or stone firmly and apply a small amount of even pressure. If the commutator is wider than the stone or block, move it back and forth vertically with firm even movements. In most cases, these repairs will restore the commutator for normal operation over a long period of time.

If commutator is badly pitted or out of round and it is necessary to remachine it, a competent machinist should be employed and extreme caution taken not to damage the shaft center when removing the armature. The shaft surface and the commutator and slip rings have been machined at the factory according to this shaft center. If it becomes damaged in anyway, and then the commutator or slip rings remachined, the commutator surface will not be concentric with the shaft and sparking and rapid wear of brushes will result when the machine is reassembled and operated. Serious damage to the entire generator can result.

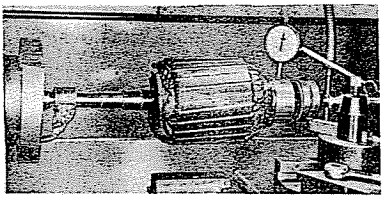
To determine if the shaft center has been damaged, the armature should be placed in a lathe and the shaft checked with a dial indicator as shown at A. The indicator should be placed at the position where the bearing rides or on the outer bearing surface if the bearing is in good repair.

If the shaft has been badly damaged and a new center resulted, use a steady rest to maintain alignment of the shaft surface and redrill a new true center prior to machining the slip rings or commutator.

When the remachining of the commutator or slip rings has been completed, their outer surface should be checked with a dial indicator as shown at B. Tollerance should be kept within 5/1000 of an inch.

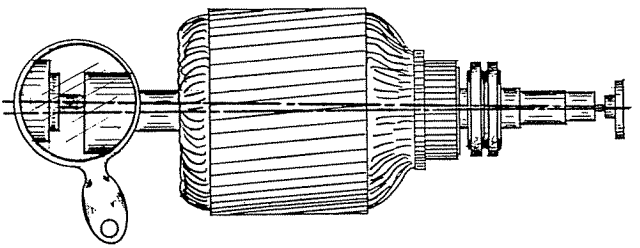


A

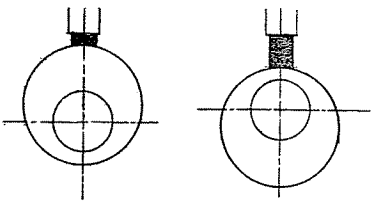


B

If the remachining is accomplished using the damaged center as shown at C, the commutator surface will be eccentric with the bearing and shaft. When put in operation, the brushes will be forced to move in their holders to conform to the eccentricity of the commutator as shown at D (shown slightly exagerated). The inner circle represents the shaft and the outer circle the commutator or slip rings.



Drawing C



Drawing D

When the remachining has been accomplished, it is necessary to undercut the mica segments.

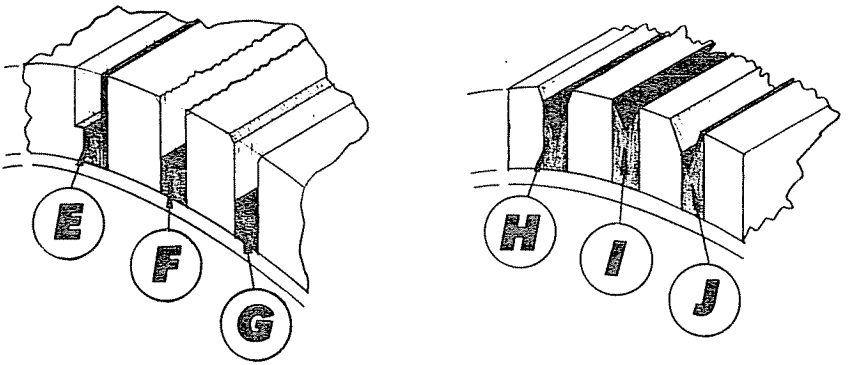
When a square undercutting tool is used it should be slightly wider than the mica and well centered so that a mica fin as shown at E is not left.

Rough edges as shown at F should be removed by beveling as shown at G.

When a "V" undercutting tool or a three cornered file is used, the tool should be slightly wider than the mica so as to get the bevel required as shown at H.

If the undercutting is not deep enough to make a bevel on the bars as shown at I, mica fins will be left.

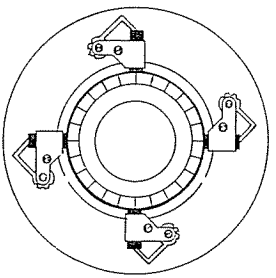
The tool should be well centered on the mica in order to avoid the mica fin as shown at J.



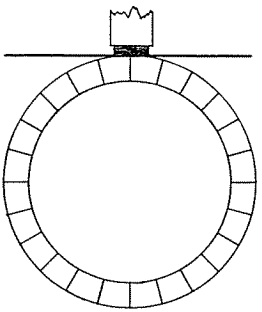
Replacing Brushes

All replacement brushes should be of the same grade, preferably of the same kind and type as originally supplied with the generator. To make certain the correct brushes are used, it is best to order them from the factory, giving generator model and type numbers as well as the part number of the brushes as listed on the parts list. It is wise to have an extra set of brushes on hand at all times.

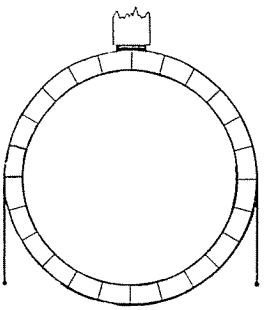
When installing new brushes, insert them only part way into the holders so that the brush tension arm will rest against the side of the brushes and prevent them from contacting the commutator and slip rings. The new brushes are now in a position to begin the fitting operation.



Drawing A



Drawing B



Drawing C

Brushes can be raised and locked in position away from the commutator or slip rings as shown in Drawing A.

A fine grade of sand paper can be wrapped around the commutator or slip rings and taped with the sand side toward the brushes. Then release the brushes against the sandpaper and rotate the sandpaper in the direction of operating rotation. Do not draw sandpaper across one brush at a time in a straight motion as shown at B.

The sandpaper should conform to the curvature of the commutator as shown at C.

Brush Holder Adjustments

Both the DC commutator brush holders and the AC slip ring brush holders of this generator are mounted on a single ring which fits into a machined recess in the end-bell and is secured with clamps. The DC commutator brushes are mounted on one side of the ring and the AC slip ring brushes on the other.

The brush holder ring has been set at the factory in the correct position to permit the commutator brushes to ride at the electrical neutral points of the commutator for best commutation. This position has been marked on both the endbell and the ring. If the brush ring assembly is removed, make certain that it is replaced in the position marked.

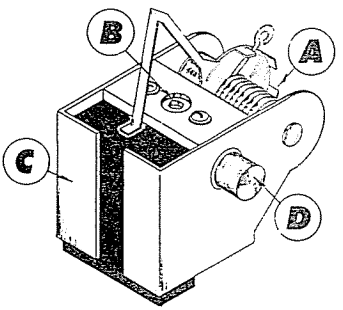
Spring pressure should be no greater than is needed to keep the brushes in constant contact with commutator and slip ring surface, approximately 2½ pounds per square inch.

Although there are provisions for brush spring tension adjustment on the holders, the tension should be increased only when absolutely necessary. The brush springs will retain their tension throughout the life of several sets of brushes providing that the tension is not destroyed by improper handling. Excessive heat will also destroy the tension of the steel wire.

Brush springs are inexpensive and replacements should be kept on hand.

The drawing shows the notches (A) in the brush holders which permits adjusting the spring tension.

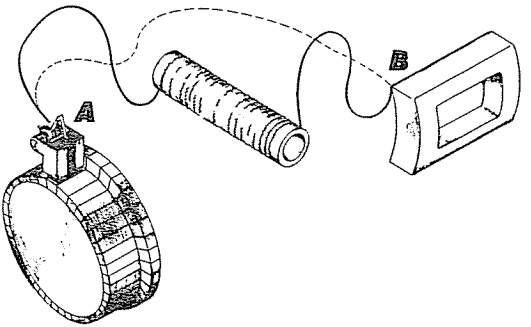
The brushes can be adjusted vertically to align them with the commutator and slip rings by merely loosening the set screw (B) and moving the brush holder (C) on the brush holder stud (D).



Voltage Regulation

The output voltage of this generator has been checked and adjusted during the testing period prior to shipment from the factory and will not require adjustment if operated in accordance with instructions.

A shunt field resistor (fixed type) of approximately 1.5 ohms has been placed between the field coil (A) and the DC commutator brusholder (B).



If the voltage drops below 110 or 220 volts, the resistor can be taken out and bypassed by connecting the brush lead directly to the field pole lead wire as shown by the broken line.

If voltage exceeds nameplate rating, a larger resistor can be ordered from the factory. A manually controlled rheostat can be ordered as an accessory.

Insulation Breakdown And Moisture Accumulation

If the generator has been subjected to extreme heat, moisture or other conditions which cause insulation breakdown and generator output voltage flucuates, a competent electrician should be employed to test for insulation breakdown with a megger.

A megger is a small hand operated generator which can be attached to any coil or lead wire. A low megger reading indicates a short circuit or low resistance due to insulation breakdown. Testing each coil with a megger will reveal the location of the short circuit. If the winding cannot be repaired, the factory should be contacted as replacement of coils or rewinding may be necessary.

Checking 60-Cycle Generator Frequency Without A Frequency Meter

The frequency of any rotating type AC generator is determined by the speed at which the rotating portion operates. A four-pole generator, for example, will produce a frequency of exactly 60 cycles per second if operated at a speed of 1800 revolutions per minute. Any speed variation will cause a frequency variation. For this reason, it is very important that the engine governor be adjusted properly. Detailed engine governor instructions are given in the engine instruction book.

Frequency meters can be ordered as optional equipment for these small air cooled engine generators as well as for larger units. If a frequency meter is not available the frequency can be determined and adjusted easily, using only a standard 60 cycle electric house clock as an indicator.

Plug the clock cord cap into the generator output receptacle and adjust the engine governor until the movement of the second hand of the houseclock is exactly the same as the second hand of an accurate watch.

See the engine manual for governor adjustment procedure.

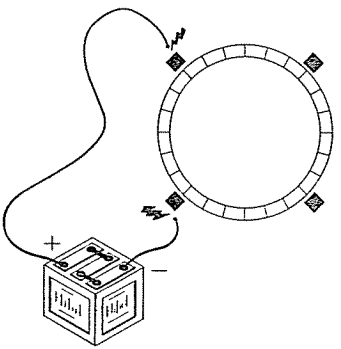
This adjustment sohould be made with an average load on the generator.

Restoring Residual Magnetism

The direct current (DC) necessary to excite the magnetic field poles of this AC generator is created by a separate DC winding which is mounted on top of the AC windings in the generator armature. The DC from this excitation winding is "picked off" from the commutator by the DC brushes and fed to the stationary field coils in the magnetic field frame.

If a generator is not operated for a long period of time, the residual magnetism in the field poles may become so weak that current will not be produced when the generator operates. The residual may also be neutralized if the generator is temporarily overloaded when a large motor starts up or if a motor is stalled, causing the motor to overload the generator.

To restore the small amount of residual magnetism necessary to begin the field pole buildup, connect a 6 or 12 volt DC storage battery into the shunt field circuit, making certain that the battery is in series with the shunt field. This can be accomplished easily by first raising the DC commutator brushes to take the armature out of the circuit, eliminating unnecessary heavy current drain through the armature, and then connecting the battery positive and negative terminals to opposite brushes.



The battery can also be connected into the shunt field in this manner to supply booster current to the field poles while the generator is in operation and heavily loaded. In this event, the brushes must be in normal position, riding on the commutator.

Portable Service

Carrying handles and two-wheel dollies are available as accessories to all Katolight small power plants for ease in moving them about in construction areas or for a variety of home and farm uses.

When the engine has been started and "warmed up," merely plug the light or power tool cord caps into the generator 115 or 230 volt output receptacles as required.

A deep freeze or other home appliance can be operated directly from the plant without going through an existing wiring system.

Adapting Katolight Power Plants To Standby Service

There are three prime considerations when making plans for any standby installation of a relatively permanent nature. They are: (1) The size and nature of the emergency load desired; (2) The powerplant must be adapted to the existing wiring system, and (3) Any standby installation and transfer method from the central power line to the power plant must conform to pertinent electrical codes.

Determining The Emergency Load

The size of the powerplant necessary (wattage output) for a given load, or the amount of load that can be applied to a generator can be determined by adding the wattage requirements for each motor, appliance or light which will be operated by the standby plant during a power failure. The total should not exceed the nameplate rating of the generator.

Resistance loads, such as lights, flat iron, toaster, hot water heater, etc., are usually marked as to maximum watts consumed when in use.

Most electric motors require approximately three times as much current when starting as when running. When computing motor load it is only necessary to include the starting current of the largest motor and this added to the running current of all other motors and other load factors determines the size of generator required.

If the use of a very small plant is desired, it will be necessary to eliminate the use of all lights and appliances which are not essential.

APPROXIMATE WATTS REQUIRED FOR ELECTRIC APPLIANCES

APPLIANCE	WATTS (Starting watts for motors not shown)
Lamp Bulbs	25-150
Radio	40-200
Television	150-300
Vacumn Cleaner	200-250
Automatic washer	-400
Air Conditioner (¾ ton)	-1,250
Refrigerator	-325
Food Freezer	-300
Furnace (Oil)	-700
Deep Well Pump	-2,000
Electric Range	600-10,000
Hot Plate (per burner)	600-1,200
Toaster	600-1,130
Water Heater	1,500-5,000
Glow Heater	600-1,200
Heating Pad	40-80
Sun Lamp	250-1,000
Flat Iron	600-1,200
Laundry Dryer	-4,750
Electric Heat System	5,000-20,000

APPROXIMATE WATTS REQUIRED FOR MOTORS

MOTOR SIZE	STARTING WATTS	RUNNING WATTS
1/9 HP	500	250
1/6 HP	750	300
1/3 HP	1000	400
1/2 HP	1200	550
3/4 HP	2000	800
1 HP	2500	1000
1 1/2 HP	3750	1500
2 HP	5000	2000

----------		----------		----------		----------	

Always check the wattage requirements shown on the lamp or appliance. Check the motor nameplate of all appliances which have motors and allow for additional controls and starting load. For example, an oil furnace may include two 1/6 HP motors as well as a transformer and other control equipment.

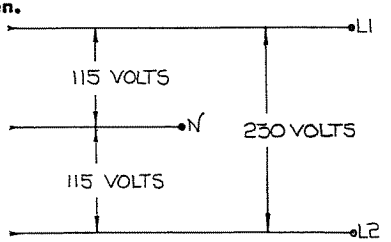
The chart will serve as a guide in determining the emergency load and the size of the generator required. Katolight power plants have ample overload capacity and operate efficiently even at small loads.

Two And Three Wire Systems

As shown on the chart at the introduction of this book, power plants are available in either two or three wire design. There are advantages to either service. Some of the considerations are explored in the following paragraphs.

To simplify drawings, some electrical symbols have been used as follows: A line wire or "leg" which carries 115 volt alternating current (AC) is shown as L1 or L2. A neutral wire, which serves as a ground wire, is referred to as N. There is no voltage on the neutral wire unless the ground is broken.

The average home today has a three wire service when served by central station power. With 3 wire service, it is possible to get either 115 or 230 volt AC output. To accomplish this, an appliance is connected between L1 and L2 for 230 volt service and between either L2 and N or L1 and N for 115 volt service (drawing A).



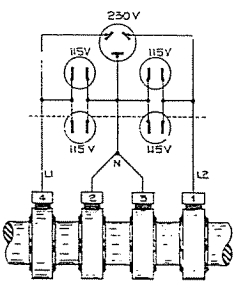
Drawing A

Note: All equipment marked 110 volt can also be supplied from 115 volt circuits. Equipment marked 220 volts can be supplied from 230 volt circuits.

Three Wire Generators

The receptacles of a 3 wire generator are connected to supply both 115 and 230 volt output. With this type connection, full load can be drawn from the 230 volt outlet. The 115 volt load must be balanced on both legs, however, if maximum 115 volt service is to be obtained. For example, if the nameplate rating is 5000 watts, the entire 5000 watts can be drawn from the 230 volt receptacle, but only up to 2500 watts can be drawn from each of the 115 volt receptacle groupings. To draw 5000 watts, 115 volt load from this generator as connected at the factory, the 115 volt load can not exceed 2500 watts on each leg (drawing B).

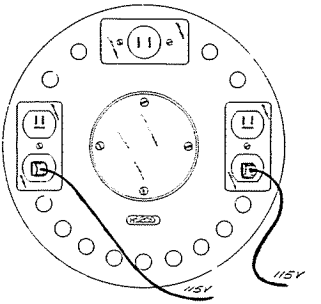
Each of the two 115 volt groupings can be connected to separate circuits within the distribution box. In this way, half of the generator capacity will be available to each circuit. A temporary arrangement can be made as shown in drawing C.



Drawing B

Katolight Service - Master Repair Manual - Page 137

For permanent standby installation with generator 115 volt output divided equally between two circuits, connect one or more circuits to L1 and N and another circuit grouping to L2 and N at a point shown by the broken line in drawing B.



Drawing C

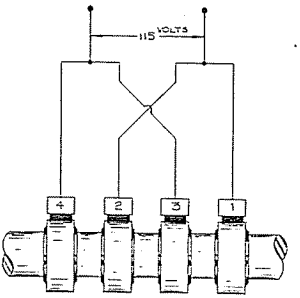
Because these 3 wire generators are supplied with 4 slip rings, it is possible to reconnect the 4 lead wires from the slip rings to draw maximum 115 volt output from a single circuit.

Each of the 4 slip ring wires are marked with a number at the factory. Starting at the armature and going toward the bearing, the numbers are 4, 2, 3, and 1.

To reconnect, the two wires which form the neutral (2 and 3) must be broken and wire 4 (L1) connected to wire 3 and wire 1 (L2) connected to wire 2 (drawing D).

The connection to the fused distribution box through a double pole selector switch, for this type service, is the same as shown for two wire generators (drawing H).

To fused distribution circuits through a double pole, double throw selector switch.

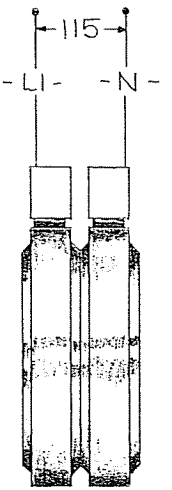


Drawing D

With this arrangement, the generator can be connected to one or more circuits within the distribution panel and maximum 115 volt capacity can be drawn through each fused circuit.

Two Wire Generators

Two wire generators have only two slip rings and two lead wires (L1 and N). It is impossible to obtain 230 volt service from these units. When connected to the distribution panel, the entire 115 volt output is available on any circuit, making it unnecessary to balance the load (drawing E). A two wire generator is very satisfactory to install where existing wiring systems are only two wire or where only 115 volt service is required.

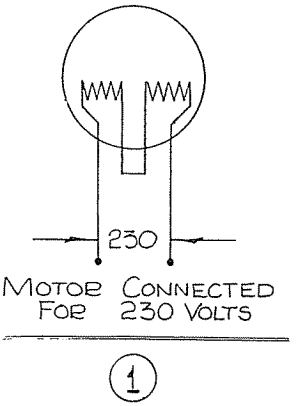


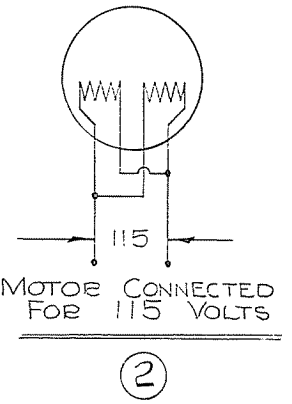
Drawing E

If it is essential that a 230 volt appliance be operated during an emergency, and it is impossible to operate the appliance from 115 volt service, a three wire standby generator must be installed.

If the only 230 volt requirement is a 230 volt, single phase electric motor, it can usually be reconnected for two wire, 115 volt service temporarily as shown in drawings F1 and F2.

Most 230 volt single phase motors can be operated at 115 volts if reconnected in the following manner.





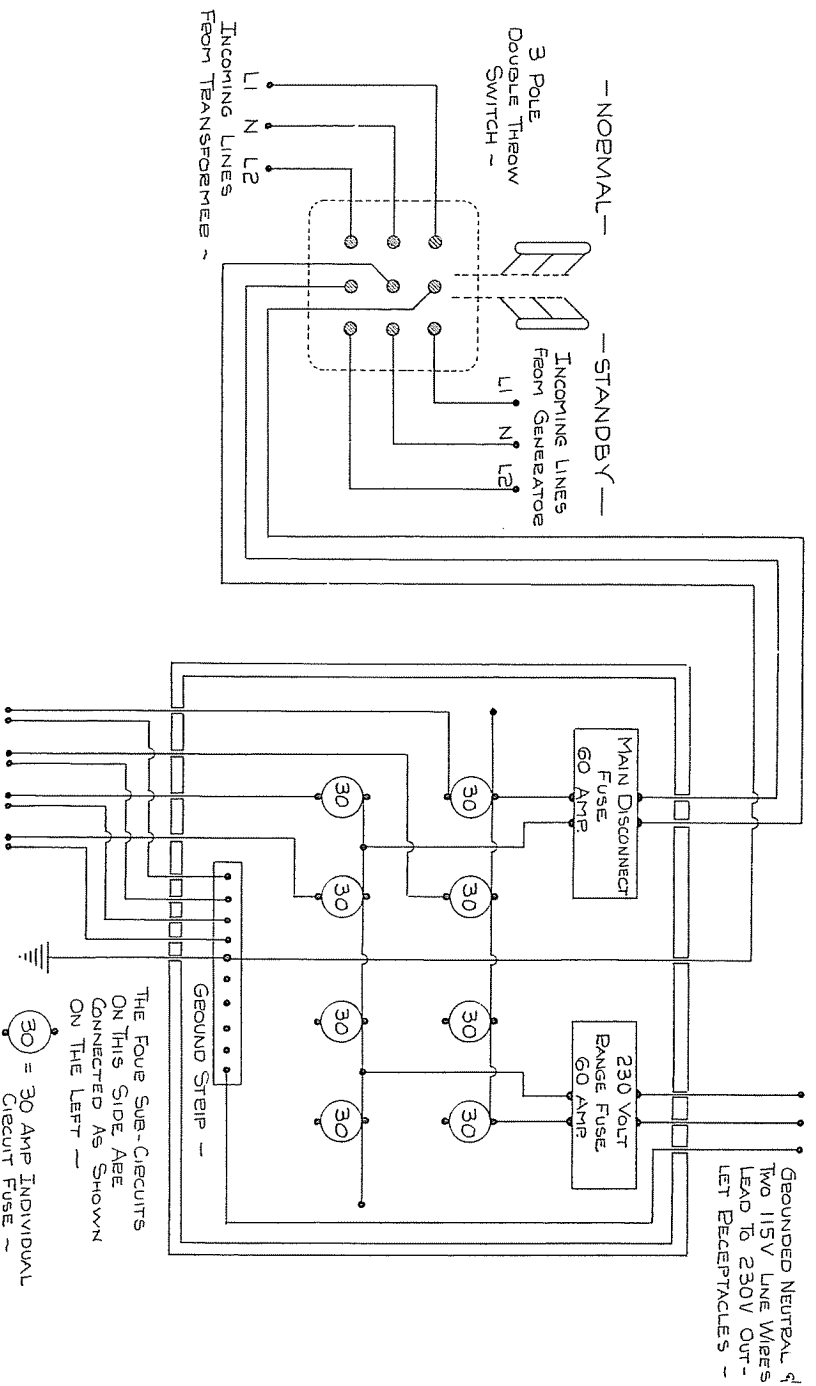
Drawing F

If large heating units must be operated during an emergency, such as electric ranges or heaters, or if the user does not wish to be inconvenienced by minimizing the load, a larger three wire power plant should be installed. One or two range burners, for example, could possibly draw all of the current from a 2500 or 3500 plant.

Methods Of Transfer

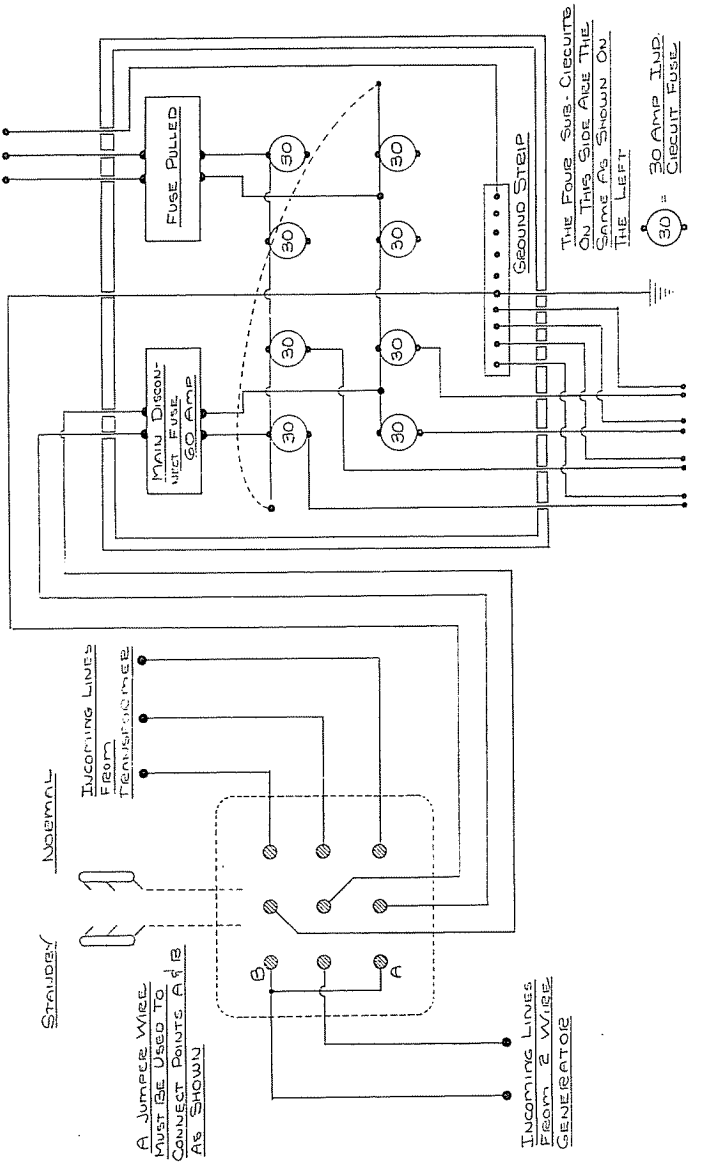
There are many different ways of connecting the transfer from normal power supply to the standby generator. Systems can be devised for the generator to handle the entire load or for it to handle only one or two preselected circuits, according to emergency needs. If the generator is connected to all distribution circuits, the emergency load must be more closely controlled at the appliances themselves.

Wiring codes vary from state to state and even within a given locality served by different power companies, so it is impossible to recommend any definite method of transfer. The examples given here are general and are intended to serve as suggestions only.



-NORMAL-
-STANDBY-
3 POLE DOUBLE THROW SWITCH -
INCOMING LINES FROM TRANSFORMER -
L1 N L2
INCOMING LINES FROM GENERATOR
L1 N L2
MAIN DISCONNECT FUSE 60 AMP.
230 VOLT RANGE FUSE 60 AMP.
GROUNDED NEUTRAL & TWO 115V LINE WIRES LEAD TO 230V OUTLET RECEPTACLES -
GROUND STRIP -
THE FOUR SUB-CIRCUITS ON THIS SIDE ARE CONNECTED AS SHOWN ON THE LEFT -
30 = 30 AMP INDIVIDUAL CIRCUIT FUSE -

Drawing G



Drawing H

If double throw switch is not used, it is possible to connect the generator leads direct to distribution box by attaching the neutral wire to the ground strip and L1 and L2 to the circuit leads. Main disconnect fuse must be pulled in this case. If this is done, a jumper wire must be placed between the two sub terminals as shown by dotted line from point C to point D.

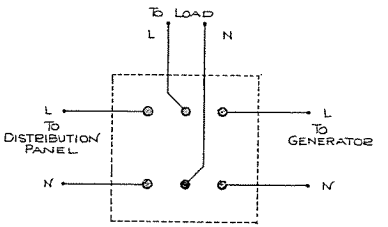
230 volt fuse should be pulled when 2 wire standby service is used. 230 volt motors will not operate but will not be harmed if fuse is not pulled, however, providing jumper wire is in place.

WHEN INSTALLING ANY TRANSFER SYSTEM, A COMPETENT LOCAL ELECTRICIAN, FAMILIAR WITH ALL EXISTING FEDERAL, STATE AND LOCAL CODES SHOULD BE EMPLOYED.

OF PRIME CONSIDERATION IN DESIGNING ANY STANDBY SYSTEM IS THAT PROVISIONS BE MADE TO PREVENT THE GENERATOR FROM FEEDING BACK INTO THE COMMERCIAL LINES SHOULD CURRENT FROM THE STANDBY PLANT BE IN CIRCUIT WITH THE MAIN INPUT LINE, THE VOLTAGE STEP DOWN TRANSFORMER WILL ACT AS A STEP UP TRANSFORMER, PLACING A HIGH VOLTAGE ON THE HIGHLINES. A LINE WORKER, MAKING REPAIRS ON THE LINES, COULD BE KILLED INSTANTLY.

Drawing G shows one possible method of permanently installing a 3 wire generator into the entire wiring system. Drawing H basically illustrates a method of connecting a two wire standby generator into a 3 wire wiring system. Drawing I shows how a double throw switch can be installed directly between the load and the generator.

With two wire service, a two-pole, double throw switch can be connected between one or more of the distribution circuits and the load, as shown in figure H. With this arrangement, the line from the power station remains closed through the distribution panel and up to the switch. When the switch is closed between the generator and the load, the circuit from load to the normal supply is broken and there is no danger of feed back from the generator into the lines.



Drawing I

Balancing Load On Three Wire Distributing System

When the commercial lines are operating normally, the 3 wire system is supplied from a secondary of a transformer. When the load on each leg is approximately the same, the current is zero in the neutral wire. No current flows on the neutral.

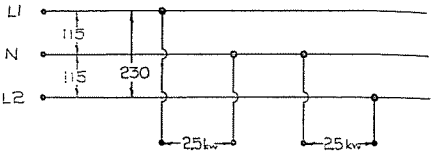
If this load were placed on a two wire system, the current drain would be 40 ampres on the wire from transformer to fused circuit breakdown box, requiring wire of at least twice the size as with three wire service. This, and the fact that many homes which do not require 230 volt service when initial wiring is done may require it later, are reasons why most commercial wiring codes now call for 3 wire service.

Farm and residential distribution transformers are usually of ample capacity to take care of the customers unbalanced load requirements.

The distribution circuits in the home are equally distributed across the 3 wire system. If there are eight circuits, there will be four circuits on each leg. This is illustrated in drawing G.

Because of the output limitations of small standby plants, the necessity of balancing the load on each leg is much greater. The following illustrations will illustrate more clearly the necessity of balancing a three wire generator and explain why there is no problem of overloading a circuit when a two wire generator is used providing nameplate full load rating is observed and proper sized wire is used.

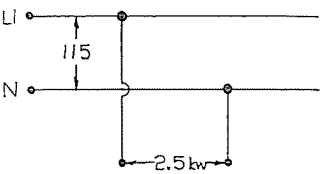
If a 115 volt motor requires 2500 watts for starting, it is necessary to have a 5000 watt 3 wire generator as the capacity on each leg is 2500 watts. A 2500 watt 2 wire generator could supply this motor if there is no additional load. See drawings I and J.



Line from 115/230 volt, 3 wire, 5000 watt generator fully loaded and balanced with 115 volt load. There is no 230 volt load.

Drawing J

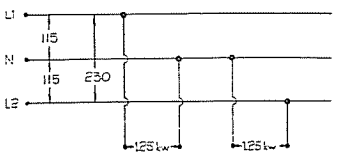
A 2500 watt 3 wire generator, as connected at the factory could not supply the motor as there is only 1250 watts on each leg (drawing K).



Line from 115 volt, 2 wire, 2500 watt generator. There is no problem of balancing.

Drawing K

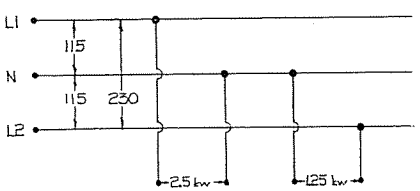
When dividing the emergency load over circuits supplied by each of the two legs of a three wire generator, a balanced load on each leg must be determined. For example, if circuits 1 through 4 in the distribution panel are supplied by L1 and circuits 5 through 8 by L2, the emergency load should be distributed evenly to take advantage of the full capacity of the generator (drawing L).



Line from a 115/230 volt, 3 wire, 2500 watt generator fully loaded and balanced with 115 volt load. There is no 230 volt load.

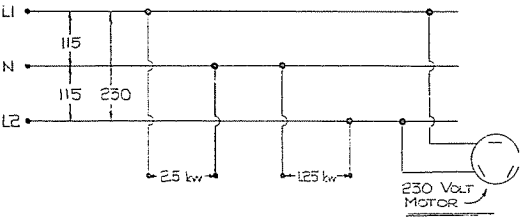
Drawing L

When a 230 volt load is placed on the 230 volt circuits of a 3 wire generator, half of that load will be on L1 and half on L2. If either L1 or L2, 115 volt circuit groupings are fully loaded, any additional 230 volt load will overload the generator (drawing M).



Line from a 115/230 volt, 3 wire, 5000 watt generator. Load is unbalanced. Any additional load must be added between L2 and N.

Drawing M



Line from a 115/230 volt, 3 wire generator. Line 1 is fully loaded. Line 2 is partially loaded. If any 230 volt load is applied, L1 will be overloaded.

Drawing N

TROUBLE SHOOTING PROCEDURES

AC GENERATORS

After a generator has been in service for many running hours, or if regular maintenance and checking is neglected, repairs and replacement of component parts may be necessary, as with any other machine. Almost all troubles that may occur are listed in the following pages, together with the probable causes and remedies for each. All instructions do not apply to both revolving field and revolving armature generators.

Instructions concerning excitation are intended to be general enough to include separate rotating DC exciter, excitation winding on armature or static excitation of magnetic field poles of AC generators.

VOLTAGE DEVIATIONS

The generator output voltage should be kept as close as possible to the voltage shown on the generator nameplate. High voltage, low voltage and fluctuating voltage (voltage hunting) may cause serious damage to the generator as well as the equipment operating from the generator current.

NO VOLTAGE

Cause	Remedy
Poor brush connection (either commutator or slip ring brushes.)	Clean and adjust or replace brushes. Repair commutator and slip rings if necessary. Make certain that brushes do not bind in brush holders and that brush wires are connected properly. See additional information concerning maintenance of brushes, commutator and slip rings.
Loss of residual magnetism in field poles, by long inactivity, lightning striking system, overload or short circuit.	Raise DC brushes and contact positive and negative brushes to a 6 or 12 volt storage battery momentarily to produce polarity.
Excitation (DC) leads open or shorted.	Check with continuity lamp or ohm meter. Replace leads if necessary.
Too much resistance in field rheostat or resistor.	Reduce resistance of rheostat or remove or replace resistor.
Open field circuit in field coils, field rheostat switch or fuse.	A DC test lamp should be used to trace the open circuit. If open circuit is indicated, repair or replace defective part.

Cause	Remedy
Short circuit in line or load.	Check for short in load by removing each individual motor or appliance from the line by switching it to off. Check the line by disconnecting the generator from the line at the generator terminal box.
Open armature windings due to commutator throwing solder from riser because of excessive heating.	Commutator must be resoldered, turned and undercut. See commutator maintenance instructions.
Coils shorted or open.	Check for open circuit with a continuity lamp and for short circuit with an ohm meter. Replace coil if necessary.
Shorted slip rings.	Disconnect lead wires and check slip ring insulation with a megger. Repair or replace slip ring assembly if defective.
Defective meters.	Repair or replace or bypass meters.
Open ammeter shunt or filter choke.	Check for open circuit with a continuity lamp. Replace or repair defective part.
Internal moisture, indicated by low resistance readings on megger.	Dry out the windings. Machines of small capacity may be dried out by putting them into a hot, dry room or by heating them up moderately from an outside source. Large machines should be run several hours with full load current with generator lead wires short circuited. To do this, lower the AC voltage by adjusting the field rheostat to maximum resistance so that the stator coils are not overloaded.

LOW VOLTAGE

Cause	Remedy
Excessive load.	Reduce load. With 3 wire, single phase and 4 wire, three phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.

Cause	Remedy
Low Speed: 1. Belt slipping. 2. Defective governor. 3. Defective carburetor. 4. Defective bearing. 5. Excessive load.	1. Tighten belt. 2. Adjust, repair or replace governor. 3. Adjust, repair or replace carburetor. 4. Replace bearing. 5. Reduce load.
Insufficient excitation.	Decrease field resistance by adjusting rheostat or removing resistor or adjusting resistor jumper wire.
Line loss.	Increase size of line wire.
High resistance connections. Connections will be warm or hot.	Make better connections electrically and mechanically.
Reversed field coil or armature coil connection.	Connect properly.
Shorted field.	Test field coils for possible short by checking resistance with an ohm meter or resistance bridge. Replace defective coil if necessary.
Brushes dirty or not properly seated.	Clean or replace brushes and reseat.
Slip rings or commutator dirty or in need of repair.	Clean or repair as necessary. See additional information concerning care and repair of slip rings and commutator.
Low power factor.	Reduce inductive (motor) load. Some AC motors draw approximately the same current regardless of load. Do not use motors of larger horse power rating than is necessary to carry the mechanical load.
Weak field due to operating in warm temperature.	Improve the ventilation if generator is housed indoors. Field current can be increased providing the generator temperature does not exceed temperature rating stamped on the nameplate.

FLUCTUATING VOLTAGE

(May be indicated by flickering lights)

Cause	Remedy
Irregular speed of prime mover (engine or electric motor).	Check and adjust governing device and carburetor if engine driven.
Voltage regulator not operating properly (regulator may be automatic or manual adjust. Many generators are equipped with a rheostat or a fixed resistor only.	Regulator may be bypassed. If generator is operated without regulator, output voltage should be checked to make certain that it is approximately the same as stamped on the generator nameplate.
Fluctuating load.	Stabilize load. The addition of a lamp load (resistance load) may compensate partially for load changes caused by intermittent motor operation.
Poor brush contact.	Clean and adjust or replace brushes. See additional information concerning care of brushes, commutator and slip rings.
Loose terminal or load connections.	Make better connections mechanically and electrically.
Generator overloaded.	Reduce load.
Slip rings or commutator out of round or pitted.	Turn rings or commutator on a lathe concentric with bearings. See slip ring and commutator maintenance instructions.
DC excitation voltage fluctuating.	Trace DC excitation through brushes, commutator and field coils and make repairs as necessary.
Shorted field coil.	Test field coils for possible short by checking resistance with an ohm meter or resistance bridge. Replace defective coil if necessary.
Defective bearing causing uneven air gap.	Replace worn bearing.

HIGH VOLTAGE

Cause	Remedy
Improper field adjustment (excessive magnetic field strength.)	Increase excitation field resistance by adjusting rheostat or adding a fixed field resistor.
Excessive speed.	Adjust governor and carburetor if engine driven, making certain generator operates at rated speed as stamped on the generator nameplate.
Faulty voltage regulator operation.	Try operating without regulator or replace regulator.
Operating in sub-zero temperatures.	Increase field resistance.

BRUSH SPARKING

Cause	Remedy
Commutator defective: 1. Outer surface not concentric with shaft. 2. High mica bars. 3. Surface pitted or rough.	Machine and undercut commutator according to specific instructions in this book.
Slip rings defective: 1. Surface not concentric to shaft. 2. Surface pitted or rough. 3. Slip ring insulation defective.	Repair slip rings according to maintenance instructions in this book, or replace.
Brushes not in commutating plane.	Brush holder rings are set at the factory and marked in a position so that the brushes ride at electrical neutral points on the commutator. If brush ring is removed for any reason it should be replaced in the original position as marked.
Loose brush holder.	Realign and tighten.
Lack of brush pressure.	Adjust or replace brush tension spring.

Cause	Remedy
Improper grade of brushes.	If time permits, order brushes from the factory by part number. It is best to keep an extra set of brushes on hand and replace old brushes when approximately two-thirds worn.
Dirty commutator or slip rings.	Sand lightly with 00 sandpaper.
Generator overloaded.	Check ammeter readings and compare with nameplate rating. With 3 wire, single phase and 4 wire, three phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
Open armature	Check for open circuit with a continuity lamp. Repair or replace armature if necessary.
Grounded, open or shorted field winding.	Check for open circuit with a continuity lamp and for short circuit with an ohm meter. Replace coil if necessary.

OVERHEATING

Most machines are designed to withstand a temperature rise of 50°C (see nameplate rating) 50 degrees Centigrade equals 122 degrees Fahrenheit.

Cause	Remedy
Generator overloaded.	Reduce load. (Check ammeter readings and compare with nameplate rating.)
Clogged ventilating screens.	Clean air passages.
High room temperature.	Improve ventilation.
Insufficient circulation.	Provide cross-ventilation.
Operating with excessive voltage.	Check voltage drop in distribution lines and connections and adjust voltage as described in voltage deviation instructions.

Cause	Remedy
Low power factor.	Reduce inductive load (motors), or install power factor improvement capacitors.
Unbalanced load on 3 wire, single phase or 4 wire, 3 phase generators.	The load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
Motors operating off generator not designed for generator frequency and voltage.	Motors operating from generator must be of the same frequency and voltage as stamped on the generator nameplate.
Generator coils or windings shorted or grounded.	Test field coils for possible short by checking resistance with an ohm meter or resistance bridge. Replace defective coil if necessary.
Excessive brush pressure.	Adjust pressure or replace brush tension springs.
Coupling misaligned or belt too tight.	Align or adjust.
Bent shaft.	Straighten or replace.
Endbells out of position.	Align endbells so that the air gap between the rotating part and the stationary part is equal at all points.
Dry bearing.	Replace bearing.

MECHANICAL NOISE

Cause	Remedy
Dry or defective bearing.	Replace bearing.
Rotor rubbing on stator.	Replace worn bearings.
Loose lamination.	Tighten bolts, dip in varnish, and bake.
Loose or misaligned coupling.	Tighten or align.

FREQUENCY DEVIATION

Cause	Remedy
Generator speed above or below nameplate rating orfluctuating.	Adjust governor.

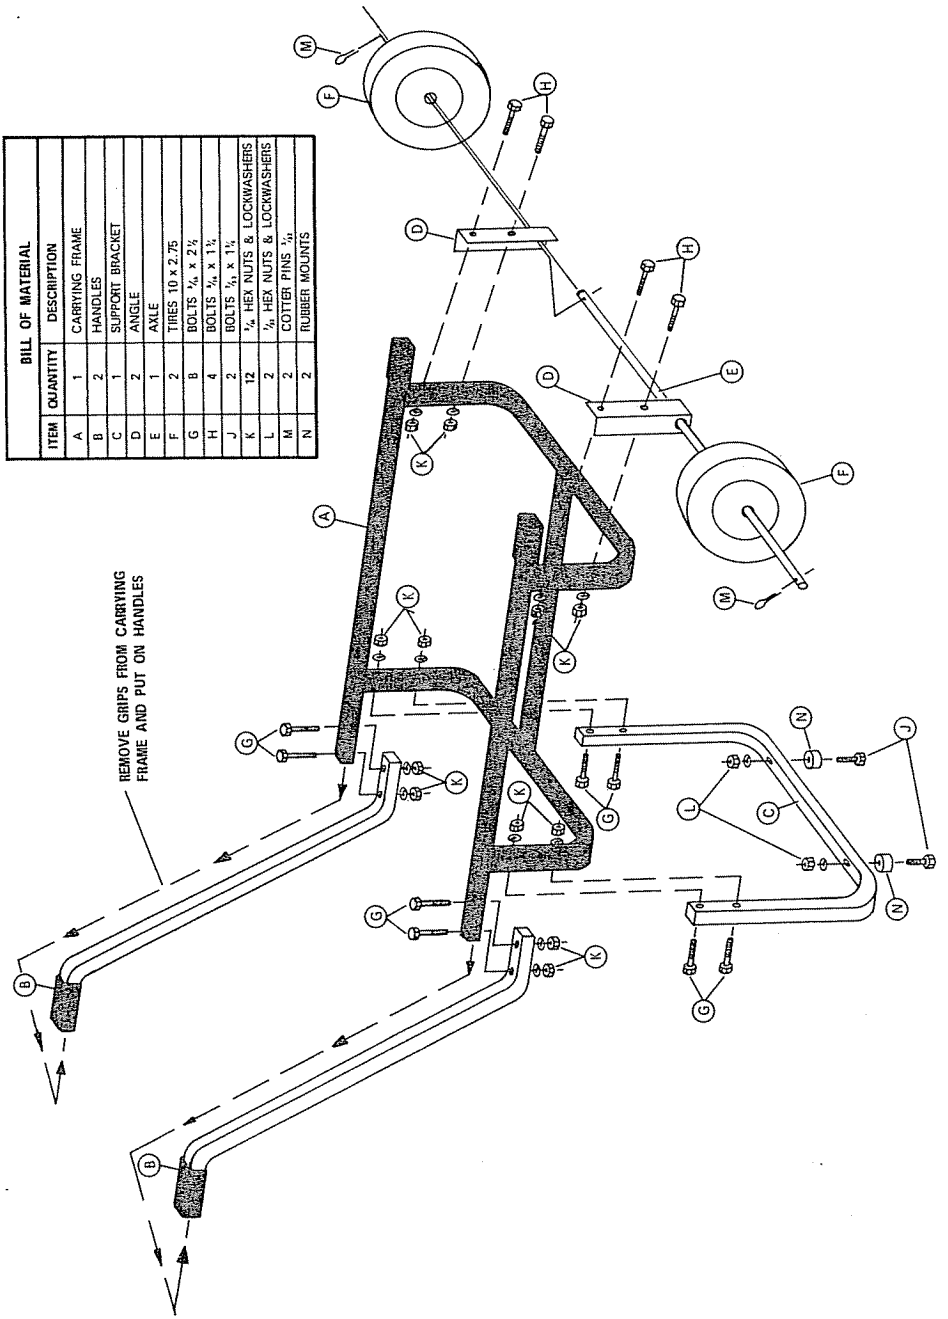
RADIO INTERFERENCE

Cause	Remedy
Radio frequency interference generated by sparking brushes.	Connect .5 mfd. capacitors from all ungrounded brushes to the frame. Voltage rating of the capacitors should be at least twice the rated voltage of the circuit to which they are connected.
Radio interference caused by leakage of static charge from generator shaft.	Install shaft grounding brush assembly, purchased from the factory.
Radio interference caused by electrical system of prime mover (engine or electric motor.)	Suppress radio interference. Consult a competent radio repair man or electrician.

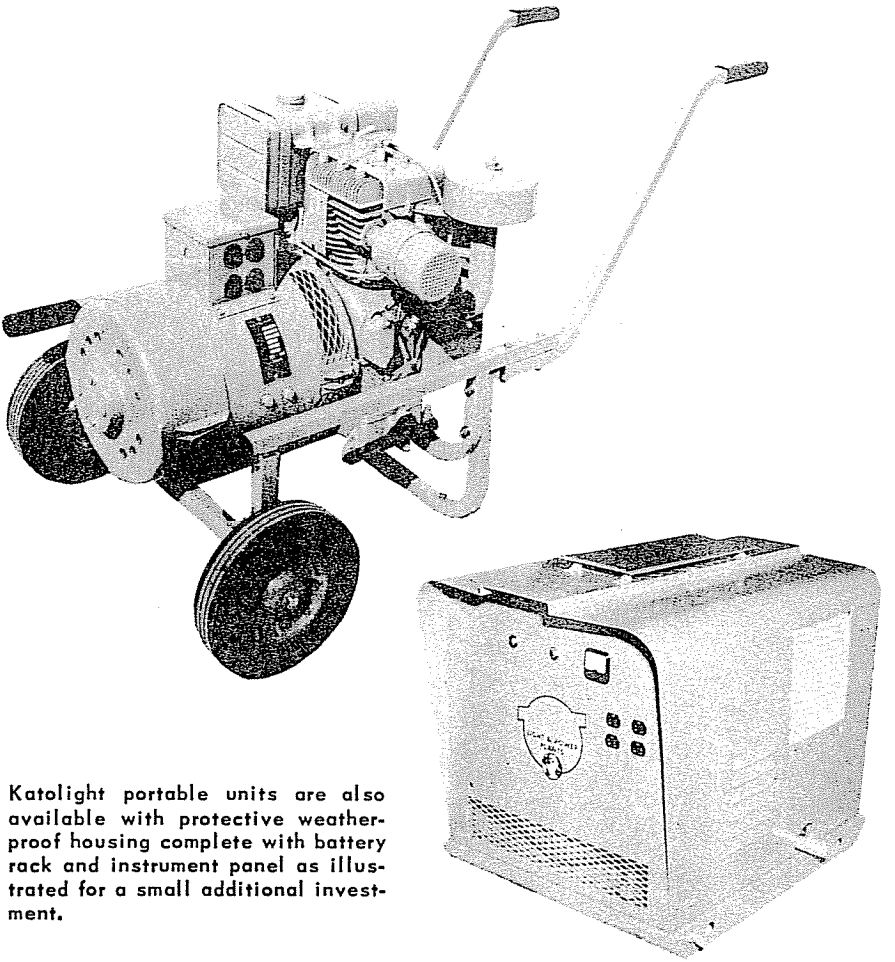
GENERATOR FRAME PRODUCES SHOCK WHEN TOUCHED

Cause	Remedy
Static charge built up by high speed belts, etc.	Ground generator frame.
Grounded armature or field coil.	Repair.

INSTALLATION OF 2 WHEEL DOLLY



KATOLIGHT PORTABLE GENERATING SETS ALSO AVAILABLE WITH THE FOLLOWING ACCESSORIES



Katolight portable units are also available with protective weather-proof housing complete with battery rack and instrument panel as illustrated for a small additional investment.

This series of lightweight, portable A.C. power plants offers nine models in popular sizes from 750 to 5000 watts. These husky, dependable plants are equally adaptable to provide emergency power when normal power fails, or for portable use to operate electrical tools, equipment and lights when regular power is unobtainable.

A small investment in a Katolight Power Plant of the proper capacity is low cost protection against possible loss of life and property and inconvenience caused by power failure due to storms, floods or accidents.

Lightweight generating plants which are ideal for many portable applications; for work crews, camps, radio receivers, fire department and emergency units. These models are easily transported in the trunk of a car and can be used on any location where utility electricity is not available. Plants are ready for operation with the addition of gasoline and oil.

INTRODUCTION

Before any Katolight Power Plant is shipped from the factory the generator is inspected and tested for performance. No unit is shipped unless it produces its rated capacity. Carefully unpack the generator set and visually inspect it for damage. If it is damaged, check with the transportation carrier for adjustment of the damage. If upon installation a new generator does not work properly, check all electrical connections and the generator speed before concluding the generator is defective.

GENERATOR DATA

Important data about your generator set is given on the nameplate attached to the power plant. Copy your power plant nameplate information in the spaces provided. Generator must be run at the speed (RPM) indicated on the nameplate. The load should not exceed the watts indicated on the nameplate. Load unbalance should not exceed 10% on 115/230 volt machines. When writing or calling Katolight for any information on the power plant, make sure to mention the Model, Type and Serial number from the nameplate or from this section.

INSTALLATION

LOCATION

There are several factors to be considered when choosing a good location.

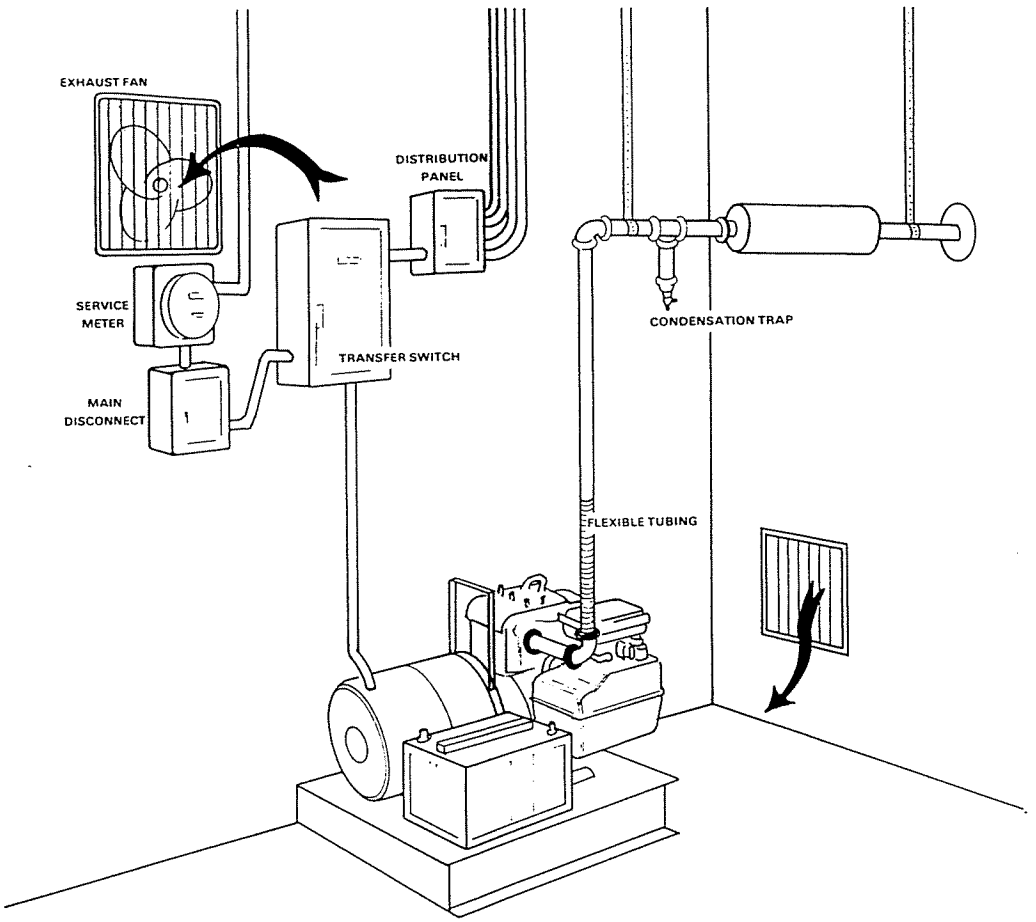
Moisture — All electrical equipment should be protected from excessive moisture which deteriorates insulation and causes short circuits.

Dirt — Dust, sand and lint cause excessive wear, not only to the engine but also to the generator. Install the unit in a clean location.

Heat — The engines used on these generators are air-cooled, so the temperature of the room in which one is located should not exceed 110 - 120° F. (43.3 - 48.9° C.).

Cold — Automatic engine-generators should be located away from freezing temperatures.

Exhaust — Exhaust fumes must be vented to the outside. The engine should be installed at least two feet from any outside wall. Using a too long or too small exhaust pipe can cause excessive back pressure.



INSTALLATION RECOMMENDATIONS

If the exhaust pipe rises above the engine, a condensation trap should be installed to prevent moisture from running into the engine. This trap consists of an ordinary pipe "T" in the exhaust pipe. At the lowest point of the T install a short length of pipe pointing downward and provide it with a drain plug to drain away the accumulated moisture.

Horizontally running pipe must be adequately supported by steel straps. Noise transfer can be minimized by supporting the pipe with isolators at the attachment points.

Flexible exhaust tubing should be used at the engine exhaust outlet to minimize vibration transfer. It can be used horizontally, vertically, or at a slant, but it should be kept in a fairly stright line to prevent excessive strain on the welded end connections. Also, try to keep the number of elbows in the exhaust pipe to a minimum.

The size of the exhaust pipe to be used depends upon the length of the run:

Diameter of engine exhaust hole	Length of the exhaust run up to 5 ft. use	5 to 15 ft. use	15 to 25 use
½ in.	½ in. pipe	¾ in. pipe	1 in. pipe
¾ in.	¾ in.	1 in.	1¼ in.
1 in.	1 in.	1¼ in.	1½ in.
1¼ in.	1¼ in.	1½ in.	2 in.

If the exhaust pipe passes through a wood wall or one of any other combustible material, take necessary precautions to eliminate a fire hazard. The muffler furnished with the unit may be installed at the end of the exhaust pipe outside the building to silence the exhaust.

The National Board of Fire Underwriters Standard for the Installation and Use of Combustion Engines and Gas Turbines states:

"Exhaust pipes passing directly through combustible walls or partitions shall be guarded at the point of passage by one of the following methods:"

a. "Metal ventilated thimbles not less than 12 inches larger in diameter than the exhaust pipe; or

b. "Metal or burned fire clay thimbles built in brick work or other approved fire-proofing materials providing not less than 8 inches of insulation between the thimble and combustible material.

"Exhaust pipes shall be connected to or pass inside of a metal, masonry, or factory-built chimney when the exhaust gases go through a floor, ceiling, attic or concealed space. When an exhaust pipe is connected to a chimney, a muffler shall be installed between the engine and the point where the exhaust pipe enters the chimney. The exhaust pipe shall be extended up into the chimney beyond any other flue collars from other fuel-burning appliances which are vented into the chimney."

CONNECTIONS AND WIRING

All wiring from a power plant receptacle should conform to the National Electric Code and state and local regulations. Connecting the power plant to a house wiring circuit should be done through a transfer switch which will prevent damage to the alternator and circuit components if the commercial power is restored during operation. It will also prevent your power plant from feeding electrical current into the commercial power system.

If grounding is required in local codes, drive an approved ground rod into the ground as close to the plant as possible. Connect an approved ground clamp to the ground rod by running a no. 10 or 12 wire from the clamp to the battery negative terminal on the control panel or alternator ground lead.

WIRE

Use a sufficiently large insulated wire to connect load to generator. The size will depend largely on the distance, the permissible voltage drop between the plant and the load, and the amount and kind of load. Consult a competent electrician. Check national and local codes before installing.

For model 2HAB3 use no. 12 wire for distances up to 100 feet except for motor driven loads. Use no. 10 wire for distances between 100 feet and 300 feet and motors up to ½ H.P. Use no. 8 wire for distances over 300 feet.

For models 3.5HFB3, 3.5HFB3E, 5HFB3, 5HFB3E, and 7.5HFW3E use no. 10 wire for distances up to 100 feet, no. 8 wire for distances between 100 feet and 300 feet, and no. 6 wire for distances over 300 feet.

For battery cables on generators having battery charging features, use no. 4 or larger wire to connect the battery. Lead length should not exceed six feet.

DETERMINING LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor which will be operated by the power plant. The following chart lists approximate watts required for various electrical appliances.

APPLIANCE	WATTS REQ.
Light bulbs	See wattage on bulbs
Radio	40 - 200
Television	150 - 300
Vacuum cleaner	200 - 250
Automatic Washer	400
Air conditioner (¾ ton)	1,250
Refrigerator	325
Food Freezer	300
Furnace (oil)	700
Deep well pump	2,000
Electric range	600 - 10,000
Hot plate (per burner)	600 - 1,200
Toaster	600 - 1,130
Water heater	1,500 - 5,000
Glow heater	600 - 1,200
Heating pad	40 - 80
Sun lamp	250 - 1,000
Iron	600 - 1,200

OPERATION

Before starting the engine fill the crankcase with the proper grade of oil as directed in the engine instruction manual. Use a good grade of regular gasoline. Do not use Ethyl. Make sure the gas tank vent and the shut off valve are open.

The rated output of each generator is based on factory tests on typical units and is subject to and limited by the temperature, altitude, fuel and other conditions specified by the manufacturer of the applicable engine. Engine power will decrease 3½% for each 1,000 feet above sea level, and 1% for each 10° F. (5.6° C.) above standard temperature of 60° F. (15.6° C.).

NOTICE REGARDING ENGINES

This instruction book covers only the generator, not the engine. See the engine instruction book for any engine problems.

POWER PLANT CAPABILITIES

These Katolight electric alternator type power plants are designed to provide 60 cycle alternating current at 3600 RPM. The output voltage is 115 volts, 230 volts, or a combination of 115/230 volts depending on the model. All units are equipped with solid-state exciter systems and are coupled directly to the engine for permanent alignment.

The alternator is inherently self-regulating and its output automatically adjusts to the load. The alternator will not be damaged if it is operated at no-load condition. Your alternator has a large overload capacity, sufficient to handle momentary loads (such as starting motors) approximately 25% above its rating and 10% overloads for ¼ to ½ hour.

STARTING AND STOPPING

All engine generators can be started manually by use of a crank, rope, or recoil starter. Check oil level before starting.

Manual start engines can be started only at the engine.

Refer to engine instruction book for detailed instructions on starting and stopping engine.

Controls for starting and stopping the plant automatically are also available. **Emergency transfer controls** are designed to automatically control the plant if it is to be used as a standby generator. If the main source of power fails, the **Automatic transfer switch** will sense the failure, will start the engine generator, and will transfer the load from the main source to the engine-generator. When the power failure is corrected the automatic transfer switch will transfer the load back to the main source and stop the engine.

REQUIRED OPERATING SPEED

The engine generator must be run at the proper speed in order to furnish the electrical power it was built to produce.

All air-cooled engines used for portable generators with standard mechanical governors have a tendency to slow down when a load is applied. The governor on the engine is designed to hold the speed as nearly constant as possible. When the electrical load connected to the generator is increased, the engine is more heavily loaded and the speed droops slightly. This slight decrease in speed, together with the "voltage drop" within the generator itself, results in a slightly lower voltage when the generator is loaded to its full capacity.

The following amperes are produced at 115 volts and at 230 volts for the various generator wattages shown.

WATTS	AMPERES AT 115 VOLTS	AMPERES AT 230 VOLTS
2000 (2HAB3)	17.39	NA
3500 (3.5HFB3 & 3.5HFB3E)	30.43	15.21
5000 (5HFB3 & 5HFB3E)	43.48	21.74
7500 (7.5HFW3E)	65.22	32.61

Although individual units and models may vary slightly, the normal voltage and frequency of typical 60 cycle engine-driven generators described in this book are approximately as follows:

Load Applied	Generator Speed 2 Pole	4 Pole	Frequency	Generator Voltage 115 V. Plants	230 V. Plants
None	3660	1830	62	129	258
Half	3600	1800	61	120	240
Full	3510	1755	60	115	230

For 50 cycle generators the corresponding speeds, frequencies and voltage would be approximately as follows:

Load Applied	Generator Speed 2 Pole	4 Pole	Frequency	Generator Voltage 110 V. Plants	220 V. Plants
None	3050	1525	52	122	245
Half	3000	1500	51	115	230
Full	2925	1462	50½	110	220

The speed of the engine is carefully adjusted at the factory so that the generator produces the proper voltage and frequency. For all normal usage the speed setting should not be changed. If the generator is being run continuously on a very small load, it may be well to lower the speed slightly; if it is being used constantly at full load, it may be well to raise the speed slightly. Whenever making any speed adjustments check the unit with a voltmeter, tachometer, or frequency meter.

Unless the engine is equipped with a special idling or low speed switch, the engine must be run at the specified speed at all times.

The output voltage should be checked periodically to insure proper operation of the generating plant and appliances. If the generator is not equipped with a voltmeter, use a portable meter.

USE OF ELECTRIC MOTORS

Electric motors require more current (amperes) starting than running. Split-phase motors are difficult to start and require 5 to 10 times as much current to start as to run, dependent on the NEMA code letter rating. Capacitor motors require 2 to 4 times as much current to start as to run. Repulsion Start Induction Motors require 1½ to 2½ times as much current to start as to run.

The chart below shows the approximate current required to run and start 115 volt, 60 cycle, NEMA Code F induction motors under average load conditions.

HORSE POWER	RUNNING AMPERES	STARTING AMPERES
1/6	4.4	22 to 24.60
1/4	5.8	29 to 32.42
1/3	7.2	36 to 40.29
1/2	9.8	49 to 54.78
1	16.0	80 to 89.44

The NEMA code letter assigned by the motor manufacturer will govern the starting (locked rotor) current surge. The chart below shows the NEMA code letters and their corresponding range of multipliers for the starting current requirement in amperes.

NEMA CODE LETTER MOTOR RATING	RATIO OF RUNNING TO STARTING (LOCKED ROTOR) AMPS
A	0 – 3.14
B	3.15 – 3.54
C	3.55 – 3.99
D	4.0 – 4.49
E	4.5 – 4.99
F	5.0 – 5.59
G	5.6 – 6.29
H	6.3 – 7.09
J	7.1 – 7.99
K	8.0 – 8.99
L	9.0 – 9.99
M	10.0 – 11.19
N	11.2 – 12.49
P	12.5 – 13.99
R	14.0 – 15.99
S	16.0 – 17.99
T	18.0 – 19.99
U	20.0 – 22.39
V	22.4 – and up

Here is an example of reading the chart:
The starting current for a Code F motor with a running current of 10 amps would be 5 to 5.59 times the 10 amp running current, or 50 to 60 amps.

Running current for 230 volt motors is half that of the 115 volt motors of the same size. Some dual voltage (115/230 volt) motors are difficult to start on 230 volts when driven by engine-generators and can be started more easily when connected to operate on 115 volts. This is particularly true of "Capacitor Start – Induction Run" motors. A 230 volt motor which cannot be started on the 230 volt circuit of a 115/230 volt generator usually can be started on a 115 volt circuit.

If an electric motor, requiring a little more output than the generator can produce is connected to it, it will operate but will not reach a high enough speed for the centrifugal switch to disconnect the starting winding. The 115 generator output voltage may drop to 70 or 80 volts. Running the generator

under these conditions may result in damage to the generator armature as well as the motor windings.

Because the heavy surge of current required for starting motors is needed only for an instant, the generator will not be damaged if it can bring the motor up to speed in a few seconds. If difficulty is experienced in starting motors, turn off all other electrical loads and, if possible, reduce the load on the electric motor.

MAINTENANCE

The generator of your plant consists mainly of field frame, field coils, armature, a set of brushes, brush holder assembly, end brackets, a fan mounted on the armature to keep the generator cool, and a control box.

Brushes: Check the brushes for wear after about 1000 hours of operation and every few hundred hours of operation thereafter. They should be replaced when worn down to 3/8 inch. Whenever replacing brushes, remove them one at a time and put the screws back in the brush holder to hold the lead wire terminals in place.

Commutator: Keep the commutator free from carbon dust or other dirt with a lint-free cloth. The Commutator should be smooth and shiny. If it is rough or black, polish it with a commutator dressing stone or with No. 00 sandpaper. (Never use emery cloth).

A hard mica is used as an insulator between the commutator bars. This is undercut about 1/32 inch below the surface of the bars. As the copper wears down, the harder mica forms ridges. To repair this condition the armature should be removed from the unit, the commutator resurfaced, and the mica undercut by a qualified repairman.

Do not use lubricants of any type on the commutator.

Collector Rings: These are two or three copper rings located at the end of the armature. Their surfaces should be kept highly polished by occasionally using a crocus cloth.

Bearing: There is only one bearing in these generators (some small models have none). It is a grease-sealed bearing and requires no further lubrication. If the bearing becomes worn or loose, replace it.

Disassembly: If it becomes necessary to recondition or replace the armature the field shell assambly must be removed as follows:

Loosen the nut on the end of the armature shaft and remove the fan. Also remove the brushes, and, as each brush is removed, remount the lead wire terminal to its original location so the wires will not be crossed. Remove the nuts from the stud bolts holding the field shell to the adaptor end bell. Use a hammer and chisel on any convenient place on the field frame to pry and separate it from the adapter end bell. After movement has been started, the entire field shell and brush rigging assembly can be removed.

The taper of the generator armature is accurately fitted to the taper on the engine crankshaft. In order to remove the armature, put the nut back on the through-bolt to protect the threads, and while pulling the armature outward with one hand strike the end of the through-bolt with a hammer. You may also tap the steel core of the armature to loosen it from the engine shaft.

ROUTINE ENGINE CARE

Study the engine manual supplied with your unit for more detailed information.

Oil: Always check the oil reservoir before starting the engine, as well as at the intervals specified in the engine instruction book. Do not add oil when operating the engine. Check lube oil level each time fuel is added.

Air filter: To clean the air filter, remove it, and wash it with gasoline. Allow it to dry; then dip it in clean engine oil, and shake out the excess. Fill it with light engine oil to the line indicated.

Gasoline: Use a good grade of regular gasoline. Be sure that the small vent hole in the gasoline tank cap is not clogged. When storing the unit, drain the gasoline from the tank and carburetor to avoid build-up of gum deposits.

MONTHLY PLANT SERVICE

Spark plugs: Clean and reset gap between electrodes to .025 gap. More frequent service may be required if leaded fuels are used.

Contact points: Contact points in the magneto system can be resurfaced by using an ignition file. (See Engine Manual for magneto service and tests).

Sediment bowl and screen: Clean them, and be sure the gasket is in good order.

Fuel line: Clean it by disconnecting the gasoline line at the carburetor. Blow through the gas line to clear it. Remove the shut off valve and clean the screen. Alcohol or acetone will dissolve any gummy deposits.

Exhaust system: Check it, and tighten and replace parts when necessary.

Battery: Make certain all connections are clean and tight. Keep the electrolyte level above the plates by adding clean distilled water. Do not over-fill.

For engine warranty and other engine service instructions, see Engine Manual.

TROUBLE SHOOTING CHART

PROBLEM	CHECK	SOLUTION
1. Sparking at the brushes:		
Too much load.	Check output voltage with a voltmeter to make sure it indicates voltage as marked on the nameplate.	Reduce the load.
Brushes not seated properly. Dirty brushes and commutator.	Remove brushes and check for uneven wear or dirt on brushes or commuator.	Clean commutator and seat brushes with sandpaper.
Rough or irregular commutator.	Check for uneven wear on commutator and brushes.	If slightly worn use fine sandpaper. If very rough, pitted, or irregular, have a repairman resurface the commutator.
Open armature.	Check to see if coil lead is disconnected or if coil is open.	Resolder coil lead or have a repairman service it.
Brushes sticking in the holders.	Check to see that brushes move freely in holders.	Clean brush holders and brushes.
DC brushes lose tension.	Remove and examine DC brushes to check if brush springs have collapsed.	Replace DC brushes. Tension loss was caused by a defective or low battery used to crank the generator.
2. Voltage too low:		
Low engine speed.	Check speed with tachometer.	Increase speed of engine by adjusting speed regulator.
Too much load.	Check output voltage with a voltmeter to make sure it indicates the voltage marked on the nameplate.	Reduce load.
Brushes not seated properly. Dirty brushes and commutator.	Remove brushes and check for uneven wear or dirt on brushes or commutator.	Clean commutator and seat brushes with sandpaper.
Open armature.	Check to see if coil lead is disconnected or if coil is open.	Resolder coil lead or have a repairman service it.
Grounded, open or shorted field winding.	Check for breaks or shorts in the field.	Open or shorted fields should be replaced. A grounded field may be repaired by insulating where the grounding occurs.
Brushes sticking in the holders.	Check to see that brushes move freely in holders.	Clean brush holders and brushes.
3. Voltage too high:		
High engine speed.	Check engine speed with a tachometer.	Reduce speed by adjusting speed regulator.
4. Generator overheating:		
Overloaded	Check output voltage with a voltmeter to make sure it indicates the voltage and current marked on the nameplate.	Reduce the load.
Armature striking on pole pieces.	Make sure the generator bearings are not worn out and check the alignment of the brackets.	Replace bearings and realign the brackets if necessary. Tighten all bolts.
Poor ventilation.	Check air space around generator.	Make sure there is at least a 2 foot clearance on all sides of generator.
Short circuit in the field.	Check for localized overheating.	Open or shorted fields should be replaced. A grounded field may be repaired by insulating where grounding occurs.
Short circuited armature.	Check for breaks in armature insulation and for dirt on commutator bars. Look for localized overheating.	Remove dirt and clean. Replace armature if necessary.

PROBLEM	CHECK	SOLUTION
5. Generator will not crank:		
	Check battery and battery connections. Check battery size. A minimum 70 amp-hour battery is required. Check start switch or solenoid by connecting heavy jumper across large terminals.	Have battery charged. Clean terminals and posts. Replace battery with adequate sized battery. Replace if defective.
Generator cranks but engine will not start.	Refer to engine instructions.	Refer to engine instructions.
6. Battery problems:		
Battery discharges when sitting idle:	Check reverse current diode with ohmmeter to determine if diode is shorted.	Replace defective reverse current diode.
Battery will not take a charge:	Examine charge resistor.	Replace, if defective. Solder connection if there is an open in the circuit.
	Put ammeter in series with battery.	Reverse current diode is evidently open and should be replaced.
7. Generator fails to generate:		
Weak residual magnetism.	Very low output voltage (½ volt) reading on a sensitive voltmeter.	Flash the field coils with a 6 volt automotive battery, a 12 volt automotive battery, or 2 "D" size flashlight batteries. Stop the generator and remove the end cover. You will note the positive (+) lead from the field coil is connected to the rectifier terminal with a red dot. The negative (—) lead from the field coil is connected to the grounded A.C. brush holder. The + lead should be connected to the + side of the battery, and the — lead should be connected to the — side of the battery for about 10 seconds.
Short circuited armature.	Check for breaks in armature insulation and for dirt on commutator bars.	Remove dirt and clean. Replace armature if necessary.
Grounded, open or shorted field winding.	Check for breaks or shorts in the field. Carefully inspect the hot side of the terminals for evidence of a grounded condition.	Open or shorted fields should be replaced. A grounded field may be repaired by insulating where grounding occurs.
Brushes do not make contact.	Remove each of the D.C. (commuator) brushes to be sure that they are clean and free in the holder. Examine the brush springs to be sure that they have several ounces of tension.	Replace brushes if necessary. Always replace with a complete set of brushes.
Shorted condenser	Disconnect lead wire from brush holder.	If generator produces current with the condenser wire disconnected, replace it.
Defective rectifier.	Check the rectifier by disconnecting one of the shunt field leads. Use an ohmmeter to measure the resistance of two adjacent terminals with the leads from the ohmmeter first connected one way and then reversed. One reading should show a high resistance and the other a low resistance. Continue around the terminals clockwise. If any diode does not read out correctly, replace the rectifier module. A grounded field will cause the rectifier to give false readings.	If you find the field is grounded, repair or replace it and repeat the check. The rectifier may not have been damaged and will not have to be replaced. The rectifier can also be checked by separately exciting the the field coils, as explained above. With this excitation, output on the generator should be 70 to 90 volts with no load applied.

PROBLEM	CHECK	SOLUTION
Generator fails to generate (cont.)		
Open circuits	First, check for broken wires or loose connections between the generator field and the control panel. Second, disconnect battery wires (if any) from the generator. Raise all brushes from commutator and/or collector rings. Disconnect field leads from terminals. Touch one field lead with a test lamp probe. Touch the other field lead with the wire lead from the battery. If the test lamp does not light, the field circuit is open. (See figure no. 1)	Get the unit repaired by a qualified electrician or consult your Katolight Distributor/Representative or the factory.
Grounds in Armature/Rotor	Disconnect battery and A-C wires from the generator. Raise all brushes from commutator and/or collector rings. Place one test lamp probe on the clean surface of the armature shaft. If the test lamp lights, the armature winding is grounded. (See figure no. 2).	Get the unit repaired by a qualified electrician or consult your Katolight Distributor/Representative or the factory.

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order, please furnish the following information.

1. Always give model number, type number, and serial number.
2. Give the item part number and description. Give the quantity required of each item. Do not order by reference number or group number. If an old part cannot be identified return the part postage prepaid to your distributor or Katolight Corporation with a letter stating the reason for returning the part.

INSTALLATION OF TWO WHEELED DOLLY

TWO-WHEEL DOLLY

Katolight Portable Power plants come equipped with a carrying frame. A two-wheeled dolly is available as an optional accessory.

NOTE

Katolight Portable Units are also available with protective weatherproof housing complete with battery rack and instrument panel.

WARRANTY

Katolight warrants to the original purchaser that the product delivered herewith, so far as it has been manufactured, engineered or assembled by Katolight, is free from defects in material and workmanship, and will perform under normal use and service for a period of one year from date of shipment from Katolight, or 200 hours of actual operation, whichever occurs first.

The liability of Katolight under the Warranty specified herein shall be limited to the replacement or repair of the product, at the option of Katolight, without charge, F.O.B., Mankato, Minnesota. This Warranty does not obligate Katolight to bear the cost of labor or transportation charges in connection with the repair or replacement of defective products, nor shall it apply to a product upon which modifications, repairs or alterations have been made. This Warranty shall apply only when the equipment or product has been properly installed, serviced and operated under normal conditions, in accordance with the instructions provided for the specific unit.

Katolight shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall Katolight be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN, NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING, BUT NOT LIMITED TO, A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

OPERATING INSTRUCTIONS & SERVICE INFORMATION

FOR KATOLIGHT PORTABLE POWER PLANTS

Read this book before operating the plant and save for future reference.

Write the Model number, Type number and Serial number of the generator in the spaces below. Be sure to give these numbers when ordering parts or corresponding about the generator.

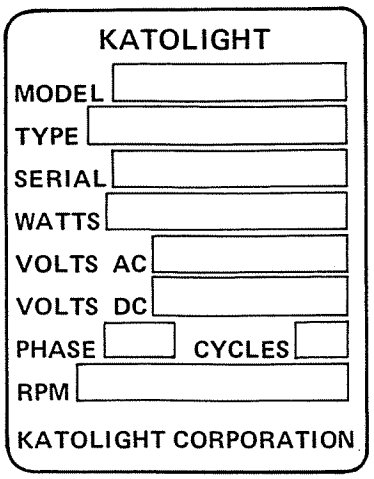
Form AD1/1-1170



GENERATOR DATA

Important data pertinent to your generator set is given on the nameplate attached to your electrical power plant. For handy reference copy your plant nameplate information in the spaces to the side of this paragraph. Additional information is contained in Tables A and B. FOR SATISFACTORY OPERATION GENERATOR MUST BE RUN AT SPEED (RPM) GIVEN ON NAMEPLATE AND LOAD SHOULD NOT EXCEED WATTS GIVEN ON NAMEPLATE. ON 115/230 VOLT APPLICATIONS LOAD UNBALANCE SHOULD NOT EXCEED 10 PERCENT.

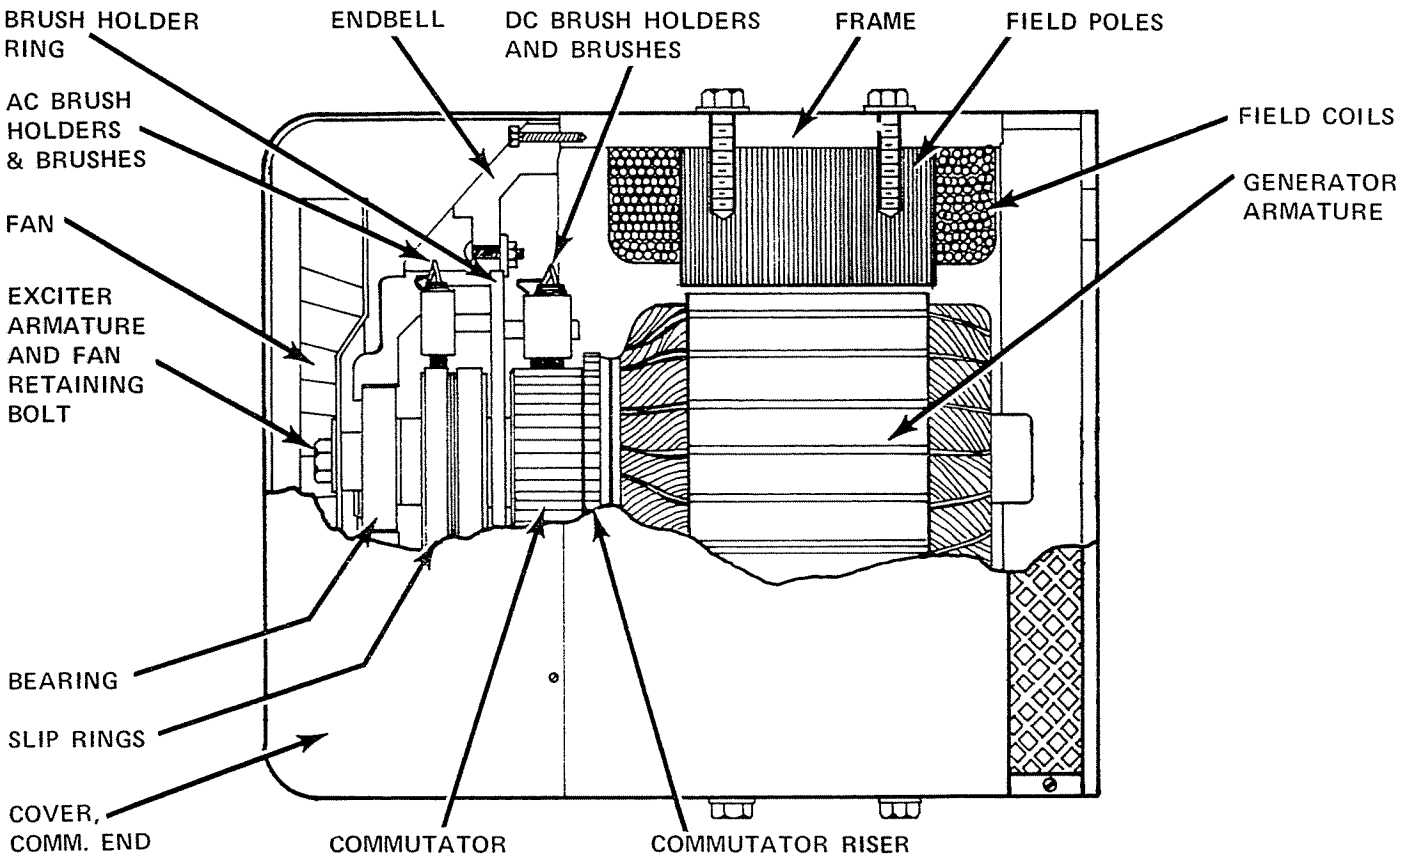

FIGURE 2 CUT-AWAY VIEW, TAPERED SHAFT TYPE REVOLVING ARMATURE GENERATOR

GENERAL INFORMATION

INTRODUCTION

Before any KATOLIGHT Power Plant is shipped from the factory the generator is inspected and tested for performance. No unit is shipped unless it produces its rated capacity. When unpacking the machine, inspect it carefully to see that no damage occurred in transit. If damage is noted, notify the transportation company immediately giving complete details as to the nature of the damage. Units are generally shipped with no lubrication in the engine crankcase and oil bath filters. Before placing unit in operation fill with lubricating oil as described in the engine manufacturers instructions.

If upon installation a new generator does not work properly, check all electrical connections and the generator speed before concluding the generator is defective. Observe the following precautions whenever operating the unit.

OPERATING PRECAUTIONS

Please follow the precautions listed below whenever operating your Power Plant.

CAUTION

PROVIDE SUFFICIENT VENTILATION. DO NOT OPERATE ENGINE IN ENCLOSED AREA. EXHAUST GASES CONTAIN CARBON MONOXIDE, AN ODORLESS DEADLY POISON.

STOP PLANT BEFORE FILLING WITH GASOLINE. AVOID SPILLING GAS ON HOT ENGINE, A FIRE AND SERIOUS INJURY COULD OCCUR.

IN APPLICATIONS WHERE GENERATOR IS CONNECTED TO SERVICE NORMALLY SUPPLIED BY COMMERCIAL POWER, INSTALL A MANUAL OR AUTOMATIC TRANSFER SWITCH. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN ELECTROCUTION OF PERSONNEL SERVICING COMMERCIAL POWER LINES.

AVOID EXPOSURE TO GENERATOR VOLTAGE. WHENEVER MAKING ELECTRICAL CONNECTIONS OR REPAIRING GENERATOR, FIRST STOP PLANT. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN ELECTROCUTION.

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order, please furnish the following information.

1. Always give MODEL NUMBER, TYPE NUMBER and SERIAL NUMBER.
2. Give the item part number and description. Give the quantity required of each item. DO NOT ORDER BY REFERENCE NUMBER OR GROUP NUMBER. If an old part cannot be identified return the part postage prepaid to your distributor or KATOLIGHT CORPORATION. Write a letter to the same address stating the reason for returning the part.

LOCATION

Provide sufficient ventilation. Do not operate the Power Plant in an enclosed area unless the engine exhaust gases are "piped" outdoors and there are no leaks in the exhaust system.

For best service the following factors should be taken into consideration;

1. Dirt: Foreign material such as dust, lint and abrasive particles cause excessive wear of bearings, brushes, etc. These materials will also clog the ventilation holes and cause excessive heating.
2. Moisture: All electrical equipment should be protected from excessive moisture. Excessive moisture could result in short circuits and grounds.

If the unit is to be left in the open, it should be covered whenever it is not in use. Ventilating ports should be cleaned periodically.

NOTE

KATOLIGHT Portable Units are also available with protective weatherproof housing complete with battery rack and instrument panel as illustrated for a small additional investment.

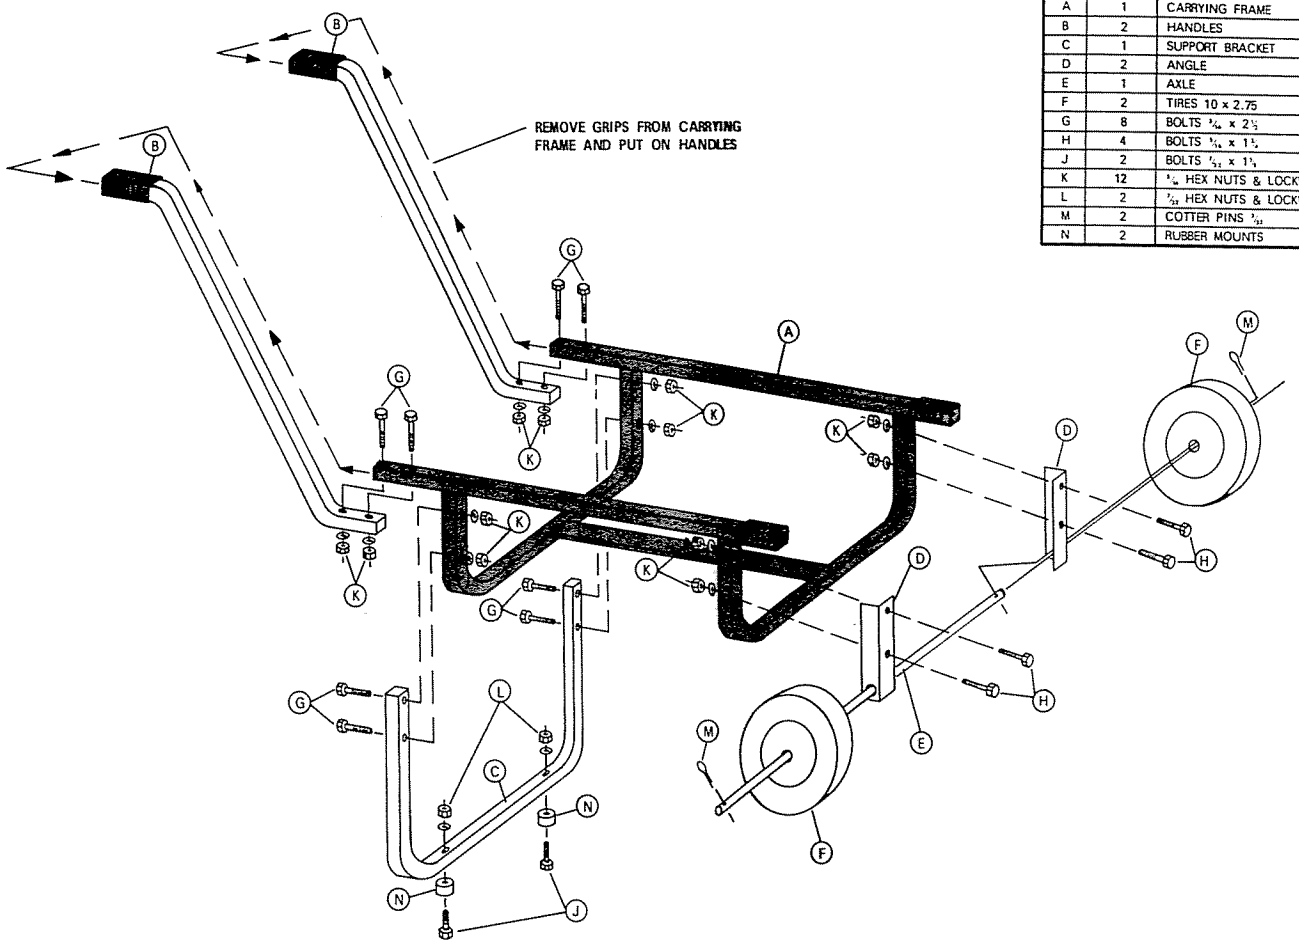

FIGURE 4 INSTALLATION OF 2 WHEEL DOLLY

INSTALLATION OF TWO-WHEEL DOLLY

KATOLIGHT Portable Power Plants come equipped with a carrying frame. A two-wheel dolly is available as an optional accessory. Figure 4 illustrates how parts comprising the dolly are attached to the carrying frame.

USE OF ELECTRIC MOTORS

Electric motors require much more current to start than to run. Most fractional horsepower motors take about the same amount of current to run them whether they are of the Repulsion-Induction, Capacitor, or Split-Phase type. Starting current, however, varies greatly. Repulsion-Induction motors are the easiest to start and usually require 1½ to 2½ times as much current to start as to run them. Capacitor motors usually require 2 to 4 times as much current to start them as to run them. Split-Phase motors are hardest to start with starting current about 5 to 7 times the running current.

The chart below shows the approximate current required to start and run 115 Volt, 60 Cycle motors under average load conditions such as a fan or blower. If the electric motor is connected to a hard starting load such as an air compressor it will require more starting current.

TABLE C
TYPICAL RUNNING AND STARTING CURRENT
FOR 115 VOLT, 60 Hz, SINGLE PHASE MOTORS

Horsepower	Running Amps All Types	Starting Amperes		
		Repulsion-Induction	Capacitor	Split-Phase
1/16	3.2	5 to 8	6 to 13	16 to 22
1/4	4.5	7 to 12	9 to 18	22 to 32
1/3	5.2	8 to 17	10 to 21	26 to 35
1/2	7.2	11 to 18	14 to 29	
1	13	20 to 33	26 to 52	

NOTE

IN APPLICATIONS WHERE SEVERAL MOTORS ARE TO BE STARTED EXCESSIVE OVERLOAD MAY BE AVOIDED BY STARTING THEM ONE AT A TIME, STARTING THE MOTOR THAT REQUIRES HIGHEST RUNNING AND STARTING CURRENT FIRST.

DETERMINING LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor which will be operated by the power plant. The following chart lists approximate watts required for various electrical appliances.

TABLE D

APPROXIMATE WATTS REQUIRED FOR ELECTRICAL APPLIANCES

APPLIANCE	WATTS
Lamp Bulbs	See Wattage on bulbs
Radio	40 - 200
Television	150 - 300
Vacuum Cleaner	200 - 250
Automatic Washer	400
Air Conditioner (¾ Ton)	1,250
Refigerator	325
Food Freezer	300
Furnace (Oil)	700
Deep Well Pump	2,000
Electric Range	600 - 10,000
Hot Plate (per burner)	600 - 1,200
Toaster	600 - 1,130
Water Heater	1,500 - 5,000
Glow Heater	600 - 1,200
Heating Pad	40 - 80
Sun Lamp	250 - 1,000
Flat Iron	600 - 1,200
Laundry Dryer	4,750
Electric Heat System	5,000 - 20,000

CONNECTING THE LOAD

These generators are supplied with various outlet and control boxes including units equipped with receptacles, meters and remote control stations. Generator lead wires terminate in lug type connectors in the outlet box. Always connect generator to the load as follows:

1. Follow the electrical connection drawings included as supplementary sheets with this manual. Should the drawings become lost, contact KATOLIGHT CORPORATION for additional copies stating the generator model, type and serial numbers.
2. Provide Fuse Protection: Generator should be protected with fuses or circuit breakers in accordance with the National Electrical Code and pertinent stat and local electrical codes.
3. Observe Nameplate Rating: Determine the load in amperes or watts. Load should not exceed the rating stamped on the generator set data plate. An overload could result in overheating and insulation breakdown.
4. Any generator which is installed for standby or emergency power must be equipped with a double throw switch for use when the power line fails. The switch transfers the load from the power line to the generator.

When the transfer switch is thrown to the "standby" side, the generator is connected to the load but the load is disconnected from the power line. Consequently no electricity produced by the generator can feed back to the power line where it would be hazardous to line repairmen.

PRECAUTIONS PRIOR TO INITIAL STARTING

Before starting the generator set for the first time the unit should be inspected as follows:

1. Check electrical connections to load. Refer to electrical connection diagrams supplied as supplementary information with this booklet.
2. Add fuel in engine tank, oil in crankcase. On models where oil bath air cleaners are used, add oil to filter. Refer to engine manufacturer's instructions.
3. Remove spark plug wires and ground them to the frame. Then turn the armature to see that it turns freely.
4. Check brushes to see that they are seated firmly on the commutator and slip rings and that they move freely in their holders.
5. Check the engine in accordance with engine manufacturer's instructions.

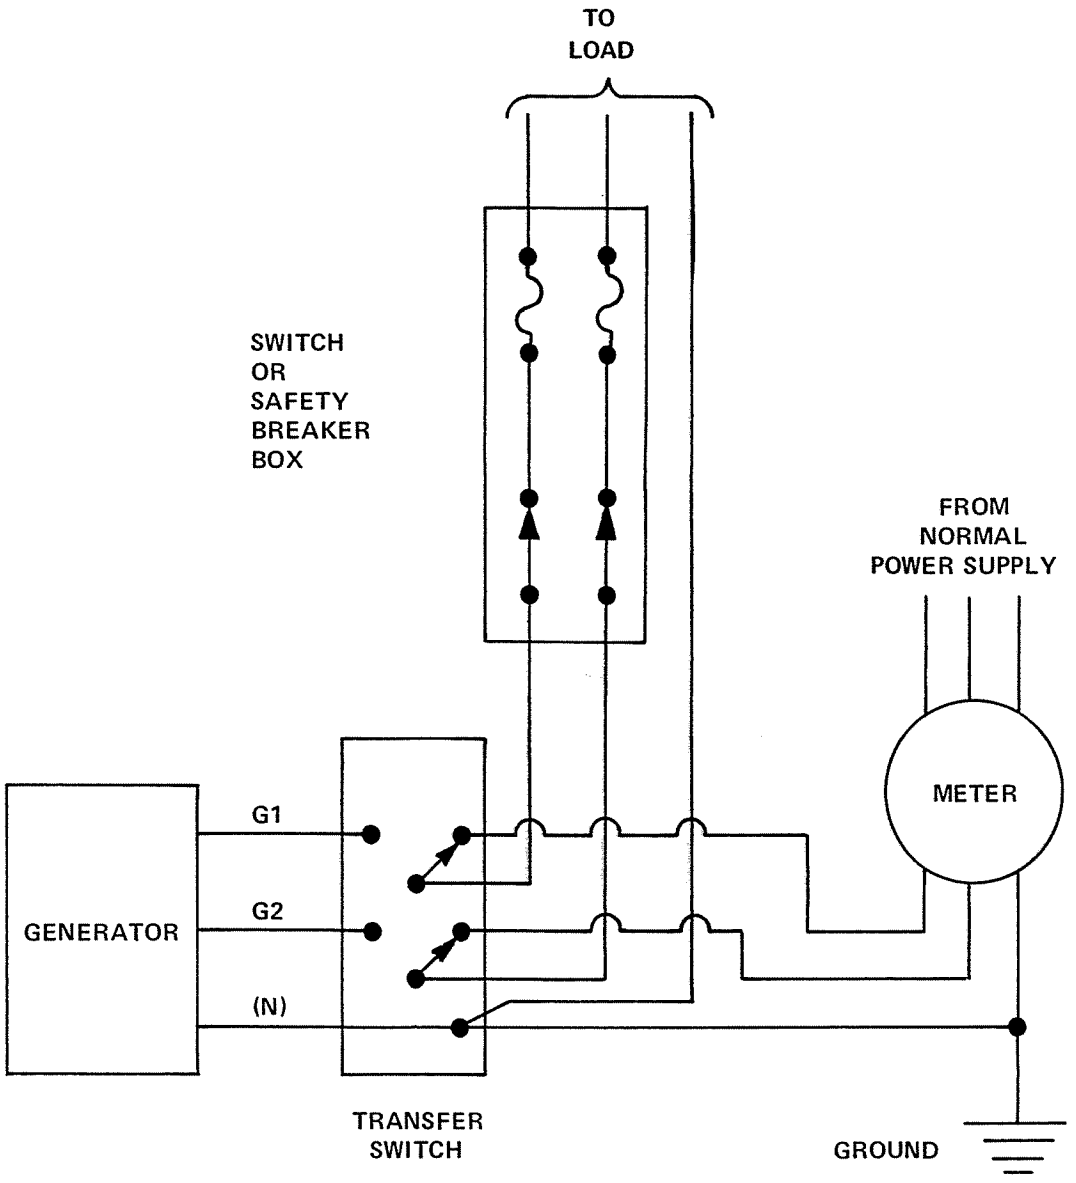

FIGURE 5 TYPICAL STANDBY EMERGENCY POWER INSTALLATION FOR SINGLE PHASE, 115/230 VOLT, THREE WIRE SERVICE WITH SOLID NEUTRAL

MAINTENANCE

MAINTENANCE

Brushes – Check the brushes for wear every few hundred hours of operation. They should be replaced when worn down to approximately 1/3 their original length. New brushes should be seated using fine sandpaper. (Do not use emery cloth). At least 80% of the brush surface should contact the commutator and slip ring surface. Whenever replacing brushes or removing them for service work, remove them one at a time and put the screw back into the brush holder. Excessive brush sparking and poor commutation can result from worn or dirty brushes, worn or dirty commutator and sliprings or poorly seated brushes. Improper brush spring tension can also cause poor commutation. Spring tension of about 4 pounds per inch of brush surface is normal.

Commutator and Slip Rings – If the commutator or slip rings get dirty or rough they can be cleaned with fine sandpaper. (Do not use emery cloth).

Bearings – All ball bearings used in these generators are packed with grease before assembly – no periodic greasing is required. If they become worn or rough they should be replaced. The replacement bearing should always be located on the shaft at exactly the same distance from the end of the shaft as the original bearing. Remove bearing using a puller. Tap replacement bearings onto shaft with a fiber or soft metal pipe that applies pressure to the bearing inner ring – never apply pressure on the outer ring. Heating the bearing before installation will make it slide more easily onto the shaft. A clean temperature controlled oven may be used, the temperature setting should not exceed 250 degrees F.

RESTORING RESIDUAL MAGNETISM

Residual magnetism can be restored by momentarily flashing the field with 6 to 12 VDC. The battery (+) lead must be connected to the lead wire on the positive DC brush and battery (–) lead must be connected to the lead wire on the negative DC brush. A reversal of battery polarity would result in reversal of field polarity.

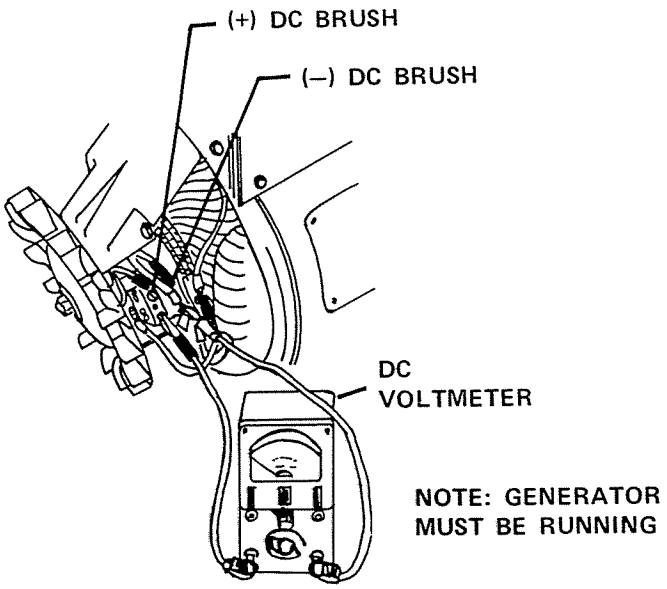

FIGURE 6 CHECKING EXCITATION VOLTAGE

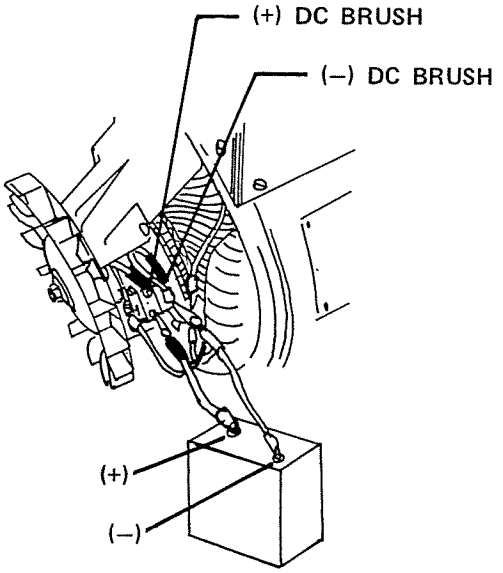

FIGURE 7 FLASHING FIELD

DISASSEMBLING AND ASSEMBLING GENERATOR

Two types of generators are described in this manual – a "close coupled" type and a "tapered shaft" type. The frame of both types is held to the engine by bolts inserted from the generator side into the engine block.

The close coupled type illustrated in Figure 1 utilizes a coupling which is bolted together. One half of the coupling is pressed onto the generator shaft and the other half onto the engine shaft. A cooling fan is installed between the two coupling halves. The generator armature is removed from the engine by removing the bolts which hold the coupling halves together.

The armature of the tapered shaft type illustrated in Figure 2 is held to the engine shaft by a bolt which passes through the center of the generator shaft and threads into the engine shaft. The tapered portion of the engine shaft locks into a tapered hole in the generator shaft.

The following procedures should be followed when assembling or disassembling either type.

1. Before starting to disassemble the generator or remove it from the engine raise the DC and AC brushes in their brush holders clear of the commutator and slip rings.

2. Disconnect wires one - at - a - time, tagging both the wire and its connection point.

3. Do not loosen and move the brush holder ring or the DC brush holders if these items do not require replacement. They were set at electrical neutral position at the factory.

4. If couplings are removed form either the generator shaft or engine shaft, reinstall couplings the same distance onto shafts as original couplings.

5. If bearings are replaced, the new bearing must be the same distance from the end of shaft as the original bearing. Failure to position bearing sufficient distance from end of shaft could result in high end thrust on bearing. (See "Bearings"). Bearings are positioned at the factory so that when the endbell is installed there is about 1/32 to 1/16 inch clearance between the bearing and it's stop in the bearing housing.

6. During reassembly make certain all bolts removed during disassembly are installed and tight. Use lock washers on all bolts.

7. Connect wires to their original connections. Tagging of wires and connection points during disassembly of the machine as described in step 2 will aid in determining correct connections.

8. Before placing generator in operation make certain brushes are seated and centered on the commutator and the slip rings. Visually inspect clearance between the DC brush holders and the commutator riser. About 1/8 inch clearance between brush holders and riser is normal.

9. Before placing the generator in operation, visually inspect alignment of generator armature with field poles. Excessive misalignment could result in low output voltage.

10. Before placing generator in operation, remove engine spark plugs and turn generator armature. Visually inspect unit for satisfactory clearance between rotating and stationary parts. Listen for noises which could be caused by parts rubbing together.

TROUBLESHOOTING

LOCATING TROUBLE

If the generator does not appear to be producing voltage, check the load circuit breakers or fuses. If a circuit breaker is tripped, reduce the load and reset the breaker. If fuses are blown, replace the fuses. Another common cause of poor generator operation is underspeed. Speed can be easily checked with a frequency meter or tachometer. The following troubleshooting chart lists various symptoms of poor generator operation as well as the possible causes and means of correcting the deficiencies.

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
No Voltage	Poor brush connection (either commuatator or slip ring brushes.)	Clean and adjust or replace brushes. Repair commutator and slip rings if necessary. Make certain that brushes do not bind on brush holders and that brush wires are connected properly. See additional information concerning maintenance of brushes, commutator and slip rings.
	Loss of residual magnetism in field poles, due to long inactivity, lightning striking system, overload or short circuit.	Raise DC brushes and connect positive and negative brushes to a 6 or 12 volt storage battery momentarily to magnetize field poles.
	Excitation (DC) leads open or shorted.	Check with continuity lamp or ohm meter. Replace leads if necessary.
	Too much resistance in field rheostat or resistor.	Reduce resistance of rheostat or replace resistor.
	Open field circuit in field coils, field rheostat switch or fuse.	A DC test lamp should be used to trace the open circuit. If open circuit is indicated repair or replace defective part.
	Shorted condensers.	Check AC output with condenser removed. Replace condenser if it is shorted.
	Short circuit in line or load.	Check for short in load by removing each individual motor or appliance from the line by switching it to off. Check the line by disconnecting the generator from the line at the generator terminal box.
	Open armature windings due to commutator throwing solder from riser because of excessive heating.	Commutator must be resoldered, turned and undercut.
	Coils shorted or open.	Check for open circuit with a continuity lamp and for short circuit with an ohmmeter. Replace coil if winding is open or shorted.
	Shorted slip rings.	Disconnect lead wires and check slip ring insulation with a megger. Repair or replace slip ring assembly if defective.
	Defective meters.	Repair or replace or bypass meters.
	Open ammeter shunt or filter choke.	Check for open circuit with a continuity lamp. Replace or repair defective part.
	Internal moisture, indicated by low resistance readings on megger.	Dry out the windings. Machines of small capacity may be dried out by putting them into a hot, dry room or by heating them up moderately from an outside source. Another method is to run unit several hours with full load current with generator lead wires short circuited. To do this, lower the AC voltage by adjusting the field rheostat to maximum resistance so that the stator coils are not overloaded.

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Low Voltage	Excessive load.	Reduce load. With 3 wire, single phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Low Speed: 1. Improper throttle setting. 2. Defective governor. 3. Defective carburetor. 4. Excessive load. 5. Defective bearing.	1. Correct throttle setting, check speed with frequency meter or tachometer. 2. Adjust, repair or replace governor. 3. Adjust, repair or replace carburetor. 4. Reduce load. 5. Replace bearing.
	Insufficient excitation.	Decrease field resistance by adjusting rheostat or removing resistor or adjusting resistor jumper wire.
	Line loss.	Increase size of line wire.
	High resistance connections. Connections will be warm or hot.	Make better connections electrically and mechanically.
	Reversed field coil or armature coil connection.	Connect properly. Flash field to magnetize field poles in correct polarity.
	Shorted field.	Test field coils for possible short by checking resistance with an ohmmeter or resistance bridge. Replace defective coil if necessary.
	Brushes dirty or not properly seated.	Clean or replace brushes and reseat.
	Slip rings or commutator dirty or in need of repair.	Clean or repair as necessary. See additional information concerning care and repair of slip rings and commutator.
	Low power factor.	Reduce inductive (motor) load. Some AC motors draw approximately the same current regardless of load. Do not use motors of larger horsepower rating than is necessary to carry the mechanical load.
	Weak field due to operating in warm temperature.	Improve the ventilation if generator is housed indoors. Field current can be increased providing the generator temperature does not exceed temperature rating stamped on the nameplate.
Fluctuating Voltage (May be indicated by flickering lights)	Irregular speed or prime mover (engine or electric motor).	Check and adjust governing device and carburetor if engine driven.
	Fluctuating load.	Stabilize load. The addition of a lamp load (resistance load) may compensate partially for load changes caused by intermittent motor operation.
	Poor brush contact.	Clean and adjust or replace brushes. See additional information concerning care of brushes, commutator and slip rings.
	Loose terminal or load connections.	Make better connections mechanically and electrically.

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Fluctuating Voltage (continued)	Generator overloaded.	Reduce load.
	Slip rings or commutator pitted or rough.	If slip rings or commutator cannot be cleaned up with sandpaper, turn rings or commutator on a lathe concentric with bearings.
	DC excitation voltage fluctuating.	Trace DC excitation through brushes, commutator and field coils and make reapirs as necessary.
	Shorted field coil.	Test field coils for possible short by checking resistance with an ohmmeter or resistamce bridge. Replace defective coils.
	Defective bearing causing uneven air gap.	Replace worn bearing.
High Voltage	Improper field adjustment (excessive magnetic field strength.)	Increase excitation field resistance by adjusting rheostat or adding a fixed field resistor.
	Excessive speed.	Adjust governor and carburetor if engine driven, making certain generator operates at rated speed as stamped on the generator nameplate.
	Faulty voltage regulator operation.	Try operating without regulator or replace regulator.
	Operating in sub-zero temperatures.	Increase field resistance.
Brush Sparking	Commutator defective: 1. Surfact pitted or rough. 2. High mica bars. 3. Outer surface not concentric with shaft.	Clean commutator. If sanding will not remove pitts, machine and undercut commutator.
	Slip rings defective: 1. Surface pitted or rough. 2. Slip ring insulation defective. 3. Surface not concentric to shaft.	Sand slip rings. If sanding will not remove pitts or rough spots machine slip rings.
	Brushes not in commutating plane.	Brush holder rings are set at the factory and marked in a position so that the brushes ride at electrical neutral points on the commutator. If brush ring is removed for any reason it should be replaced in the original position as marked.
	Loose brush holder.	Realign and tighten.
	Lack of brush pressure.	Adjust spring tension or replace brush tension spring.
	Improper grade of brushes.	If time permits, order brushes from the factory by part number. It is best to keep an extra set of brushes on hand and replace old brushes when approximately two-thirds worn.
	Dirty commutator or slip rings.	Sand lightly with 00 sandpaper.

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Brush Sparking (continued)	Generator overloaded.	Check ammeter readings and compare with nameplate rating. With 3 wire, single phase and 4 wire, three phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Open armature	Check for open circuit with a continuity lamp. Repair or replace armature if necessary.
	Grounded, open or shorted field winding.	Check for open circuit with a continuity lamp and for short circuit with an ohmmeter. Replace coil if necessary.
Overheating Most machines are designed to withstand a temperature rise of 50°C (see nameplate rating) 50 degrees Centigrade equals 122 degrees Fahrenheit.	Generator overloaded.	Reduce load. (Check ammeter readings and compare with nameplate rating.)
	Clogged ventilating screens.	Clean air passages.
	High room temperature.	Improve ventilation.
	Insufficient circulation.	Provide cross-ventilation.
	Operating with excessive voltage.	Check voltage drop in distribution lines and connections and adjust voltage as described in voltage deviation instructions.
	Low power factor.	Reduce inductive load (motors), or install power factor improvement capacitors.
	Unbalanced load on 3 wire, single phase or 4 wire, 3 phase generators.	The load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Motors operating off generator not designed for generator frequency and voltage.	Motors operating from generator must be of the same frequency and voltage as stamped on the generator nameplate.
	Generator coils or windings shorted or grounded.	Test field coils for possible short by checking resistance with an ohmmeter or resistance bridge. Replace defective coil if necessary.
	Excessive brush pressure.	Adjust pressure or replace brush tension springs.
	Coupling misaligned.	Align coupling.
	Bent shaft.	Straighten or replace.
	Endbells out of position.	Align endbells so that the air gap between the rotating part and the stationary part is equal at all points.
	Dry bearing.	Replace bearing.

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Mechanical Noise	Dry or defective bearing.	Replace bearing.
	Rotor rubbing on stator due to worn out bearing.	Replace worn bearings.
	Loose lamination.	Tighten bolts, dip in varnish, and bake.
Frequency Deviation	Generator speed above or below nameplate rating or fluctuating.	Adjust throttle and/or governor.
Radio Interference	Radio frequency interference generated by sparking brushes.	Connect .5 mfd. capacitors from all ungrounded brushes to the frame. Voltage rating of the capacitors should be at least twice the rated voltage of the circuit to which they are connected.
	Radio interference caused by leakage of static charge from generator shaft.	Install shaft grounding brush assembly, pruchased from the factory.
	Radio interference caused by electrical system of prime mover (engine or electric motor).	Suppress radio interference. Consult a competent radio repair man or electrician.
Generator Frame Produces Shock When Touched	Grounded armature or field coil.	Repair.

WARRANTY

This generator is warranted to produce its rated output as stamped on the nameplate when installed and operated in accordance with instructions.

It is warranted to be in good condition electrically and mechanically when leaving the factory.

It is warranted against electrical or mechanical defects in workmanship for a period of one year after shipment from the factory. Any parts found to be defective by factory inspectors after return to the factory, transportation charges prepaid, will be replaced or repaired free of charge. This does not include any component part or standard accessory such as meters, engines, relays, etc., made by other manufacturers, as these are subject to the warranties of those manufacturers.

Air Cooled Electric Alternator Type Power Plants, 3600 RPM, 60 Cycle, Statically Excited

GENERAL

Your new Katolight Electric Alternator Type Power Plant is rugged and compact, designed and built for dependable, trouble-free operation. It will provide years of reliable service if given the proper care. This manual contains information for operating and maintaining the Katolight Power Plants listed below. Study this information carefully before operating your plant. Keep the manual in a convenient location and refer to it for operation and maintenance instructions.

INSTALLATION

Unpacking

Carefully unpack the power plant and visually inspect it for damage. If the unit is damaged, check with the transportation carrier for adjustment of the damage.

Inside Operation

The exhaust products of gasoline engines contain carbon monoxide, which is poisonous and can cause death. Connect a flexible metal hose (see Figures 1 and 2) from the engine exhaust to the outside air. This hose should be at least as large as the exhaust port of the engine. Avoid sharp bends in the hose to prevent back pressure on the engine. If the exhaust hose rises above the engine, install a condensation trap at the lowest point.

Outside Operation

These plants may be operated out-of-doors. However, rain, snow, dust, dirt, etc., may damage the unit. Provide adequate protection.

OPERATION

These units have been operated and adjusted to handle their full rated capacity. Before starting the unit, refer to the engine manual for instructions and location of choke, stop button, gas shut off. WHEN STARTING THE GENERATOR DISCONNECT ALL LOADS. AFTER THE GENERATOR IS OPERATING, APPLY THE REQUIRED LOADS.

MODEL	WATTS	VOLTS	AMPS	PHASE	WIRE	START
2.5MGB3	2500	115	22	1	2	Manual
3.5MGB3	3500	115/230	15.2	1	3	Manual
3.5MGB3E	3500	115/230	15.2	1	3	Electric
5MGB3	5500	115/230	24	1	3	Manual
5MGB3E	5500	115/230	24	1	3	Electric
7.5MGB3E	8000	115/230	34.8	1	3	Electric

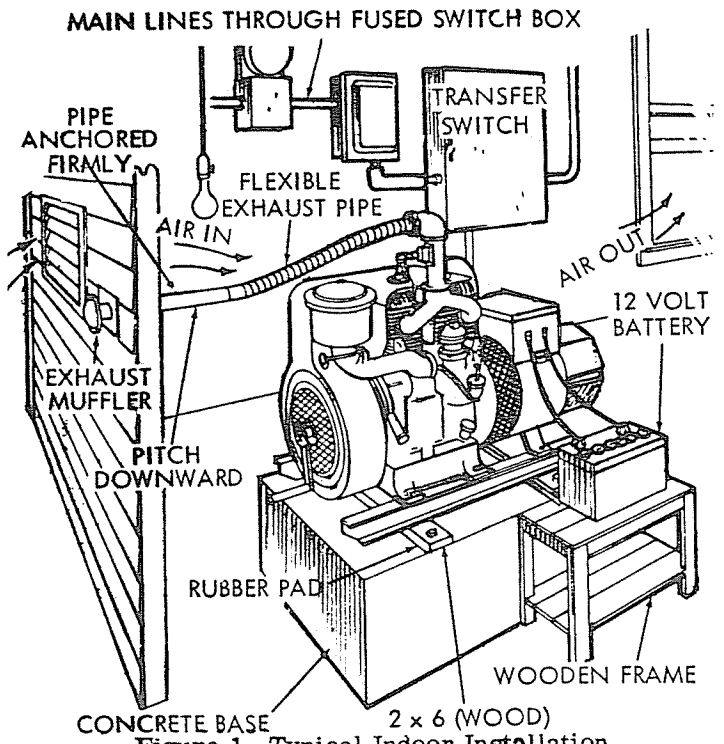

Figure 1. Typical Indoor Installation of Automatic Start Plant.

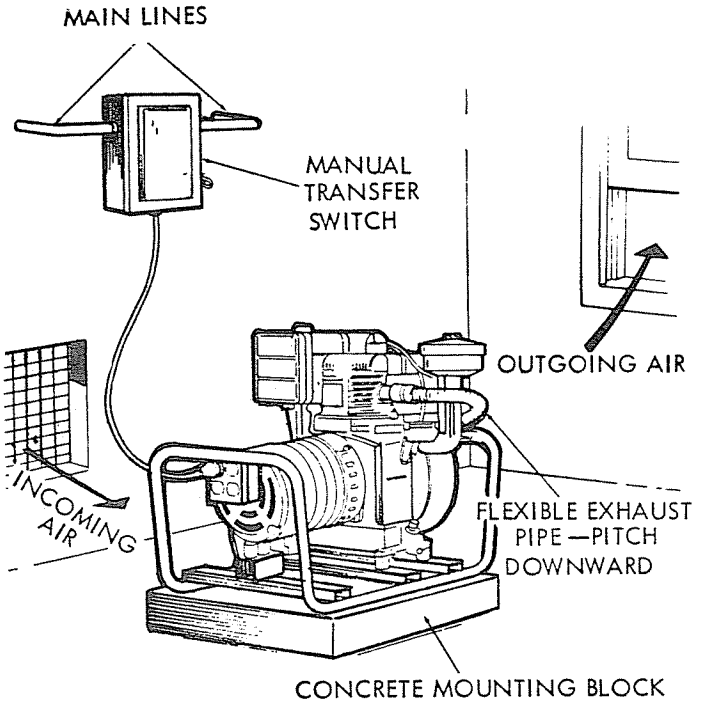

Figure 2. Typical Indoor Installation of Manual Start Plant.

These Katolight Electric Alternator type Power Plants are designed to provide 60 cycle alternating current at 3600 RPM. The output voltage is 115 volts, 230 volts or a combination of 115/230 volts, depending on the model. All units are equipped with solid-state exciter systems and are coupled directly to the engine for permanent alignment.

The alternator is inherently self-regulating and its output automatically adjusts to the load. The alternator will not be damaged if it is operated at no-load condition. Your alternator has a large overload capacity, sufficient to handle momentary loads (such as starting motors) approximately 25% above its rating and 10% overloads for 1/4 to 1/2 hour.

CONNECTIONS AND WIRING

All wiring emanating from a Power Plant receptacle should conform to the National Electric Code and state and local regulations. Connecting the Power Plant to a house wiring circuit should be done through a transfer switch. This will prevent damage to the alternator and circuit components if the commercial power is restored during operation. It will also prevent your Power Plant from feeding electrical energy into the commercial power system thus avoiding injury and damage.

If grounding is required in local codes, drive a 1/2" steel pipe into the ground as close to the plant as possible. This pipe must penetrate to approximately three feet. Connect an approved ground clamp to the pipe using a No. 10 or 12 wire from the clamp to the battery negative terminal on the control panel or alternator ground lead.

WIRING

When connecting the load to the generator, use a wire size capable of handling the load, this will prevent excessive voltage drops in your lead wires.

ABILITY OF CORD TO CARRY CURRENT (2 or 3-WIRE CORD)			
Wire Size	Type	Normal Load	
No. 18	S, SJ, SJT or POSJ	5.0 Amp. (600W)	7 Amp. (840W)
No. 16	S, SJ, SJT or POSJ	8.3 Amp. (1000W)	10 Amp. (1200W)
No. 14	S	12.5 Amp. (1500W)	15 Amp. (1800W)
No. 12	S	16.6 Amp. (1900W)	20 Amp. (2400W)

WIRING: Use sufficiently large insulated wire to connect load to generator, this will prevent excessive voltage drops.

CONSULT LOCAL ELECTRICAL CONTRACTOR FOR PROPER WIRE SIZE AS PRESCRIBED BY YOUR LOCAL ELECTRICAL CODE.

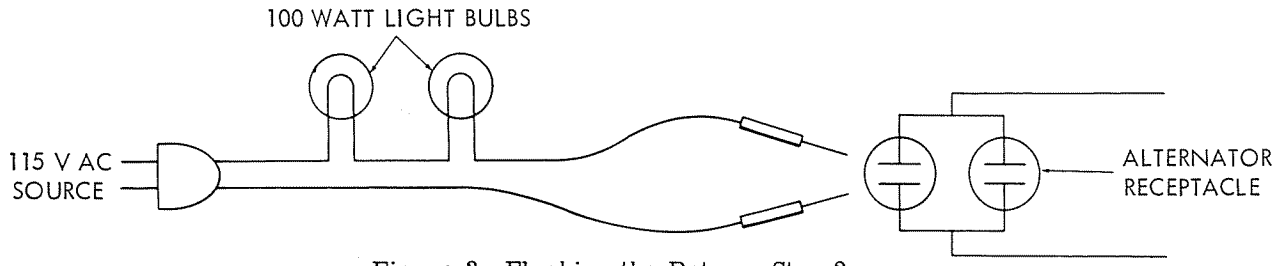

Figure 3. Flashing the Rotor - Step 2

MAINTENANCE

Brushes are the only alternator parts which normally wear. Inspect the brushes every 1000 hours of operation. If the brushes are worn to approximately 5/16 inch, replace them. Replace only in sets, never a single brush.

Flashing the Rotor

After long periods of storage, or if residual magnetism is distorted, it may be necessary to flash the rotor to restore the magnetism. This may be accomplished by the following procedure. Operate the unit at each step.

1. Run the engine at a higher-than-normal speed (approximately 4000 rpm). If this does not restore output, proceed to step 2.

2. Connect two 100-watt bulbs in series (see Figure 3) to a 115 volt source. Touch test probes to both sides of alternator 115 volt receptacle for approximately 1 second - or:

3. Connect two wires to a 1-1/2 - 6 volt battery (figure 4) using the free ends of the wires as probes. Touch the positive wire to the positive brush and negative wire to negative brush for approximately one second.

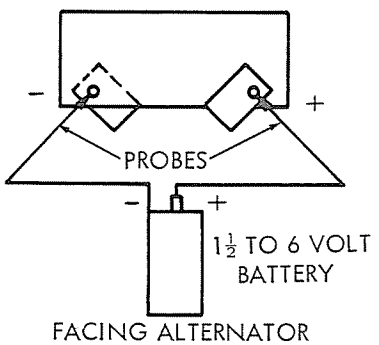

Figure 4. Flashing the Rotor - Step 3

Rectifier Testing

The silicon rectifiers can be damaged when subjected to either shorts or voltage transient conditions. To test the rectifiers, proceed as follows.

1. Disconnect the leads from the stator coil to the two terminals above the positive (+) brush.

2. Using the ohmmeter leads as probes (see Figure 5), touch the positive probe to the positive brush.

3. With the negative probe in contact with each rectifier terminal, no reading should occur. If a low reading is registered, the rectifier is shorted. If a high reading is registered the rectifier is open circuited. In either case replace the rectifier.

4. Reverse the ohmmeter leads; a low reading will register if the rectifier is not defective.

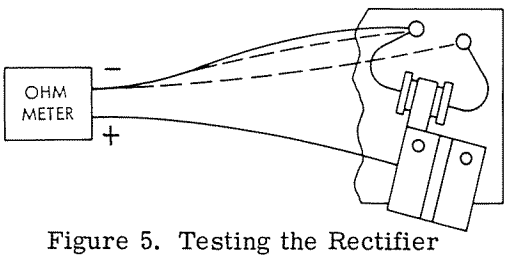

Figure 5. Testing the Rectifier

ALTERNATE RECTIFIER TEST

Your silicon rectifier can be tested with a 1-1/2 volt D-size flash light battery and the bulb from an ordinary flash light if no meter is available.

1. Repeat Step 1 of the above procedure.

2. Connect a wire from the base (-) of the battery to the negative stud on the brush holder.

3. Connect a lead from the light bulb to the brush holder assembly. Touch the light bulb base to the positive anode of the battery. The light bulb should not glow.

   By reversing the leads to the terminal board, the positive brush assembly should now complete the circuit allowing the light bulb to glow. Should the light bulb glow in either direction, the diode is defective. If the light bulb refuses to glow in either direction, the diode is also defective.

Frequency Adjustment

Check the frequency or rpm of your alternator as follows:

1. With the engine stopped, connect a cord with two 100 watt bulbs connected in series to the 115 volts alternator receptacles and to an outlet with 115 volts, 60 cycle power as illustrated in Figure 6. The two bulbs will burn dimly. CAUTION: Insert the Plug into the Alternator First.

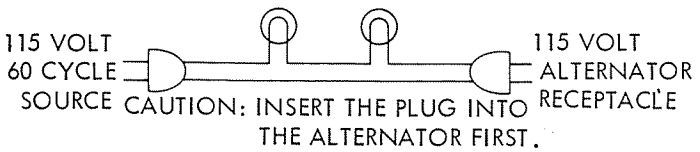

Figure 6. Adjusting the Frequency

2. Start the engine with the alternator connected as described in step 1. At no load, run the engine at 3700 rpm (approximately 63 cycles per second). The bulbs should flash approximately three times per second.

3. Apply a full rated load to the remaining alternator receptacle. At this load the engine governor should adjust the speed to 3600 rpm (60 cycles per second) and the bulbs should remain either on or off. The frequency of the alternator then matches the frequency of the commercial power source.

4. If the bulbs flash, the frequency of the alternator is either greater or less than the 60 cycle source. To adjust the alternator frequency, increase or decrease the engine speed until the flashing stops and adjust the engine governor to maintain that speed.

Storage Battery Care

If your Power Plant is electric start, maintain the storage battery as follows:

1. Place the battery in a well ventilated room of moderate temperature, free from vibration and not in contact with cement floor or stone wall.

2. Check the liquid level regularly. Add distilled water to keep the level 1/2 inch above the plates. Always use distilled water. DO NOT USE HYDRANT OR WELL WATER. Rain water may be used if it is caught in an earthen vessel.

3. To reduce corrosion, coat the terminals with a thin film of light grease.

4. If the battery is located in an unheated building, keep the battery fully charged to prevent freezing.

5. Check the condition of the battery by testing the specific gravity of the solution in each cell with a hydrometer. The specific gravity of the solution in a fully charged battery will be between 1.25 and 1.30.

6. Never allow the battery to remain discharged.

7. Charge the battery at regular intervals. Experience will indicate how often the battery will require charging. Charge the battery until all cells gas freely and the hydrometer reading stops rising in all cells.

TROUBLE SHOOTING CHART

	See Cause
No voltage	3, 4, 5, 7, 9, 10, 11, 12, 13, 19
Low voltage	2, 9, 10, 11, 13, 14
High voltage (normal range 130 volts no load, 105 volts full load)	18
Low power output	1, 2, 8, 9, 11, 12, 13, 14, 15, 17
Slow or no voltage build-up when starting engine	13, 14, 15, 17
Voltage build-up only after application of load	2, 3, 4, 5, 6, 9, 10, 11, 13, 20
Engine must be overspeeded to cause voltage to build up	2, 3, 13, 20
Intermittent voltage	9, 10, 11, 12
Repeated rectifier failure	18
Engine fires but does not come up to speed before stopping	1, 8, 14, 15, 16, 17
Inserted magnet rotor will not build up voltage	20
Bearing causes wear to shaft or housing	21, 22
Unit operates normally at rated speed but voltage does not rise above 90 volts	2, 6, 13

Cause	Remedy
1. Rotor rubbing	A. Adapter housing not properly attached to engine. Check for concentricity.
	B. Extreme wear of engine main bearing. Re-bush main bearings.
	C. Dirt or chips on the engine shaft taper. Clean up and re-assemble.
2. Low speed	A. Overload connected to engine. Remove load.
	B. Rotor rubbing. (See Cause No. 1.)
	C. Governor improperly adjusted. (See frequency adjustment, Page 2.)
	D. Carburetor improperly adjusted or dirty. See engine service manual.
	E. Ignition problems. Check engine service manual.
3. Low residual voltage	Flash rotor (see Page 2). If not successful, replace rotor with new rotor.
4. Rectifier shorted	Most often caused by over-speeding of engine. Replace rectifier, re-calibrate governor (See Page 2) making sure governor operates freely.
5. Faulty reactor	Open circuit, check for continuity; if open, replace.
6. Defective reactor	See wiring diagram. Short out winding with jumper wire, which is connected to the rectifier assembly. With engine operating at 3750 rpm, if output voltage is below 135 volts, replace reactor.
7. Stator open	Check continuity for open circuit; if open, replace.
8. Shorted turns in stator	A shorting of a few turns will cause overheating and burn out these turns. Severe shorting of many turns will cause the engine to be badly loaded without a load connected to the generator. Replace stator.
9. Loose or poor connection	Check tightness of all terminal screws. Check all connections for signs of wearing which would indicate poor connections and loss of voltage and power.
10. Excessive brush wear	If brushes are shorter than 5/16", replace.
11. Severely coated slip ring	Ring can become severely coated, particularly if operated in a high oil atmosphere. Re-polish slip rings with extra fine sandpaper. WARNING, DO NOT USE EMERY PAPER!
12. Defective outlet receptacles	Replace.

Katolight Service - Master Repair Manual - Page 192

13. Reactor polarity reversed	Check color coding against wiring diagram or reverse connections of series winding at reactor.
14. Extreme overload connected to generator	Remove load.
15. Faulty carburetion	Check engine service manual.
16. Out of gasoline	Add gas.
17. Out of oil	Add oil and operate engine at 1/4 load for approximately 2 hours to permit any possible scoring to "heal" before applying full load.
18. Engine speed to high	Check for sticky governor. Re-set governor for 3600 rpm at full load. (See page 2.)
19. Open rotor circuit	Check for continuity; if open, replace.
20. Polarity reversed at slip ring	Read brush polarity with dc voltmeter. The positive brush must be nearest the rotor bearing. If not, connect accordingly.
21. Bearing not properly secured	When re-assembling a unit, always clean thoroughly and apply Loc-tite to the outside and inside diameter of bearing before inserting into place.
22. Rotor through-bolt loose	Tighten.

KATOLIGHT
Telescoping Portable Flood Light Tower

Protolight III
Protolight VI
Protolight VIII

The Katolight Telescoping Portable Flood Light (Protolight) Towers are a valuable addition to the Katolight Product Line of dependable standby and emergency power generating equipment. These units combine an efficient diesel air cooled Katolight engine generator set with longlife, power spotlights on an adjustable tower to bring light to unlikely locations.

The Protolight Tower is a portable source of illumination and power (single phase, 240 volts and 120 volts, 60 hertz). The engine generator is oversized in each unit so that a small amount of power for hand tools may be taken at the same time the lighting is being used.

These units are weather-resistant and mobile with housing and trailer mounting as standard. The tower itself is adjustable to a height of 30 feet, from an elevating positive lock winch on the trailer.

The lighting fixtures used are 1000 watt, high intensity discharge, metal halide, 10,000 hour life. Each lamp and ballast will draw 1100 watts operating.

The engine is diesel, air cooled, 1800 RPM pressure air cooled full pressure lube oil system.

The generator is 4 pole, 1800 RPM, revolving armature, 120/240 volts AC, 60 hertz.

The primary benefits to the user of a Katolight Protolight Tower are:

1. Portable lighting in isolated locations and in times of disaster.
2. Auxiliary power for hand tools.
3. Katolight reliability.

Protolight VIII

RATINGS, SIZES AND WEIGHTS

Model	KW	Size Transport Position	Net Weight	Export Gross Weight	Export Package Dimensions
III	4.5	71"W x 203½"L x 94½"H	2,860	5,360	78"W x 216"L x 96"H
VI	8.0	74"W x 202¼"L x 100"H	3,120	5,620	80"W x 212"L x 100"H
VIII	12.0	74"W x 220¼"L x 100"H	3,350	5,850	80"W x 230"L x 100"H

For further specifications, please see the back of this sheet.

Form TPFLT-379

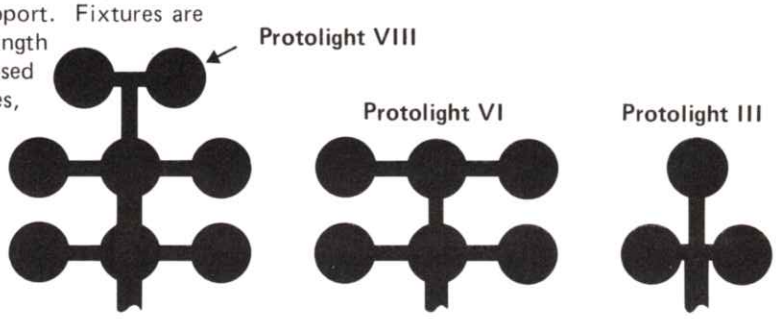
SPECIFICATIONS

Model	Number of Lamps	Lumens	Average footcandles of illumination over 1½ acre area (approximately 6,000 sq. ft.)
III	3	300,000	1.4
VI	6	600,000	2.8
VIII	8	800,000	3.9

LAMPS

1000 watt, metal halide type power spotlight with nominal 1100 watt load. An average 100,000 lumen output per lamp is maintained at 10,000 hours burning 80% time life. Equipped with spring dome support, rough service arc tube harness, long life resistor and spring neck support. Fixtures are finished with corrosive resistant material and high strength lens. NEMA 4 beam spread. All lamp ballasts are enclosed in weather tight cast enclosures. Longlife lamps, fixtures, reflectors and lens are mounted on an automatic telescoping tower to nominal 30 feet. Tower when lowered to transport towing position, is provided with lock down device. The light tower is manufactured using rectangular high strength steel tubing. Each section is equipped with bearings to reduce friction and wear.

LIGHT CONFIGURATIONS



ENGINE

Unit powered by air cooled diesel engine developing adequate horsepower for continuous operation at 1800 RPM in accordance with manufacture's published specifications. Full pressure lube oil system is standard. Low oil pressure and high temperature shutdowns are provided for engine protection. Dry type air cleaner installed for dusty, dry environment. 12 volt heavy duty starting battery and charging circuit is included as well as a built in 30 gallon (110 liter) fuel tank with flexible lines.

ALTERNATOR

Alternator is 4 pole with revolving armature. Statically exciter alternator rated at 1800 RPM, 60 cycle, single phase and unity power factor. Auxiliary power available from oversized alternator at 120/240 AC thru two 120 volt receptacles and one grounded three prong 24 twist lock receptacle with circuit breakers. Complete engine alternator, engine controls (including low lube oil pressure, high temperature, diesel start, stop, shutdown device, and oil pressure gauge), and service receptacles are in a weather environmental protective (enclosure) housing, which provides environmental protection, air temperature control and open serviceability.

TRAILER

- The trailer is equipped with four adjustable jack stands for stabilizing and with retractable outriggers extendable around housing to adjustable lengths and height to adjust for uneven terrain. Wind stability estimated at 45 MPH with outriggers extended and correctly positioned. Connections for optional wire stays are provided. Trailer available with two elevating positive locking winches, one for tower tiling and one for tower extension.
- Leaf spring, high speed suspension with wheels and tires.
- Towing bar available with either lunette ring or ball hitch connections are required and safety chains.

TOWER

The Protolight Tower is square tubing of telescoping 3 section construction. The tower is elevated to vertical from horizontal by a self-braking winch mounted on the trailer frame. The tower is raised vertically by means of a self-braking winch mounted on the lower section of the tower.

Materials and Specification May Change Without Notice.

ALTERNATOR DATA

The alternators described in this manual are single phase, 115/230 VAC, 1800 RPM revolving field brushless type with Static Voltage Regulators. Output voltage may be varied as desired within range of from approximately 5 percent higher to approximately 5 percent lower than the voltage given above, by turning the voltage adjust potentiometer.

Standard equipment includes a gear increaser and protective shield and a terminal box containing a voltage regulator, mainline breaker.

Important data pertinent to your alternator set is given on the nameplate attached to the alternator. Additional information is contained in Table A. For handy reference, copy your plant nameplate information in the spaces to the side of this paragraph. FOR SATISFACTORY ALTERNATOR OPERATION GENERATOR SHAFT MUST TURN AT 1800 RPM.

INTRODUCTION

Before any Katolight Power Take-off Driven Alternator is shipped from the factory it is inspected and tested for performance. No unit is shipped unless it produces its rated capacity. When unpacking the machine, inspect it carefully making certain no damage occured in transit. If damage is noted, notify the transportation company immediately giving complete details as to the nature of the damage. Units are generally shipped with lubrication in the gearbox. Before placing the unit in operation check to make sure that the lubrication is in gearbox. If not, fill Von Ruden gearbox with 1¼ lbs. EP90 gear oil. If unit has Apex gearbox, fill with 2½ lbs. EP90 gear oil. Maintain oil level on either gearbox slightly below check plug.

If upon installation a new alternator does not work properly, check all electrical connections and the alternator

nameplate for correct operating sped. Observe the following precautions whenever operating your Power Take-Off Driven Alternator.

CAUTION

DISENGAGE PTO WHENEVER TRACTOR IS IDLING. RUNNING ALTERNATOR UNDER SPEED COULD RESULT IN DAMAGE TO VOLTAGE REGULATOR AND ALTERNATOR.

PROVIDE SUFFICIENT VENTILATION. DO NOT OPERATE TRACTOR IN ENCLOSED AREA. EXHAUST GASES CONTAIN CARBON MONOXIDE, AN ODERLESS, DEADLY POISON.

STOP TRACTOR BEFORE FILLING WITH GASOLINE. AVOID SPILLING GAS ON HOT ENGINE, A FIRE AND SERIOUS INJURY COULD OCCUR.

IN APPLICATIONS WHERE ALTERNATOR IS CONNECTED TO SERVICE NORMALLY SUPPLIED BY COMMERCIAL POWER, INSTALL A TRANSFER SWITCH. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN ELECTROCUTION OF PERSONNEL SERVICING COMMERCIAL POWER LINES.

AVOID EXPOSURE TO ALTERNATOR VOLTAGE. WHENEVER MAKING ELECTRICAL CONNECTIONS OR REPAIRING ALTERNATOR, FIRST STOP TRACTOR. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN ELECTROCUTION.

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order, please furnish the following information.

1. Always give MODEL NUMBER, TYPE NUMBER, and SERIAL NUMBER.
2. Give the item part number and description. Give the quantity required of each item. DO NOT ORDER BY REFERENCE NUMBER OR GROUP NUMBER. If an old part cannot be identified return the part postage prepaid to your distributor or KATOLIGHT CORPORATION. Write a letter to the same address stating the reason for returning the part.

LOCATION

Provide sufficient ventilation. Do not operate tractor driven alternator in an enclosed area.

For best service the following factors should be taken into consideration:

1. Dirt: Foreign material such as dust, lint and abrasive particles cause excessive wear of bearings and clog ventilating ports causing excessive heating of unit.
2. Moisture: All electrical equipment should be protected from excessive moisture. Excessive moisture could result in short circuits and grounds.

If the unit is to be left in the open, it should be covered whenever it is not in use. Ventilating ports should be cleaned periodically.

DETERMINING THE LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor which will be operated by the power plant. The following chart lists approximate watts required for various electrical appliances.

TABLE B
APPROXIMATE WATTS REQUIRED
FOR ELECTRICAL APPLIANCES

APPLIANCE	WATTS
Lamp Bulbs	See Wattage on bulbs
Radio	40 - 200
Television	150 - 300
Vacuum Cleaner	200 - 250
Automatic Washer	400
Air Conditioner (¾ Ton)	1,250
Refrigerator	325
Food Freezer	300
Furnace (Oil)	700
Deep Well Pump	2,000
Electric Range	600 - 10,000
Hot Plate (per burner)	600 - 1,200
Toaster	600 - 1,130
Water Heater	1,500 - 5,000
Glow Heater	600 - 1,200
Heating Pad	40 - 80
Sun Lamp	250 - 1,000
Flat Iron	600 - 1,200
Laundry Dryer	4,750
Electric Heat System	5,000 - 20,000

USE OF ELECTRIC MOTORS

Electric motors require much more current to start than to run. Most fractional horsepower motors take about the same amount of current to run them whether they are of the Repulsion-Induction, Capacitor, or Split-Phase type. Starting current however, varies greatly. Repulsion-Induction motors are the easiest to start and usually require 1½ to 2½ times as much current to start as to run them. Capacitor motors usually require 2 to 4 times as much current to start them as to run them. Split-Phase motors are hardest to start with starting current about 5 to 7 times the running current.

Table C shows the approximate running current for single phase 115 volt motors.

NOTE

IN APPLICATIONS WHERE SEVERAL MOTORS ARE TO BE STARTED EXCESSIVE OVERLOAD MAY BE AVOIDED BY STARTING THEM ONE AT A TIME, STARTING THE MOTOR THAT REQUIRES HIGHEST RUNNING AND STARTING CURRENT FIRST.

INSTALLATION

MOUNTING ALTERNATOR

The alternator must be solidly bolted to a foundation, platform or bed of a trailer. All four feet on the alternator must contact the foundation or trailer bed. If space exists between a mounting foot and the foundation or trailer, first install shims to take up space and then install and tighten bolts.

TABLE C
TYPICAL RUNNING AND STARTING CURRENT
FOR 115 VOLT, 60 Hz, SINGLE PHASE MOTORS

Horsepower	Running Amps All Types	Starting Amperes		
		Repulsion-Induction	Capacitor	Split-Phase
1/16	3.2	5 to 8	6 to 13	16 to 22
1/4	4.5	7 to 12	9 to 18	22 to 32
1/3	5.2	8 to 17	10 to 21	26 to 35
1/2	7.2	11 to 18	14 to 29	
1	13	20 to 33	26 to 52	

GEARBOX LUBRICATION

Check oil level. If not full, fill with EP 90 Gear Oil. Maintain oil level slightly below check plug. **DO NOT OVERFILL.** Overfilling will cause heating and possible seal failure.

CONNECTING ALTERNATOR TO LOAD

Load can be taken from receptacles, a cord set or by connecting the alternator into an existing service.

Load taken from receptacles should not exceed receptacle rating and should never exceed alternator rating. The 115 volt duplex receptacles are rated 20 amperes while the 230 volt receptacles are rated 50 amperes.

Load taken from the 230 volt cord set when it is incorporated should not exceed 50 amperes.

When the alternator is connected into an existing service normally supplied by commercial power a transfer switch must be used.

NOTE	INSTALL ELECTRICAL LINES AND GROUND IN ACCORDANCE WITH APPLICABLE ELECTRICAL CODES

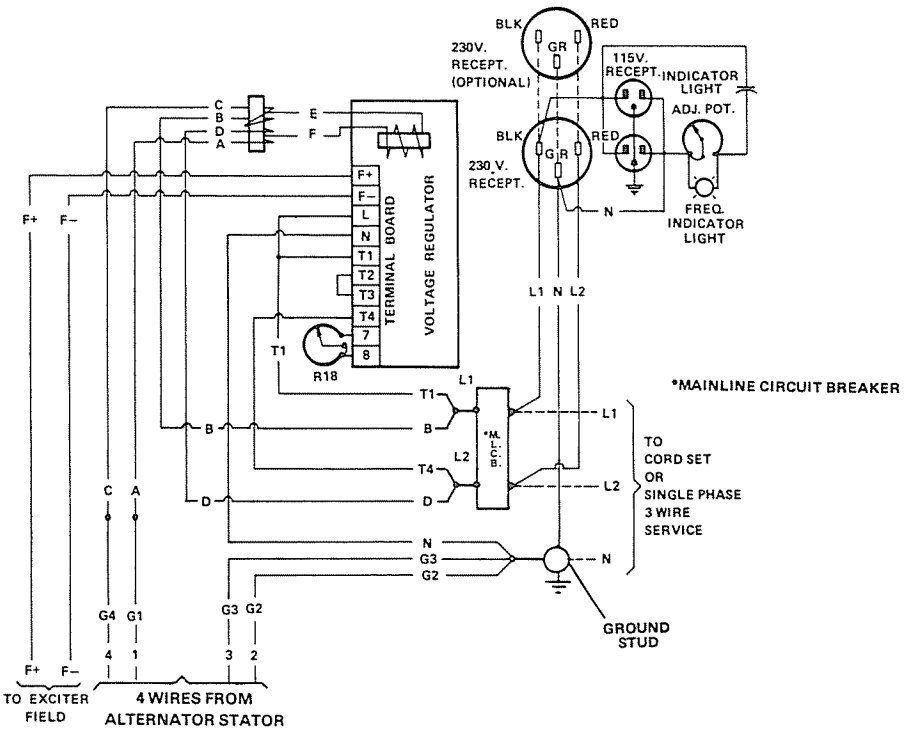

FIGURE 2 ELECTRICAL CONNECTION DIAGRAM, SINGLE PHASE, 4 WIRE AVR-1 ALTERNATOR

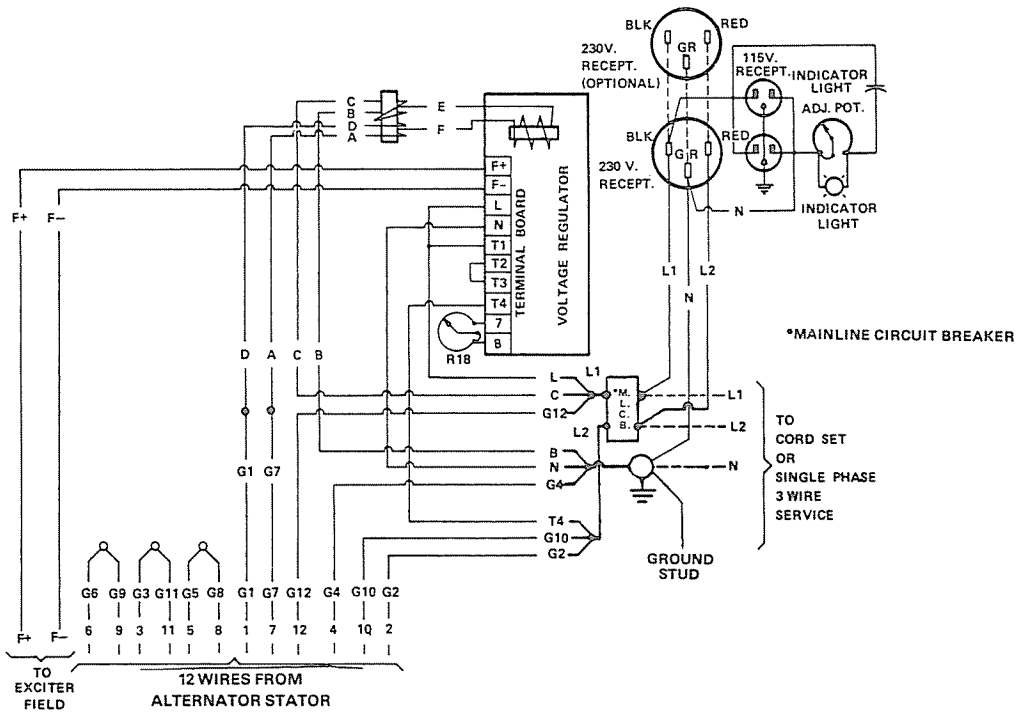

FIGURE 3 ELECTRICAL CONNECTION DIAGRAM, SINGLE PHASE, 12 WIRE AVR-1 ALTERNATOR

OPERATION

PRECAUTIONS PRIOR TO INITIAL STARTING

Before starting the alternator set for the first time the unit should be inspected as follows:

1. Check electrical connections to load. Refer to the electrical connection diagrams.
2. Remove cover surrounding alternator. Turn rotor manually and visually inspect for sufficient clearance between rotating and stationary parts.
3. Check gearbox oil level.

ALIGNING ALTERNATOR WITH TRACTOR POWER TAKE-OFF

The double universal joint construction of the power take-off drive shaft allows for considerable angular misalignment between the gearbox and the tractor power take-off shaft. As shown in Figure 4 the angular misalignment of the universal joints if at all possible should not be more than 15 degrees. If the power take-off drive shaft is taken apart make certain the drive shaft universal joint knuckles are in time with one another as shown in Figure 5. If the drive shaft universal joint knuckles are not in time chattering will occur which will cause a flicker in the electrical output. The same flicker will also occur if the angle of the drive shaft from the alternator to the tractor power take-off shaft lock pin is properly engaged and the removable power take-off shaft shields are installed before operating the unit.

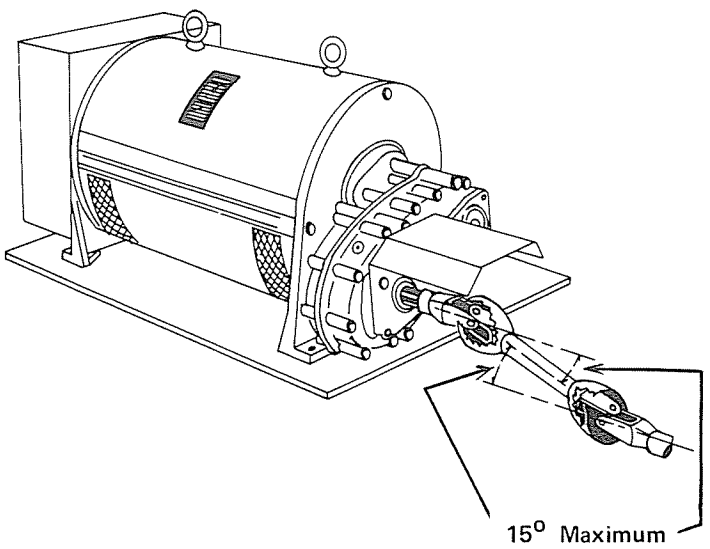

FIGURE 4 TRACTOR DRIVE ALTERNATOR CONNECTED TO TRACTOR POWER

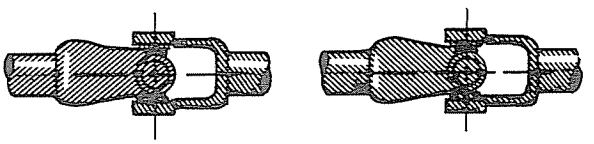
OPERATING ALTERNATOR

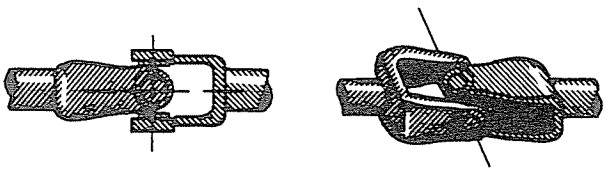
1. Make certain load does not exceed alternator rating and is connected properly. Refer to Figures 2 and 3.
2. Make certain unit is at rated speed and generating desired voltage. Proceedures for adjusting indicator light and voltage are contained in the following paragraphs. Speed may dip slightly when load is applied and, therefore, tractor throttle setting with full load applied may have to be increased slightly from no-load setting.
3. Make certain gearbox has sufficient grease. Fill with EP 90 Gear Oil to slightly below check plug.
4. When the generator is started in extremely cold weather, start the tractor and with the tractor idling, engage the power take-off and let the clutch out slowly. Make certain the gearbox and alternator rotor turn freely.

CAUTION
Do not run at idle speed more than one minute.

Running alternator underspeed could result in damage to voltage regulator and alternator.



RIGHT Universal Joint Knuckles in same plane (Parallel)



WRONG Universal Joint Knuckles NOT in same plane (NOT Parallel)

FIGURE 5 ALIGNING POWER TAKE-OFF SHAFT UNIVERSAL JOINTS FOLLOWING DISASSEMBLY AND REASSEMBLY OF POWER TAKE-OFF SHAFT

HOW TO SET COMBINATION FREQUENCY AND VOLTAGE INDICATOR (LIGHT)

This indicator should be checked for proper setting when the unit is operated for the first time. Adjust as follows:

1. Remove the cover from the terminal box cover. The potentiometer which controls the light is located on the light assembly mounted in the upper left hand corner of the terminal box.

2. Connect an AC Voltmeter to the alternator output (load) lines.

3. Start unit and bring up to alternator shaft speed of 1800 RPM. Check with accurate hand tachometer held on the alternator shaft where it protrudes through the gear case or hold tachometer on alternator shaft at terminal box end of machine.

4. Turn voltage adjust located on regulator assembly to point where desired voltage is indicated on voltmeter.

5. Observe if indicator light is on. If it is not on, turn light adjust potentiometer until light comes on. If light is on, turn light potentiometer until light comes on. If light is on, turn light potentiometer until light goes off and then turn it slowly back to point where light comes back on.

CHECKING ALTERNATOR FREQUENCY WITH AN ELECTRIC CLOCK

Alternator frequency can be checked with an electric clock instead of a tachometer as follows:

1. Plug an electric clock with second hand into 115 volt receptacle.

2. Check sweep of electric clock second hand with sweep of second hand on wrist or pocket watch.

3. If frequency is 60 cycles per second the second hand on the electric clock will move at the same rate as the second hand on watch.

4. If the alternator is underfrequency (underspeed) the electric clock second hand will move slower than the second hand on the watch. If the alternator is over-frequency the clock second hand will move faster than the second hand on the watch.

5. Set engine throttle to point where second hand on the electric clock moves at the same speed as the second hand on the watch.

VOLTAGE ADJUSTMENT

Two potentiometers are included which provides a means of adjusting output voltage, the Auto Voltage Adjust Potentiometer and Voltage Range Adjust Potentiometer. Adjustment when required should be made as follows:

1. Make certain generator is at rated speed of 1800 RPM (60 cycles per second output frequency).

2. Turn Auto Voltage Adjust until desired voltage is indicated on voltmeter, or if combination voltage and frequency light has been set turn Auto Voltage Adjust to point where light comes on.

3. If desired voltage cannot be obtained by turning Auto Voltage Adjust also turn Voltage Range Adjust.

STABILITY ADJUST R8

This resistor controls system stability and response of the voltage regulator. It was set at the factory and generally should not need further adjustment. Only adjust Stability Adjust R8 if instability or slow response occurs during operation.

Turning Stability Adjust clockwise increases negative feedback, therefore increasing stability and response time Stability Adjust should be set so that the output voltage is stable at both no-load and full-load.

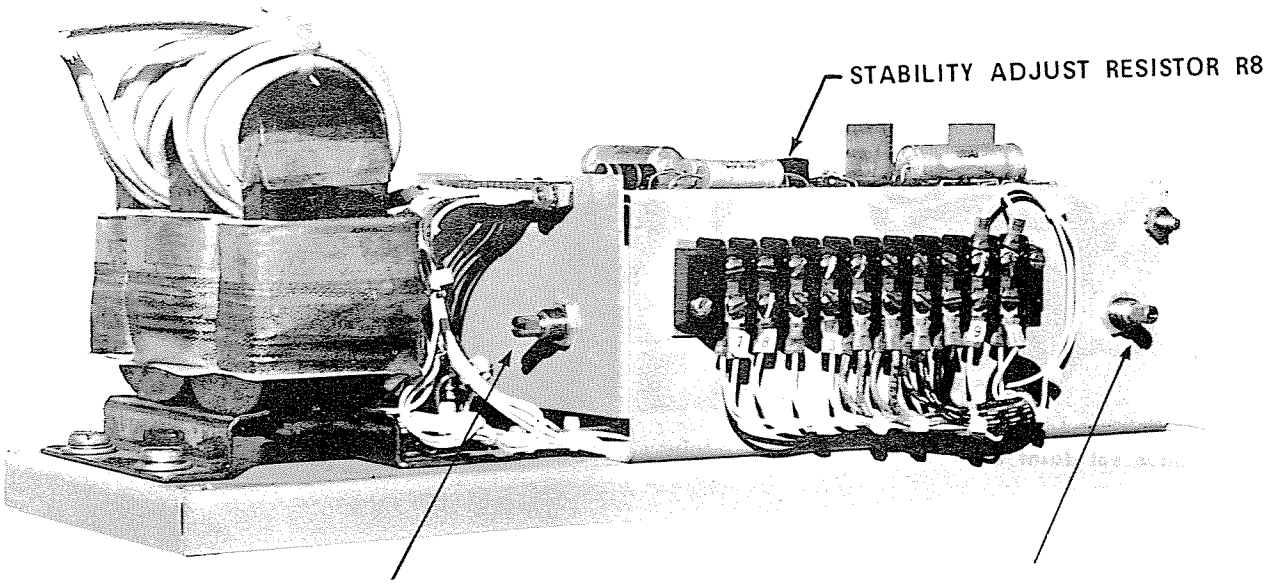


FIGURE 6 VOLTAGE REGULATOR

SERVICE & MAINTENANCE

CLEANING

Do not permit ventilating ports to become clogged. Clean periodically.

GEARBOX LUBRICATION

Periodically check level of oil in gearbox. Maintain oil level slightly below check plug. Use EP 90 Gear Oil.

POWER TAKE-OFF SHAFT LUBRICATION

Periodically lubricate power take-off shaft. Location of grease points are shown in Figure 5.

BEARING LUBRICATION - MODELS 20AVR1 & 28AVR1

Bearings installed in the models listed above are of the shielded ball bearing type. They were factory packed about ½ full of a high quality ball bearing grease. Under normal operating conditions several years of operation can generally be expected before repacking of the bearings is necessary. However, it is difficult to predict bearing or grease life as each application is different. A noisy bearing can be a sign of either a worn bearing or lack of grease.

If bearings are to be repacked, remove shield from bearing and completely clean remaining lubricant from bearing and bearing housing. Carefully inspect beargin for any signs of wear. Repack bearing approximately ½ full using a high quality ball bearing grease. Grease should be capable of withstanding temperatures to 250°F. Where use in cold weather is required, the grease should lubricate satisfactorily at the lowest ambient temperature.

BEARING LUBRICATION - MODELS 40AVR1/55AVR1

The bearings in the models 40AVR1 and 55AVR1 require periodic replenishment of grease. Grease fittings are installed in bearing housing. The generator outlet box cover must be removed for access to the grease fitting. Under normal operating conditions add about ½ ounce of a high quality ball bearing grease once every 7200 hours of operation or once every 20 months, whichever occurs first. Do not overfill. Stop filling when grease beings to drain from internal parts of alternator.

Grease used should withstand temperatures to 250° F. Where use in cold weather is required, the grease should lubricate satisfactorily at the lowest ambient temperature.

REPLACING BEARINGS

Replacement bearings must be of the same size as originally installed at the factory. The following procedures must be followed:

1. If the bearing requires replacement, the terminal box and alternator endbell must be removed. In order to accomplish this, wiring within terminal box must be disconnected.

2. Replacement bearing must be positioned on the shaft so that bearing inner ring is against the bearing shoulder on the shaft.

3. Bearing should be removed with a puller that applies pressure to the bearing inner ring.

4. Bearings are a press fit on the shaft. Replacement bearing should be heated to 220°to 250 degrees F. in clean, temperature controlled oven before attempting to install them on the alternator shaft.

5. A replacement bearing should be installed on the shaft while it is hot as described above. A sleeve or pipe that applies pressure to the bearing inner ring may be used to tap the bearing into place on the shaft. The sleeve or pipe should never exert pressure on the bearing outer ring.

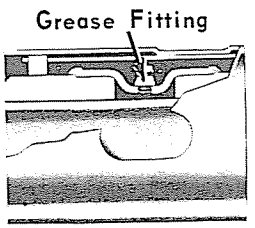
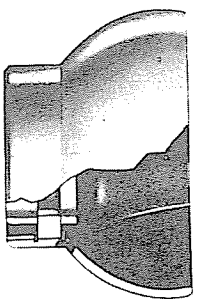
Joint



Tubular Shaft
Partial View



Removable Shield

FIGURE 7 POWER TAKE-OFF SHAFT MAJOR PARTS

TESTING ROTATING RECTIFIERS

Direct current for the alternator field is from the output of rotating rectifiers which are either threaded into the alternator shaft or mounted on a sleeve pressed onto the alternator shaft. They can be tested with a continuity light constructed of two 1½ volt batteries as illustrated in Figure 8.

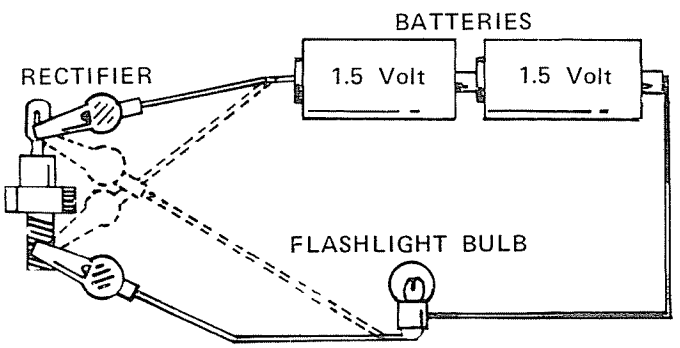


FIGURE 8 TESTING ROTATING RECTIFIERS WITH TEST LIGHT

Test rotating rectifiers as follows:

1. Stop alternator set and remove the cover which surrounds the alternator.
2. Unsolder the wire from the rotating rectifier.

NOTE

When removing lead wire or soldering lead wire back onto the rectifier make certain solder does not drop across rectifier terminal to the case as this would cause rectifier to become shorted.

3. Remove the rectifier from the alternator shaft.
4. Place tester leads across rectifier as shown by solid lines in Figure 8. See if tester bulb lights.
5. Place tester leads across rectifier in the opposite direction as shown by dash lines on Figure 8. See if tester bulb lights.
6. If the tester bulb lights in both steps 4 and 5 the rectifier is probably shorted and should be replaced.
7. If the tester bulb does not light in either steps 4 or 5 it is probably open circuited and should be replaced.
8. Replace any defective rectifiers. Solder lead wires back onto terminal of rectifier and then secure rectifier wires to shaft with tie-down lacing.

VOLTAGE REGULATOR REPAIR OR REPLACEMENT

The function of the voltage regulator is to keep alternator voltage at very near the set value. It does this by changing the amount of field current it supplies the exciter field as the needs of the alternator dictate. An increase in load will normally cause alternator voltage to decrease, the regulator will sense this drop in voltage and supply more field current which will result in restoration of alternator voltage to the set value. A decrease in load will normally cause alternator voltage to rise, the regulator will in this case supply less exciter field current which will result in reduction of alternator voltage to the set value.

Before concluding voltage regulator is defective make certain alternator is at rated speed, voltage adjust potentiometers are set properly and that load does not exceed rating of alternator.

Typical alternator system malfunctions which can generally be attributed to voltage regulator malfunction are:

1. Alternator voltage very low — remains at approximately 25% of rated value at no-load.
2. Alternator voltage high and cannot be controlled by turning the voltage adjust protentiometer or voltage range potentiometer.
3. Alternator output voltage unstable or poor response. Adjustment of Stability Adjust R8 as described in "Operation" section of this manual could correct this defect.

Procedures for testing various components of the voltage regulator are contained in the voltage regulator instruction manual. If failure of components mounted on the printed circuit board occurs replacement of the complete printed circuit board assembly is recommended. If the entire voltage regulator is replaced, make certain replacement regulator is connected properly. Refer to the wiring diagrams contained in the installatin section of this manual.

ALTERNATOR DISASSEMBLY AND ASSEMBLY

Disassembly of alternator can be accomplished as follows:

1. Refer to Figure 1 for part location.
2. Remove bolts securing gear case to alternator. Carefully remove gear case from alternator shaft.
3. Disconnect leads within alternator terminal box. Remove bolts holding terminal box to alternator.
4. Remove bolts holding endbells to alternator frame and stator assembly. Pull endbells.
5. Alternator rotor can be removed from fan end without removing fan.
6. Do not remove exciter field from endbell unless it is to be replaced.

7. Do not remove the alternator bearing if it does not require replacement.

Assembly of the alternator can be accomplished as follows:

1. If a new bearing will be installed refer to preceeding paragraphs titled "Replacing Bearings".
2. If exciter field assembly was removed from endbell install exciter field with lead wires toward endbell.
3. Slide alternator rotor into stator assembly.
4. Install endbells.
5. Install terminal box and reconnect wires. Refer to electrical diagrams contained in the "Installation" section of this manual.
6. Carefully install gear case.

TROUBLESHOOTING

LOCATING TROUBLE

If the alternator does not appear to be producing voltage, check the load circuit breakers or fuses. If a circuit breaker is tripped, reduce the load and reset the breaker. If fuses are blown, replace the fuses. A common cause of poor alternator operation is underspeed. High voltage can be caused by overspeed. Speed can be easily checked with a frequency meter or tachometer.

The following Troubleshooting Chart lists various symproms of poor alternator operation as well as possible causes and means of correcting deficiencies.

TABLE D
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
No Output Voltage	Engine speed too low.	Increase speed until alternator produces 60 cycle.
	Short circuit in load.	Disconnect load. Check motors, appliances and load leads for cause of short circuit.
	Defective receptacles.	Remove terminal box cover & test with test light.
	Loose terminal connections or shorted lead wires in control box.	Remove terminal box cover. Check terminal connections. Check for bare wires.
	Open fuses or circuit breakers.	Replace fuses. Reset circuit breakers.
	Voltage regulator defective.	Contact KATOLIGHT CORPORATION Sales and Service Office, Mankato, Minnesota.
	Open or short circuited leads.	Remove alternator cover and check exciter field leads and leads from exciter armature to rotating rectifiers and alternator field coils. Make certain the tie-down lacing holding exciter leads to shaft is securely wrapped and tied before placing unit back in operation.
	Open or short circuited voltage adjust rheostat or range adjust rheostat.	Check rheostats. Replace if defective.
	Open or short circuited exciter field coils, exciter armature windings, alternator field coils or alternator stator windings.	Consult KATOLIGHT CORPORATION Sales and Service Office, Mankato, Minnesota.

TABLE D TROUBLESHOOTING CHART CON'T.

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Low Voltage	Engine speed too low.	Increase engine speed until alternator produces 60 cycle output.
	Voltage adjust potentiometer not properly adjusted.	Adjust as described in "Operation" section of this manual.
	Alternator Overloaded.	Reduce load to rated value. Make certain alternator is not overloaded by unbalanced load.
	Short circuit in load.	Remove load. Check appliances and motors for point of short circuit.
	Defective voltage regulator or rotating rectifiers.	Consult KATOLIGHT CORPORATION Sales and Service Office, Mankato, Minnesota, if voltage regulator is defective. Test rotating rectifiers.
High Voltage	Engine speed too high.	Decrease engine speed until alternator produces a 60 cycle output.
	Voltage adjust rheostat or range adjust rheostat not set correctly.	Set rheostat. Refer to "Operation" section of this manual.
	Defective voltage regulator.	Contact KATOLIGHT CORPORATION Sales and Service Office, Mankato, Minnesota.
Poor Voltage Regulation	Load in excess of alternator rating.	Reduce load.
Continuous Voltage Fluctuation	Engine speed not constant	Engine may not have enough power or engine governor may be worn or improperly adjusted. Set or repair defective governor.
Vibration & Noise	Defective bearings.	Replace bearing
	Gearbox dry or overfilled.	Check gearbox oil level.
	Power take-off mis-alignment excessive or universal joint dry or worn.	Correct defects. Refer to "Operation" section of this manual for alignment procedures.

FIVE YEAR P.T.O. DRIVEN ALTERNATOR LIMITED WARRANTY

KATOLIGHT warrants to the original purchaser that the product delivered herewith, so far as it has been manufactured, engineered or assembled by KATOLIGHT, is free from defects in material and workmanship, and will perform under normal standby use and service for a period of five years from date of shipment from KATOLIGHT.

KATOLIGHT liability under the warranty specified herein shall be limited to the replacement or repair of the product, at the option of KATOLIGHT, or its authorized service station. This warranty does not apply to accessories supplied, but not manufactured by KATOLIGHT, which in such cases, the original equipment manufacturer's warranty will be applicable. This warranty does not obligate KATOLIGHT to bear the cost of labor or transportation charges in connection with the repair or replacement of defective products, nor shall it apply to a product upon which modifications, repairs or alterations have been made. This warranty shall apply only when the equipment or product has been properly installed, serviced and operated under normal standby conditions, in accordance with the instructions provided for the specific units.

KATOLIGHT shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall KATOLIGHT be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING, BUT NOT LIMITED TO, A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

ALTERNATOR DATA

The alternators described in this manual are 3-phase, 120/240V, 120/208V or 277/480V as specified, 1800 RPM revolving field brushless type with Automatic Voltage Regulation. Output voltage may be varied by turning the voltage adjust potentiometer.

Standard equipment includes: Speed Monitor Light, Automatic Voltage Regulator, Brushless Revolving Field Type Alternator, Mainline Circuit Breaker, 15 Amp, 120 Volt 3 Wire Duplex Receptacle, 50 Amp 240 Volt 4 Wire Receptacle, Full Load Connector, Safety Shield, Lifting Eyes, Helical Gears, Mounting Base, Gear Lube, Grounding Terminal, 1800 RPM Slow Speed, Rodent Screen & Drip Proof Design.

INTRODUCTION

Before any Katolight PTO Driven Alternator is shipped from the factory the alternator is inspected and tested for performance. No unit is shipped unless it produces its rated capacity. Carefully unpack the unit and visually inspect it for damage. If it is damaged, check with the transportation carrier for adjustment of the damage. Before placing the unit in operation, check to make sure that the lubrication is in the gearbox. If empty, remove level check plug and fill with EP90 weight gear oil to check plug level.

If upon installation a new alternator does not work properly, check all electrical connections and the alternator speed before concluding the alternator is defective.

DETERMINING YOUR SPECIFIC LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor which will be operated by the unit. The following chart lists approximate running or operating watts required for various electrical appliances.

TABLE B
APPROXIMATE WATTS REQUIRED
FOR ELECTRICAL APPLIANCES

APPLIANCE	WATTS
Lamp Bulbs	See wattage on bulbs
Radio	40-200
Television	150-300
Vacuum Cleaner	200-750
Automatic Washer	400
Air Conditioner (¾ Ton)	1,250
Refrigerator	325
Food Freezer	300
Furnace (Oil)	700
Deep Well Pump	2,000
Electric Range	600-10,000
Hot Plate (per burner)	600-1,200
Toaster	600-1,130
Water Heater	1,500-5,000
Glow Heater	600-1,200
Heating Pad	40-80
Sun Lamp	250-1,000
Flat Iron	600-1,200
Laundry Dryer	4,750
Electric Heat System	5,000-20,000

Check all appliance nameplates for exact ratings.

HOW ELECTRIC MOTORS ARE CLASSIFIED, AND WHAT THEIR RATINGS MEAN

Electric motors require more current (amperes) starting than running. Split-phase motors are difficult to start and require 5 to 10 times as much current to start as to run, dependent on the NEMA code letter rating. Capacitor motors require 2 to 4 times as much current to start as to run. Repulsion Start Induction Motors require 1½ to 2½ times as much current to start as to run.

The chart below shows the approximate current required to run and start 120 volt, 60 cycle, NEMA Code F induction motors under average load conditions.

Horse Power	Running Amperes	Starting Amperes
1/6	4.4	7 to 15
1/4	5.8	10 to 15
1/3	7.2	15 to 25
1/2	9.8	20 to 30
1	16.0	40 to 50

The NEMA code letter assigned by the motor manufacturer will govern the starting (locked rotor) current surge. The chart below shows the NEMA code letters and their corresponding range of multipliers for the starting current requirement in amperes.

NEMA Code letter Motor Rating	Kilovolt-Amperes per Horsepower (Locked Rotor)
A	0 – 3.14
B	3.15 – 3.54
C	3.55 – 3.99
D	4.0 – 4.49
E	4.5 – 4.99
F	5.0 – 5.59
G	5.6 – 6.29
H	6.3 – 7.09
J	7.1 – 7.99
K	8.0 – 8.99
L	9.0 – 9.99
M	10.0 – 11.19
N	11.2 – 12.49
P	12.5 – 13.99
R	14.0 – 15.99
S	16.0 – 17.99
T	18.0 – 19.99
U	20.0 – 22.39
V	22.4 – and up

Here is a formula for amps:

The starting current for 1 h.p. Code F 230 V.A.C.

1 x 5.6 = 5.6 KVA inrush

$$\text{Amp} = \frac{\text{KVA}}{\text{Volts}} = \frac{5.6^{10^3}}{230} = 24.3 \text{ amp inrush or starting}$$

Because the heavy surge of current required for starting motors is needed only for an instant, the alternator will not be damaged if it can bring the motor up to speed in a few seconds. If difficulty is experienced in starting motors, turn off all other electircal loads and, if possible, reduce the load on the electric motor.

NOTE

IN APPLICATIONS WHERE SEVERAL MOTORS ARE TO BE STARTED, EXCESSIVE OVERLOAD MAY BE AVOIDED BY STARTING THEM ONE AT A TIME. START THE MOTOR THAT REQUIRES THE HIGHEST RUNNING AND STARTING CURRENT FIRST.

INSTALLING THE ALTERNATOR

Provide sufficient ventilation. Do not operate tractor driven alternator in a non-ventilated area. Do, however, provide protection from heavy snow or dust which may plug air cleaners and ventilation openings.

For best operation the following factors should be taken into consideration:

1. Dirt – Dust particles and dirt can cause excessive wear, not only to bearings but to all rotating parts of the alternator.

2. Moist or wet conditions are hazardous. In addition, all electrical equipment should be protected from excessive moisture which deteriorates insulation and causes short circuits.

The generator must be stored properly. Protect it from moisture and dirt. If the unit is to be left in the open, it should be covered whenever it is not in use. All ventilating openings should be cleaned periodically and kept clear and open while operating.

MOUNTING THE ALTERNATOR

The alternator must be solidly bolted to a foundation, platform or bed of a trailer. All four feet on the alternator must contact the foundation or trailer bed. If space is left between a mounting foot and the foundation or trailer, shim it to take up the space and then insert and tighten bolts.

ALIGNING ALTERNATOR WITH TRACTOR POWER TAKE-OFF

The double universal joint construction of the power take-off drive shaft allows for considerable angular misalignment between the gearbox and the tractor power take-off shaft. As shown in Figure 1 the angular misalignment of the universal joints, if at all possible, should not be more than 15 degrees. If the power take-off drive shaft is taken apart, make certain the drive shaft universal joint knuckles are in time with one another as shown in Figure 2. If the drive shaft universal joint knuckles are not in time chattering will occur which will cause a flicker in the electrical output. The same flicker will also occur if the angle of the drive shaft from the alternator to the tractor power take-off is more than 15 degrees. Make certain the power take-off shaft lock pin is properly engaged and the removable power take-off shaft shields are installed before operating the unit.

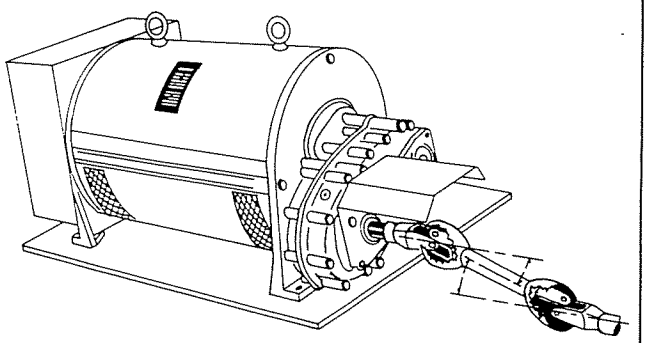

FIGURE 1 - TRACTOR DRIVE GENERATOR CONNECTED TO TRACTOR POWER TAKE-OFF

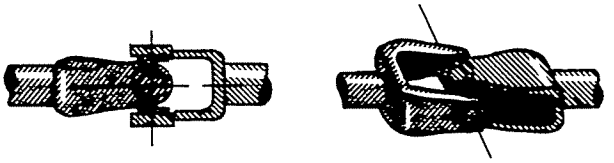
CORRECT Universal Joint Knuckles in same plane. (Parallel)



INCORRECT Universal Joint Knuckles NOT in same plane (Not Parallel)

FIGURE 2 - ALIGNING POWER TAKE-OFF SHAFT UNIVERSAL JOINTS

CONNECTING ALTERNATOR TO LOAD

* Load can be taken from recepticals or by connecting the Alternator into an existing service through the full load connector plug.
* Load taken from recepticals should not exceed the respective receptical rating and should never exceed the alternator rating. The 120 VAC duplex receptical is rated for 15 amps and the 240 VAC receptical is rated at 50 amps. Both recepticals and the full load plug are protected by individual overload protection circuit breakers.
* Load taken from the 240 VAC full load cord set should not exceed the full load rating of the alternator.
* When the Alternator is connected into an existing service normally supplied by commercial power an approved TRANSFER SWITCH MUST BE USED. Check your local electrical code requirements before you make any connections.

INSTALLING GROUND WIRE

Ground the Alternator frame and Neutral leg to a solid earth ground. The ground wire should not be smaller than the load line. A ground stud terminal is supplied for this connection.

GEARBOX LUBRICATION

Check oil level. Fill with EP 90 Gear oil if necessary. Maintain oil level slightly below check plug. DO NOT OVERFILL. Overfilling will cause heating and seal damage.

LAST CHECK BEFORE STARTING THE ALTERNATOR

Before starting the alternator for the first time, the unit should be inspected as follows:

1. Check electrical connections to load. (Refer to the electrical connection diagrams.)

2. Remove cover surounding alternator. Turn rotor manually and visually inspect for foreign objects that may have gotten into the unit during shipping and/or uncrating.

3. Check gearbox oil level.

4. Check alignment of PTO shaft.

5. Make sure all protective covers and guards are in place.

OPERATING THE ALTERNATOR

1. Open the mainline circuit breaker or make sure the transfer switch is "Not" in the emergency position. Starting the alternator with the load applied is not recommended.

2. Start Tractor and Engage PTO.

3. Make certain unit is at rated speed and producing desired voltage. Procedures for reading monitor light and voltage are contained in the following paragraphs. Speed may dip slightly when load is applied and therefore, tractor throttle setting with full load applied may have to be increased slightly from no load setting. The load can now be applied to the alternator by closing the mainline circuit breaker or by transfering the transfer switch into the emergency position.

4. Speed Monitor. When the alternator is being driven at proper speed (1800RPM), the Green light on the Speed Monitor will come on. At 1800 RPM, the alternator puts out 60 Hertz (60 cycles per second). The Green light goes off and the upper or lower red light comes on if the speed is too high or too low. The Green light stays on as long as the alternator output is between 59 and 62 Hertz.

   Motors will run satisfactorily if power frequency is within 5% of their nameplate value, as far as torque and heating are concerned. But note that on induction motors and synchronous motors, speed varies in proportion to frequency, hence any equipment that depends on frequency for timing will not be accurate if alternator speed is off.

5. Using the Speed Monitor.

   a. When starting up the power plant, watch the Speed Monitor.

   b. While the unit is coming up to speed, the bottom RED light will come on; continue to increase speed until the Green light comes on.

   c. After load is applied, it may be necessary to readjust entire speed.

   d. Check the Speed Monitor periodically while the unit is in operation, especially after adding or taking off load. If the top red light comes on, reduce speed; if the bottom red light comes on, increase speed.

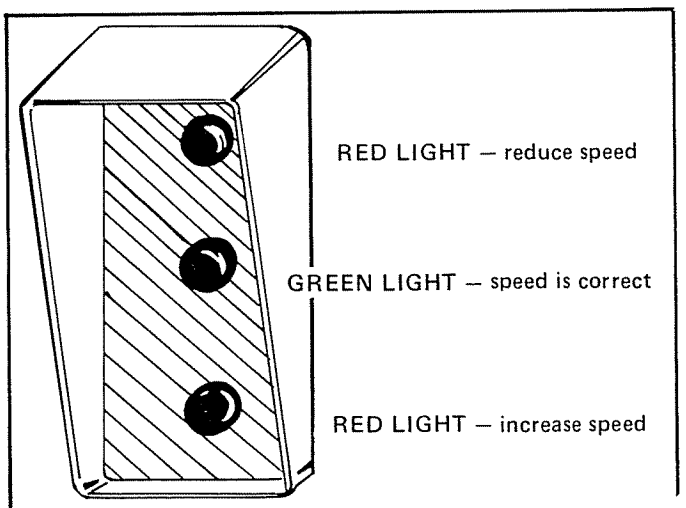


FIGURE 3 - SPEED MONITOR DRAWING

6. When the alternator is used in extremely cold weather, start the tractor and with the tractor idling, engage the power take-off and let the clutch out slowly. Make certain the gearbox and alternator rotor turn freely.

7. FINAL CAUTION:
   DO NOT OPERATE TRACTOR IN NON-VENTILATED AREA.

   STOP TRACTOR BEFORE FILLING WITH FUEL.

   IN APPLICATIONS WHERE ALTERNATOR IS CONNECTED TO SERVICE WHICH IS NORMALLY SUPPLIED BY COMMERCIAL POWER, INSTALL A TRANSFER SWITCH. THIS PRECAUTION PROTECTS PERSONNEL SERVICING COMMERCIAL POWER LINES.

   AVOID CONTACT WITH ALTERNATOR VOLTAGE. WHENEVER MAKING ELECTRICAL CONNECTIONS OR REPAIRING ALTERNATOR, FIRST STOP UNIT.

CHECKING ALTERNATOR OUTPUT VOLTAGE

To check the voltage, use a good quality AC Voltmeter—inexpensive meters often have an error of 10% or more. For best results, choose a meter that will indicate the desired voltage at about ¾ of full scale. For example: to read 240 volts AC, use a 0 to 300 volt AC meter.

On the alternators described in this manual, the line-to-neutral voltage (line 1 [L1] to neutral [N] or L2 to neutral) is one half of the line-to-line voltage (L1-L2). If the two line-to neutral voltages are not equal, it could be due to unbalanced load, a grounded wire, a bad connection, or to a defect in the stator windings.

For personal safety, connect the meter to the generator before starting the engine.

WARNING: DANGEROUS VOLTAGES ARE PRESENT IN THIS UNIT!

ALTERNATIVE METHOD OF CHECKING FREQUENCY

Alternator frequency can be checked with an electric clock and a watch. They should have sweep second hands. Plug an electric clock into the 120 volt receptacle on the alternator. If the second hand on the electric clock moves at the same rate as the second hand on the watch, generator frequency is correct. If the clock lags behind the watch, engine speed is too low; if the clock moves ahead of the watch, the engine is running too fast.

VOLTAGE REGULATOR FUNCTION

Unless the alternator's output voltage is kept within narrow limits, equipment that is powered by it may not operate properly and may be damaged. Motors are usually designed to run satisfactorily only when the voltage at their terminals is within 10% of the nameplate value. In particular, motors will have their torque reduced and will overheat if they are operated at too low a voltage. If the voltage is too high it will cause some devices to burn out.

The purpose of the voltage regulator is to keep the alternator voltage at very near its set value. It does this by supplying the proper amount of direct current to the exciter field, according to the needs of the alternator. An increase in load normally causes the alternator voltage to decrease; the regulator senses this drop in voltage and increases the exciter field current just enough to bring the voltage back up. A decrease in load has the opposite effect—it causes the alternator voltage to go up; the voltage regulator senses this and reduces exciter field current so as to bring the alternator voltage back down to the set value.

The voltage regulator has an adjustment for setting the alternator voltage. This voltage is set at the factory and should require no further adjustment. However, should conditions exist which cause voltage output to change, voltage adjustment can be made with a screwdriver. Refer to the voltage regulator manual for instructions on voltage adjustment, regulator service, etc.

VOLTAGE REGULATOR REPLACEMENT

If the voltage regulator is defective it is advisable to replace the entire circuit board assembly. To reconnect properly, refer to the wiring diagram in the installation section. All connections are made at the terminal strip on the regulator.

EXCITER FIELD VOLTAGE

When there is a problem with the alternator, it is often useful to check the Voltage Regulator output to the exciter field. This voltage can be read at terminals F+ and F— on the regulator. The values should be taken from units running at rated speed (1800 rpm) and rated output voltage (240 VAC) with NO LOAD. Exciter field voltage will normally be higher at no load than when the alternator is loaded. Note that DC meters are required to measure the exciter field voltage and current. Polarity must be observed.

ELECTRICAL SERVICE AND MAINTENANCE

TESTING THE ROTATING RECTIFIER OR DIODE

A rotating rectifier changes the AC that is generated in the exciter armature to DC which is required for the alternator field. The rotating rectifier consists of six individual rectifier diodes. Each individual diode has two terminals. The diodes are threaded into the sleeve shaft of the exciter armature; this makes it possible to test the rectifier diodes with a 3 volt

DC test lamp as shown in Figure 4. Figure 4 shows the test being made with the diode removed entirely from the circuit. It is possible, however, to test the rectifier without disassembling it.

1. Stop the alternator and remove the cover from the outlet box.

2. The connection between the alternator field and the exciter armature can be seen on the exciter armature: the wires are bolted together, covered with an insulating sleeve, and bound to the armature with nylon wraps. Note the position of this connection so that it can be restored properly later. Cut and remove the wraps, being very careful not to damage the armature; remove the sleeve and open the connection.

3. Test each diode as shown in Figure 4.

   a. Open diode. If any diode does not pass current as it should, replace it. Refer to the paragraph on Removing and Installing Diodes.

   b. Shorted diode. If one of the diodes is shorted, it will be difficult to identify it without unsoldering the diode connections. If a short is indicated, unsolder and test diodes one by one until the shorted diode is found.

4. After making sure that good diodes are installed, restore all connections. For securing the alternator field connection, obtain plastic tie wraps similar to the ones installed at the factory and be careful not to damage the armature winding when tying down the wires.

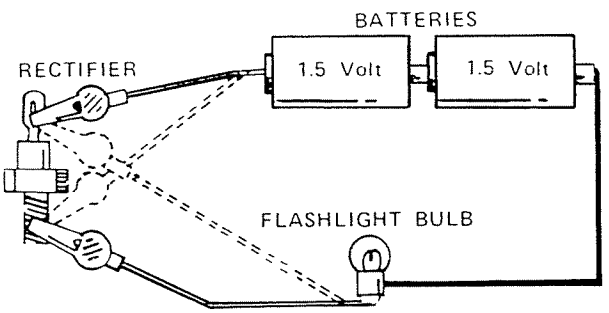

FIGURE 4 - TESTING ROTATING RECTIFIERS WITH TEST LIGHT

REMOVING AND INSTALLING DIODES

The diodes are rugged and will easily withstand the stresses of normal operation, but they can be damaged during removal or installation unless it is done carefully.

1. Do not try to turn the diode without first unsoldering it, since a twisting force on the solder terminal could damage the diode internally.

2. When soldering or unsoldering, do not use any more heat than necessary. The diode can be protected from excessive heat by applying a clip-on heat sink or a long-nosed pliers on the terminal between the soldering iron and the body of the diode.

3. Do not use excessive force when screwing the diode into its mounting. Considerably less force is required here than in tightening bolts of similar size.

RESTORING RESIDUAL MAGNETISM

The cores of the alternator and exciter fields retain a certain amount of magnetism after the power plant has been shut down. This residual magnetism must be present to begin the voltage build-up process when the power plant is started up again. If residual magnetism is lost due to a long idle period or some other cause, it will be necessary to flash the field. This is done by connecting a 12-volt battery across the exciter field for 15-30 seconds. Proceed as follows:

1. Disconnect the two exciter field leads from voltage regulator terminals F+ and F—. The field leads should be marked F2 and F1. See Figure 5.

2. *Disconnect regulator power leads from the voltage regulator.

3. Connect the negative terminal of a 12 volt battery to lead F1.

4. Connect the positive terminal of the battery to lead F2 for a few seconds.

5. Start the engine and bring the unit up to speed.

6. There should be voltage at the alternator output—up to 200 volts AC line-to-line, more or less. If there is still no voltage, contact your local factory representative.

7. If voltage is now present, shut down the unit, disconnect the battery and connect the exciter field to the voltage regulator, F2 to F+ and F1 to F—.

8. Reconnect * regulator power leads.

9. Start up the engine and bring it up to speed; check output voltage.

* Refer to the voltage regulator manual for regulator connections, regulator operation, etc.

FIGURE 5

CAUTION! Exercise extreme caution at all times. Insulate or isolate all AC leads. They are extremely hazardous. Do NOT touch them or allow them to touch anything!

Approximate AC output voltage using 12 volt DC battery as exciter field power.

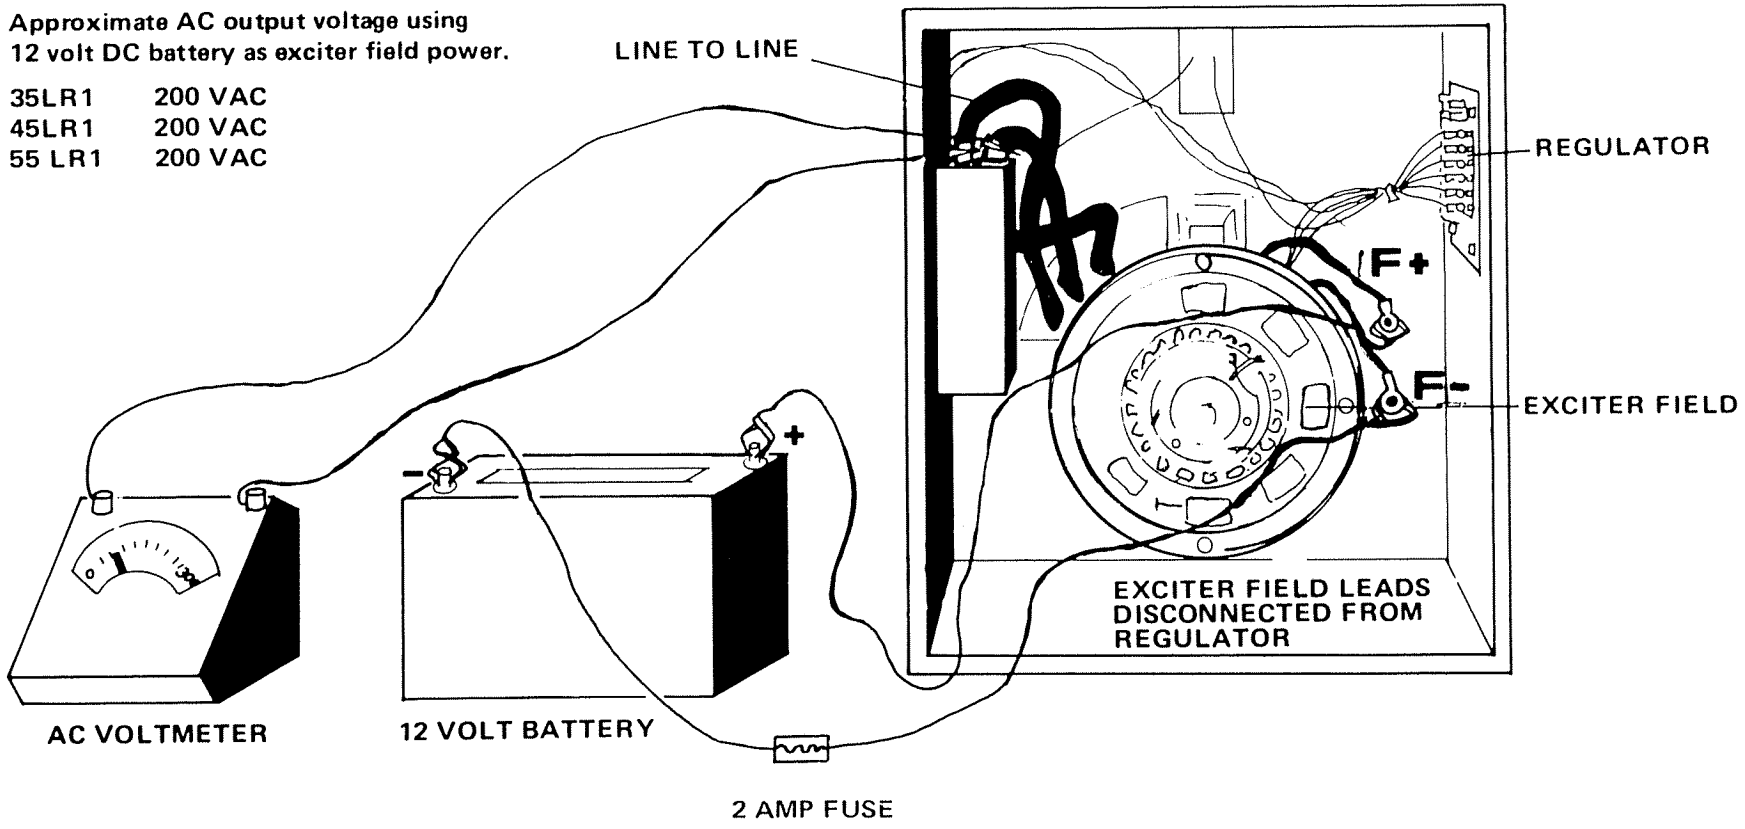
45LR1	200 VAC
55 LR1	200 VAC



MECHANICAL SERVICE AND MAINTENANCE

CLEANING

Do not permit ventilating ports to become clogged. Clean periodically.

REPLACING BEARINGS

Replacement bearings must be of the same size as originally installed at the factory. These procedures must be followed.

1. If the bearing requires replacement, the terminal box and alternator endbell must be removed. In order to accomplish this, wiring within terminal box must be disconnected.

2. Replacement must be positioned on the shaft so that bearing inner ring is against the bearing shoulder on the shaft.

3. Bearings should be removed with a puller that applies pressure to the bearing inner ring.

4. Bearings are a press fit on the shaft. Replacement bearing should be heated to +220° to +250° F. in a clean, temperature controlled oven before attempting to install them on the alternator shaft.

5. A replacement bearing should be installed on the shaft while it is hot as described above. A sleeve or pipe that applies pressure to the bearing inner ring may be used to tap the bearing into place on the shaft. The sleeve or pipe should never exert pressure on the bearing outer ring.

ALTERNATOR DISASSEMBLY AND ASSEMBLY

Disassembly of alternator can be accomplished by following these steps.

1. Refer to cutaway drawing for location of parts.

2. Remove bolts securing gear cases to alternator. Carefully remove gear case from shaft. A jaw type puller may be required on older units.

3. Disconnect leads within alternator terminal box. Remove bolts holding terminal box to alternator.

4. Remove bolts holding endbells to alternator frame and stator assembly. Pull endbells.

5. Remove exciter armature by disconnecting leads. (Carefully cut ties holding leads to exciter armature windings).

6. Generator rotor can be removed from fan end without removing fan.

7. Do not remove exciter field from endbell unless it is to be replaced.

8. Do not remove bearings if they do not require replacement.

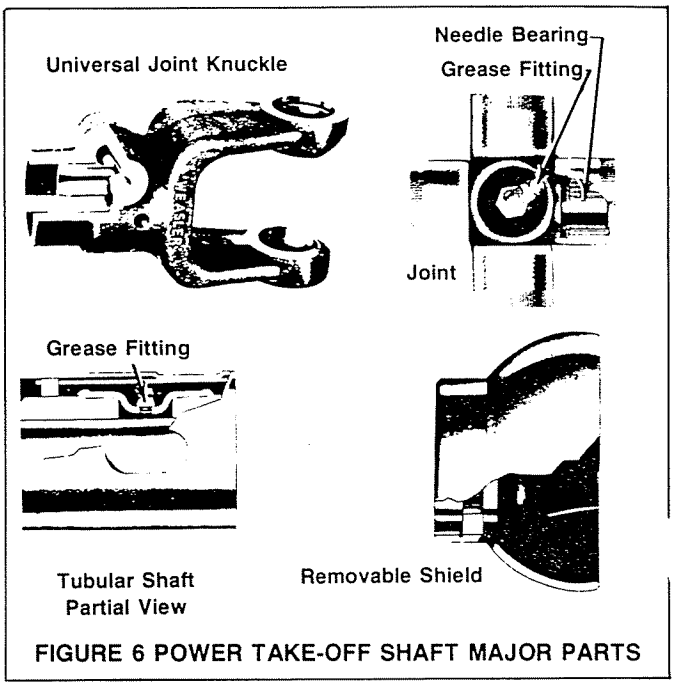


FIGURE 6 POWER TAKE-OFF SHAFT MAJOR PARTS

Assembly of the alternator can be accomplished by following these steps:

1. If new bearings are to be installed refer to preceeding paragraphs titled Replacing Bearings.

2. If exciter field assembly was removed from end bell, install exciter field with lead wires toward endbell.

3. Slide alternator rotor into stator assembly.

4. Install endbells.

5. Install terminal box and reconnect wires. Refer to electrical diagrams contained in the Installation Section of this manual.

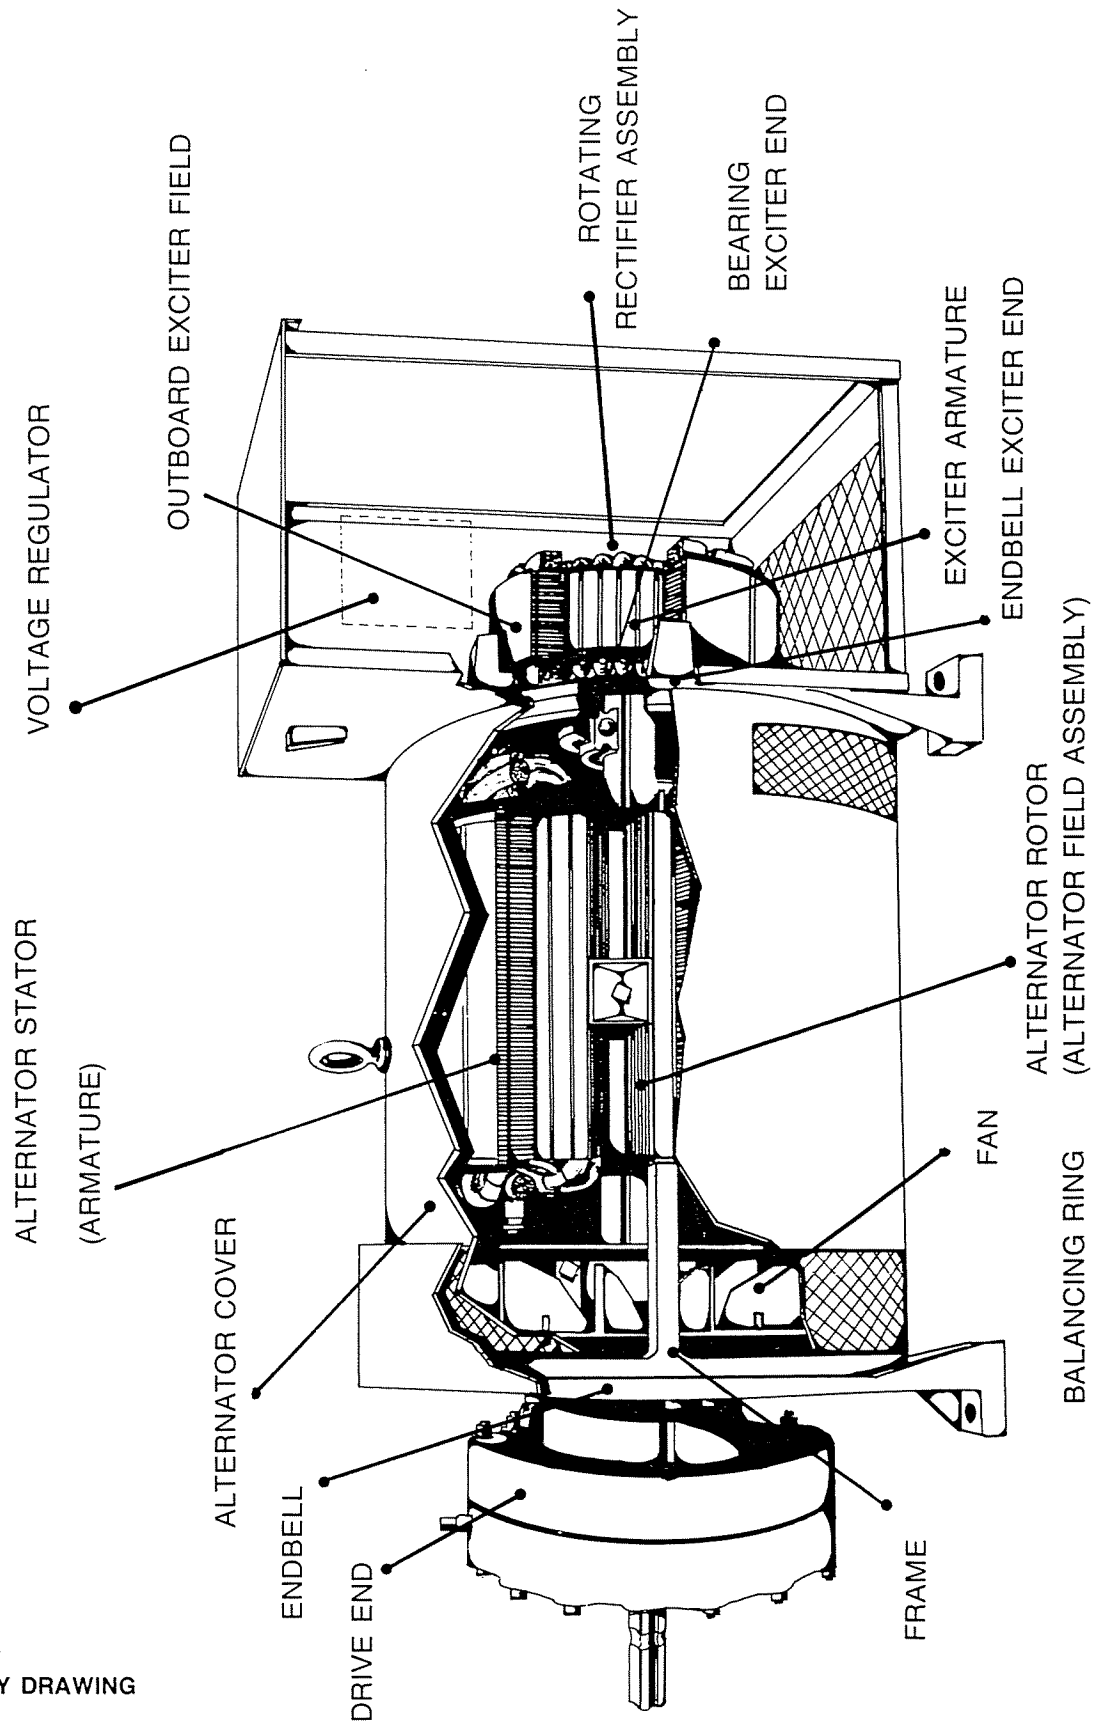

FIGURE 7
CUTAWAY DRAWING

LOCATING TROUBLE

If the alternator does not appear to be producing voltage, check the load circuit breakers or fuses. If a circuit breaker is tripped, reduce the load and reset the breaker. If fuses are blown, replace the fuses. A common cause of poor alternator operation is underspeed. High voltage can be caused by overspeed. Speed can be easily checked with a frequency meter or tachometer.

The following Troubleshooting Chart lists various sympto of poor alternator operation, possible causes and means of correcting deficiencies.

TABLE C
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
No Output Voltage.	Engine Speed too low.	Increase speed until alternator produces 60 cycles.
	Short Circuit in load.	Disconnect load. Check motors, appliances and load leads for short circuit.
	Open fuse on voltage regulator.	Check fuse on voltage regulator. If burned open install new fuse of same voltage.
	Defective receptacles.	Remove terminal box cover and test with test light.
	Loose terminal connections or shorted lead wires in control box.	Remove terminal box cover. Check terminal connections. Check for bare wires.
	Open fuses or circuit breakers.	Replace fuses. Reset circuit breakers.
	Voltage regulator defective.	Contact KATOLIGHT CORPORATION Sales and Service Office—Mankato, MN.
	Open or short circuited leads.	Remove alternator cover and check exciter field leads. Check leads from exciter armature to rotating rectifiers and alternator field coils. Make certain the tie down lacing holding exciter leads to shaft is securely wrapped and tied before placing unit back in operation.
	Open or shorted voltage adjust rheostat.	Check rheostat.
	Open or short circuited exciter field coils exciter armature windings, alternator field coils or alternator stator windings.	Consult KATOLIGHT CORPORATION Sales and Service Office—Mankato, MN.

CONTINUED

TABLE C
TROUBLESHOOTING CHART CONTINUED

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Low Voltage	Engine speed too low.	Increase engine speed until alternator produces 60 cycle output.
	Voltage adjust rheostat not properly adjusted.	Adjust to rating.
	Alternator Overloaded.	Reduce load to rated value. Make certain alternator is not overloaded by unbalanced load.
	Short circuit in load.	Remove load. Check appliances and motors for point of short circuit.
	Defective voltage regulator or rotating rectifiers.	Consult KATOLIGHT CORPORATION Sales and Service Office —Mankato MN if voltage regulator is defective. Test rotating rectifiers.
High Voltage	Engine speed too high.	Decrease engine speed until alternator produces a 60 cycle output.
	Voltage adjust rheostat not set correctly.	Adjust to proper voltage.
	Defective voltage regulator.	Contact KATOLIGHT CORPORATION Sales and Service Office—Mankato MN.
Poor Voltage Regulation	Load in excess of alternator rating	Reduce load. Check nameplate rating.
	Wrong alternator speed or defective regulator.	Correct speed. Replace Regulator.
Continuous Voltage fluctuation	Engine speed not constant	Engine may not have enough power or engine governor may be worn or improperly adjusted. Set or repair defective governor.
	Defective Regulator.	Replace Regulator.
Vibration & Noise	Defective bearings	Replace bearings
	Gearbox dry or overfilled.	Check gearbox oil level.
	Power take-off misalignment excessive or universal joint dry or worn.	Correct defects. Refer to Operation section of this manual for alignment procedures.
	Loose mounting bolts	Check or tighten as necessary

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order:

1. Always give SERIAL NUMBER, and MODEL NUMBER.
2. Give the item part number and description. Give the quantity required of each item. DO NOT ORDER BY REFERENCE NUMBER OR GROUP NUMBER. If an old part cannot be identified return the part POSTAGE PREPAID to your distributor or KATOLIGHT CORPORATION. Write a letter to the same address stating the reason for returning the part.

Five Year P.T.O. Driven Alternator Limited Warranty

KATOLIGHT warrants to the original purchaser that the product delivered herewith, so far as it has been manufactured, engineered or assembled by KATOLIGHT, is free from defects in material and workmanship, and will perform under normal standby use and service for a period of five years from date of shipment from KATOLIGHT.

KATOLIGHT liability under the warranty specified herein shall be limited to the replacement or repair of the product, at the option of KATOLIGHT, or its authorized service station. This warranty does not apply to accessories supplied, but not manufactured by KATOLIGHT, which in such cases, the original equipment manufacturer's warranty will be applicable. This warranty does not obligate KATOLIGHT to bear the cost of labor or transportation charges in connection with the repair or replacement of defective products, nor shall it apply to a product upon which modifications, repairs or alterations have been made. This warranty shall apply only when the equipment or product has been properly installed, serviced and operated under normal standby conditions, in accordance with the instructions provided for the specific units.

KATOLIGHT shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall KATOLIGHT be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING, BUT NOT LIMITED TO, A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

Alternator
LSA 41.1, 41.2, 42.1, 44.1 - 4P

1 - GENERALITES

1.1 - Spécifications

Alternateurs auto excités par bobinages auxiliaires à caractéristiques "compound" sans bague, ni balais avec régulateur automatique de tension.
Ils sont conformes à la plupart des normes internationales et en particulier aux suivantes :

- C.E.I : recommandations de la Commission Electrotechnique Internationale (34-1)
- U.T.E : normes françaises de l'Union technique de l'Electricité (NFC 51-111, 105, 110 ...)
- V.D.E : normes Allemandes Verein Deutscher Elektrische Ingenieure (0530)
- B.S.S : normes britanniques British Standard Specification (4999, 5000)
- NEMA : MG 21 norme américaine

Caractéristiques mécaniques (machine standard)
- Carcasse en acier
- Flasques en fonte
- Roulements à billes étanches (graissés à vie)
- Forme de construction standard :

B 34 (bipalier à pattes et bride de fixation à trous taraudés) Bout d'arbre cylindrique normalisé.
MD 35 (monopalier à disque et bride d'accouplement)
- Machine ouverte, autoventilée
- Degré de protection : IP 21 (IP 23 sur demande)

(Alternateur en rotation)

Conditions normales de fonctionnement (machine standard)
- Altitude inférieure à 1000 m
- Température ambiante inférieure à 40° C
- Facteur de puissance compris entre 0,8 AR et 1

Limite de fonctionnement dangereux
- Survitesse : 25 % pour 60 Hz (2250 min^{-1})
- Marche à plus de 110 % de la tension nominale
- Surcharges (voir tableau de puissances)

Caractéristiques
- Isolation classe H
- Capacité de surcharge : les alternateurs sont capables de faire démarrer des moteurs electriques dont le courant de démarrage est de l'ordre de 3 fois le courant nominal de l'alternateur .
- Régulation de tension : de l'ordre de ± 1% en régime établi à la vitesse nominale sur charge triphasée non déformante équilibrée; sur charge monophasée ou déséquilibrée la régulation de tension peut atteindre ± 5%.
- Amorçage automatique sur la tension rémanente.

1.1.1 - Désignation

1 - GENERAL

1.1 - Specification

Brushless alternators self excited by auxiliary windings acting as a booster, self regulated by an automatic voltage regulator.
They comply with the following international standards:

- I.E.C : recommendations of the Intertnational Electrotechnical Commission (34-1)
- U.T.E : French standards of the Union Technique de l' électricité (NFC 51-111 - 105 - 110 ..)
- V.D.E : German standards Verein Deutscher Elektrische Ingenieure (0530)
- B.S.S : British Standard Specification (4999, 5000)
- NEMA : MG 21 american standard

Mechanical features (standard machine)
- Steel frame
- Cast iron end shields
- Sealed for life ball bearings
- Standard construction features :

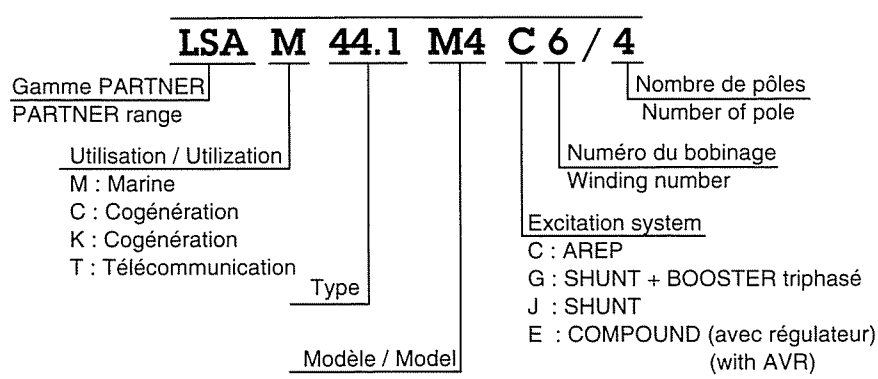
Shape B34 (foot and flange mounted) cylindrical normalized shaft end
MD 35 (Single bearing, flange and disc coupling)
- Machine screen protected / self ventilated
- Mechanical protection : IP 21 (IP 23 optional)

Normal operating conditions (Standard machine)
- Altitude : less than 1000 m (3300 ft)
- Ambient temperature : less than 40° C
- Power factor : from 0,8 lagging up to unity.

Limits for safe operation
- Overspeed : 25% for 60 Hz (2250 RPM)
- Working at up 110% of rated voltage
- Overloads : (see power table and curves)

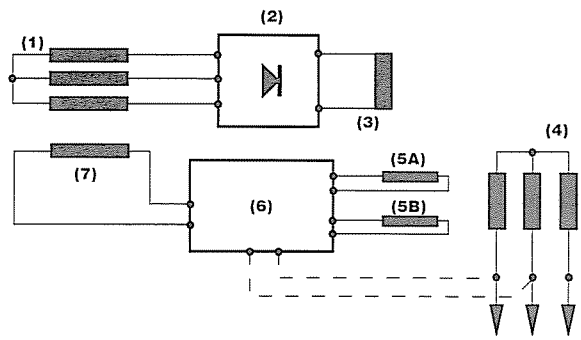
Electrical features
- Insulation class H
- Overload capacity : the alternator is able to start electric motors, the starting current of which is about 3 times the rated current of the alternator.
- Steady state voltage regulation in the order of ± 1% at rated speed when supplying non distorting three phase balanced loads. With single phase (or unbalanced) loads voltage regulation is about ± 5%.
- Voltage build up based on residual magnetism.

1.1.1 - Designation



1.2 - Principe de fonctionnement

Le régulateur de tension est alimenté par 2 bobinages auxiliaires, l'un des bobinages (5A) a une caractéristique shunt(tension proportionnelle à la tension alternateur), l'autre (5B) une caractéristique série (tension proportionnelle au courant du stator).
Lors du démarrage, grâce au rémanent de l'excitatrice, il se crée un courant dans l'induit de l'excitatrice (1). Ce courant, redressé par les diodes tournantes (2) alimente la roue polaire (3). Celle-ci induit une tension dans le bobinage stator de l'alternateur (4) (tension de sortie) ainsi que dans le bobinage auxiliaire (5A).
La tension induite dans le bobinage auxiliaire alimente à travers le régulateur (6) l'inducteur de l'excitatrice (7).
Le régulateur de tension (6) contrôle le courant d'excitation de l'excitatrice en fonction de la tension de sortie de l'alternateur. En charge, surcharge ou court circuit le bobinage auxiliaire (5B) fournit un surcroit d'excitation (effet booster).



1.2 - Principle of operation

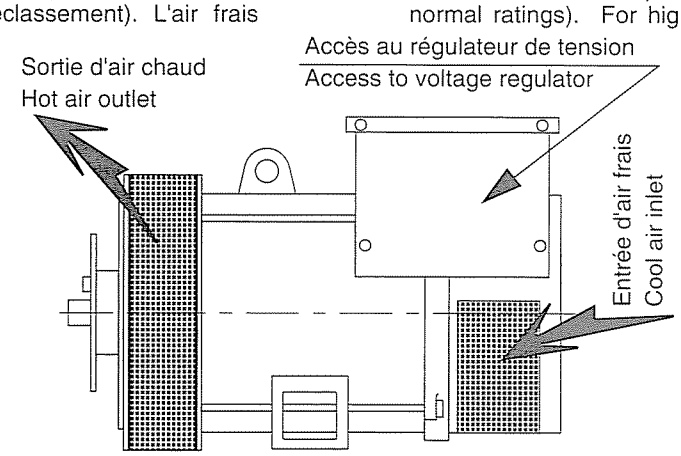
The AVR is fed by 2 auxiliary windings located in the stator. One of the windings (5A) with shunt characteristic (delivering a voltage proportional to the generator's output voltage) and the second one (5B) with a series characteristic (delivering a voltage proportional to the generator's output current).
When starting the residual magnetism creates a current in the exciter armature(1). This current is rectified by the rotating diodes (2) and feeds the main field (3).
The induced voltage in the auxiliary winding (5A) is then used to increase the excitation power via the AVR (6) to the exciter field (7) to ensure a rapid and smooth build up of output voltage in the main stator winding (4).
The voltage sensing for the AVR is taken from the output leads (phase V-W). On load, overload or short circuit the auxiliary winding (5B) supplies an additional excitation voltage (boosting effect).

2 - INSTALLATION

A la réception de votre alternateur, verifier l'état de la machine. S'il y a des dégats apparents , contacter le transporteur.

2.1 - Emplacement - Ventilation

Le local dans lequel est placé l'alternateur doit être tel que la température ambiante ne puisse dépasser 40°C pour les puissances standard (pour des températures > 40°C, appliquer un coéfficient de déclassement). L'air frais exempt d'humidité et de poussière, doit parvenir librement aux grilles d'entrée d'air situées côté opposé à l'accouplement. Il est nécessaire d'empêcher autant que possible le recyclage de l'air chaud sortant côté accouplement, ou de l'air chaud provenant du moteur thermique, ainsi que des gaz d'échappement.
Avant l'installation
Veiller à retirer les papiers de protection disposés lors de la peinture de la machine dans les ouvertures.



2 - INSTALLATION

Unpack the alternator, check for any damage to the crate pallet or plywood shipping container. If any damage is visible, it is possible the alternator itself has been damaged. This damage should be reported to the shipping carrier.

2.1 - Location - Ventilation

The room in which the alternator is installed shall be such that the ambient temperature never exceeds 40°C (at normal ratings). For higher ambients a derating factor should be applied.
Fresh air, free of humidity and dust, must circulate easily through the screen at the non drive end of the alternator. The recycling of heated air, from the D.E. or circulating from the prime mover, should be avoided as far as possible. Ensure adequate ventilation for a good air flow at all times.
Precautions to be taken before installation
Make sure air inlet and outlet openings are clear.

2.2 - Vérifications électriques

Avant la mise en fonctionnement, il est recommandé de vérifier l'isolement de la machine entre phase et masse et entre phases. Le régulateur doit être debranché pour cette opération. Celle ci s'effectue à l'aide d'un mégohmètre (500 volts continu). L'isolement doit être normalement > **10 mégohms** à froid.

ATTENTION . Il est formellement proscrit de mettre en service un alternateur neuf ou non, si l'isolement est inférieur à 1 mégohm pour le stator et 100 000 ohms pour les autres bobinages.
On peut trouver des valeurs inférieures en cas de stockage ou d'arrêt prolongé, si la machine est utilisée dans une zone

2.2 - Electrical checks

Before putting the machine into service, an insulation check between phase and earth and between phase is recommended. For this operation the A.V.R. must be deconnected. This one is carried out by means of a "megger" 500 V.d.c. Insulation should be > **10 meghoms**.

CAUTION : No machine whether new or used should be operated if insulation is less than 1 meghom for stator and 100 000 ohms for other windings.

If lower, the machine must be dried until the minimum value is obtained.

LEROY SOMER
Katolight Service - Master Repair Manual - Page 240

à forte hygrométrie (bord de mer, régions tropicales) ou bien soumise à des projections d'eau, d'embruns etc...
Pour retrouver les valeurs minimales ci dessus, plusieurs méthodes sont possibles.
a) Déshydrater la machine pendant 24 heures dans une étuve à une température d'environ 110 °C
b) Insuffler de l'air chaud dans l'entrée d'air en assurant la rotation de la machine inducteur déconnecté
c) Fonctionner en court-circuit (déconnecter le régulateur de tension)
- court-circuiter les trois bornes de sortie (puissance) par des connexions capables de supporter le courant nominal (ne pas dépasser si possible 6 A/mm2)
- installer une pince ampèremétrique pour contrôler le courant passant dans les connexions du court-circuit.
- brancher aux bornes des inducteurs de l'excitatrice, en respectant les polarités, une batterie de 48 Volts, avec en serie, un rhéostat d'environ 10 ohms (50 Watts).
- ouvrir au maximum tous les orifices de l'alternateur : boite à bornes, grilles de protection, etc.
- mettre en rotation l'alternateur à sa vitesse nominale et régler son excitation au moyen du rhéostat de manière à obtenir l'intensité nominale dans les connexions du court-circuit.
Nota : Arrêt prolongé
Pour éviter les difficultés exposées ci-dessus, l'utilisation de résistances de réchauffage ainsi qu'une rotation d'entretien périodique sont recommandées. (Les résistances de réchauffage ne sont réellement efficaces que si elles sont en fonctionnement permanent pendant l'arrêt de la machine.)

To get to the minimum value, there are several methods:
a) Bake the machine for 24 hours in an oven at about 110°C
b)Dry out the machine with a stream of hot air.
c) Disconnect the voltage regulator
- short-circuit the three output (power) terminals through connections capable of carrying the rated current (if possible do not exceed 6 A/mm2)
- with an appropriate ammeter, monitor the current flowing in the short circuited connections.
- connect a 48 volt storage battery to the field winding terminals of the exciter (respecting polarities), fitted in series with a rheostat of about 10 ohms (250 Watts).
- open completely all the apertures of the alternator : terminal box panels, protection screens etc .....
- start up the machine at its rated speed and adjust its excitation through the rheostat in order to obtain the rated current in the short-circuited connections.

Note : lengthy down-times
In order to avoid such troubles, it is recommended to fit anti condensation heaters or to run the machine periodically. (During the long down time, the anti condensation heaters must operate full time.)

2.3 - Vérifications mécaniques

2.3.1 - Sens de rotation

L'alternateur fonctionne correctement dans les 2 sens de rotation.
Le sens de rotation standard est le sens horaire vu coté bout d'arbre (rotation des phases 1 - 2 - 3). Pour un sens de rotation anti-horaire, la rotation des phases 1 - 2 - 3 s'obtient en permutant 2 et 3.

2.3.2 - Alternateur bipalier

- Accouplement semi-élastique
Il est recommandé de réaliser un alignement soigné des machines en vérifiant que les écarts de concentricité et de parallélisme des 2 demi-manchons n'excèdent pas 0,1 mm.
ATTENTION :
Cet alternateur a été équilibré avec 1/2 clavette.
- Entraînement par poulies courroies
Vérifier avec soin le parallélisme des arbres et l'alignement des poulies. La tension des courroies ne doit pas être éxagérée afin de ménager les roulements de l'alternateur.
La charge radiale maximale admissible au milieu du bout d'arbre indiquée dans le tableau est celle qui correspond à une durée de vie calculée "L10" de 20000 H à 1800 min^{-1}.

2.3 - Mechanical checks

2.3.1 - Direction of rotation

The alternator can be driven in either direction of rotation but standard phase rotation is 1 - 2 - 3 , when rotation is clockwise viewed on the drive end.
For anti-clockwise rotation transpose phase 2 and 3.

2.3.2 - Two bearing alternator

- Semi-flexible coupling
Careful alignment of the machines by measuring the concentricity and parallelism of the two parts of the coupling is recommended. The difference between the readings shall not exceed the specified values (say 0.1 mm).
WARNING :
This generator has been balanced with an half key .
- Belt and pulley drive
Carefully check for both correct shaft parallelism and pulley alignment. The tension of the belt should not be so high as to cause strain-on the alternators bearings.
Maximum radial load allowable on the middle of standard shaft extension for a bearing service life L 10 of 20 000 hours at 1800 min^{-1} is as follow .

Type	Roulements - Bearings (*)		Charge radiale max
	Avant / D.E.	Arrière / N.D.E.	Max radial pull
LSA 41.1	6309 . 2RS/C3	6308 . 2 RS/C3	350 da.N (780 lbs)
LSA 41.2	6310 . 2RS/C3	6308 . 2 RS/C3	350 da.N (780 lbs)
LSA 42.1	6310 . 2RS/C3	6308 . 2 RS/C3	350 da.N (780 lbs)
LSA 44.1	6313 . 2RS/C3	6310 . 2 RS/C3	520 da.N (780 lbs)
LSA 44.1L7L	6314 . 2RS/C3	6310 . 2 RS/C3	520 da.N (780 lbs)
LSA 44.1L8L	6314 . 2RS/C3	6310 . 2 RS/C3	520 da.N (780 lbs)

(*) Tous les roulements sont lubrifiés avec une graisse haute température.

(*) All bearings are lubricated with a hight temperature grease.

Nota : Dans des cas spéciaux d'accouplement par poulies-courroies (ou les données ne seraient pas celles indiquées ci-dessus) , veuillez consulter le bureau d'études (Usine de Sillac).

2.3.3 - Alternateur monopalier

Avant d'accoupler les deux machines, vérifier leur compatibilité par :
- une analyse torsionnelle de la ligne d'arbre
- un contrôle des dimensions du volant et carter de volant, de la bride, des disques et déport de l'alternateur. Après accouplement vérifier l'existence du jeu latéral du vilbrequin.

3 - MISE EN SERVICE

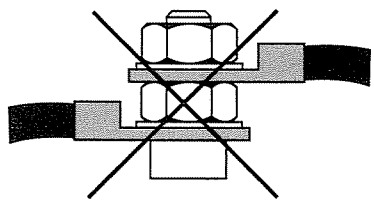
3.1 - Vérifications préliminaires

3.1.1 - Vérifications mécaniques

Avant le premier démarrage, vérifier que :
- les boulons de fixation des pattes et de la bride sont bien bloqués,
- l'air de refroidissement est bien aspiré et refoulé par les ouies de la machine sans obstacle,
- les grilles et carter de protection sont bien en place,
- pour les alternateurs monopaliers, le couple de serrage des disques d'accouplement est de :
  - 3,8 m.daN = LSA 41.1
  - 10,4 m.daN = LSA 41.2, 42.1,44.1.

3.1.2 - Vérifications électriques

Vérifier que :
- un dispositif de coupure différentielle, conforme à la législation sur la protection des personnes en vigueur dans le pays d'utilisation, a bien été installé sur la sortie de puissance de l'alternateur au plus près de celui-ci.



- le raccordement de la machine au réseau a bien été réalisé cosse sur cosse et que les écrous des bornes sont bien bloqués,
- le raccordement des câbles et barrettes éventuelles est conforme au schéma joint à la machine,
- les protections éventuelles ne sont pas déclenchées,
- dans le cas d'un régulateur extérieur,les connexions entre l'alternateur et l'armoire sont bien éffectuées selon le schéma de branchement,
- il n'y a pas de court-circuit entre phase ou phase-neutre entre les bornes de sortie de l'alternateur et l'armoire de contrôle du groupe électrogène (partie du circuit non protégée par les disjoncteurs ou relais de l'armoire).

3.1.3 - Vérifications électriques du régulateur
- Vérifier que toutes les connexions sont bien réalisées selon le schéma de branchement joint.
- Vérifier que le strap de selection de fréquence "ST3" est sur la bonne valeur de fréquence.
- Vérifier si le strap ST4 ou le potentiomêtre extérieur sont raccordés.
- Fonctionnements optionnels
• Strap ST1 : coupé pour raccordement du module de détection triphasé R 730.
• Strap ST2 : coupé pour temps de réponse rapide.
• Strap ST5 : coupé pour supprimer la fonction LAM.

Note : In certain cases of special belt coupling (where the data would not be those mentioned above), please consult our Sillac plant.

2.3.3 - Single bearing alternator

Before coupling the two machines, make sure of their compatibility by :
- torsional analysis
- check all dimensions of flywheel and flywheel housing and flange, discs and spacing.
After coupling, check lateral play of crankshaft.

3 - STARTING UP

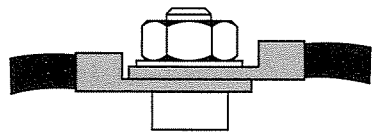
3.1 - Preliminary checks

3.1.1 - Mechanical checks

Before starting up
- that all foot and flange bolts are tightened
- that the cooling air circulates freely around and through the machine,
- check that all louvres, guards, etc .... are correctly fitted
- for single bearing alternators the discs are fastened to the coupling hub with bolts torqued at :
  - 3,8 m.daN = LSA 41.1
  - 10,4 m.daN = LSA 41.2, 42.1, 44.1.

3.1.2 - Electrical checks

Check that :



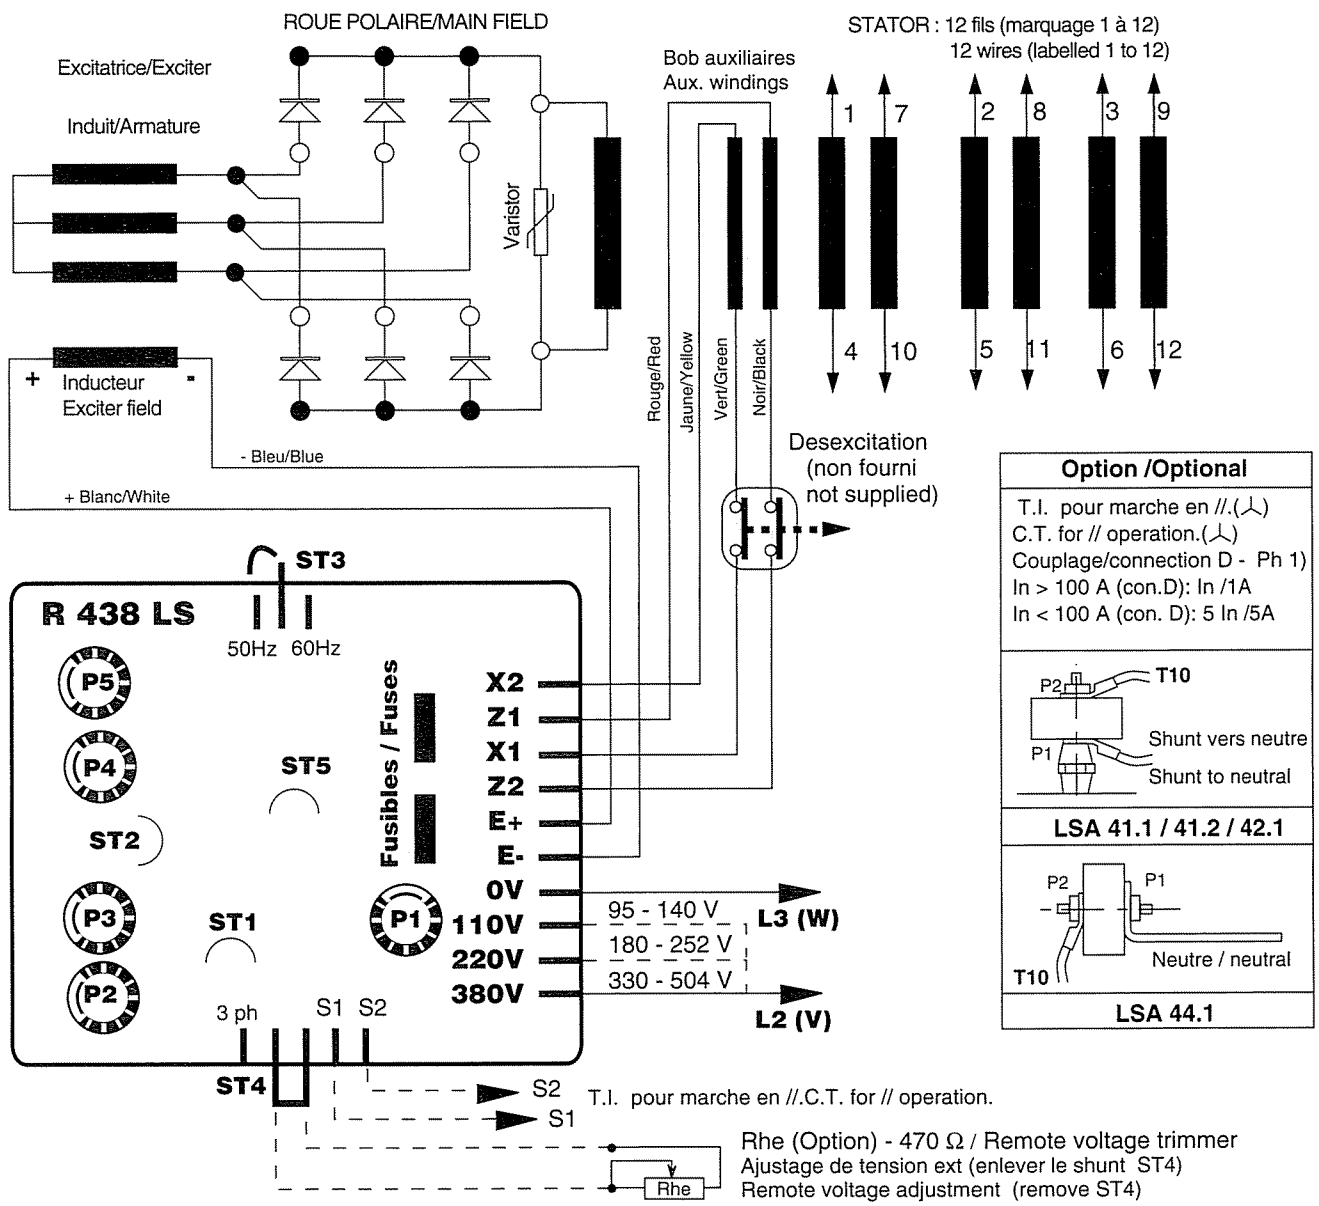
- a suitable electrical protection device is fitted in the output circuit for safety reasons (in line with the codes of practice in force within the country where the alternator is installed)
- the machine-to-power supply interconnection is made according to the drawing (terminal lugs adjacent to each other). Ensure before start up that terminal nuts are properly tightened.
- the terminal links correspond to the voltage required
- the control panel protection equipment is correctly set
- for separately fitted regulator, that the connections between alternator and panel correspond to wiring diagram,
- that there is no short-circvuit due to fautly connections either LL. or L.N between the terminals of the alternator and the power switch or breaker (this part of the circuit is not protected by the breaker)

3.1.3 - AVR electrical checks

Ensure all connections are according to attached diagrams
- Check frequency selection jumper "ST3".
- Check if jumper ST4 or remote potentiometer are connected.
- Optional operating modes selection:
• Link ST1 : cut for connection of 3 phase sensing module R730.
• Link ST2 : cut for fast voltage recovery.
• Link ST5 : cut to eliminate LAM action.

3.2 - Schéma des connexions internes

3.2 - Internal connection diagram



P1 : Statisme - Quadrature voltage droop
P2 : Tension - Voltage
P3 : Stabilité - Stability
P4 : Seuil de sous-vitesse - Frequency threshold + LAM
P5 : Plafond d'excitation / Excitation current ceiling
ST1 : Détection standard monophasée - Single phase voltage sensing ⌒
ST2 : Temps de réponse - Recovery time: normal ⌒ Rapide -Fast ⌒⌒
ST3 : Fréquence - Frequency selection
ST4 : Potentiomètre extérieur - Remote trimmer
ST5 : Avec / with LAM ⌒ sans / without LAM ⌒⌒
Fusibles / Fuses : 250 V . 6,3 A (rapide / fast)
Option / Optional : Détection triphasée - 3 phase sensing : **ST1** ⌒⌒
(avec module additionnel R 730 - with additional module R 730)

SCHEMA DES CONNEXIONS ET BRANCHEMENT DU REGULATEUR

SCHEMA DES CONNEXIONS ET BRANCHEMENT DU REGULATEUR
WIRING AND A.V.R. CONNECTION DIAGRAM

Extrait du schema / Extracted from N°: 2218.05.92(0)

L'alternateur standard est livré avec 8 barrettes de couplage.
(*) L'usine peut fournir en option un jeu de shunts souples et une barrette de neutre pour réaliser les connexions.

Standard alternator is fitted with 8 coupling plates.
(*) As an option to make these connections, shunts and neutral coupling plate can be provided by factory.

4 - ENTRETIEN

4.1 - Circuit de ventilation

Il est recommandé de veiller à ce que la circulation d'air ne soit pas réduite par une obturation partielle des grilles d'aspiration et de refoulement : boue, fibre,suie, etc ....

4.2 - Roulements

Les roulements sont graissés à vie: durée de vie approximative de la graisse (selon utilisation) = 20 000 heures ou 3 ans. Surveiller l'élèvation de température des roulements qui ne doit pas dépasser 60°C au dessus de la température ambiante. Dans le cas d'un dépassement de cette valeur, il est nécessaire d'arrêter la machine et de procéder à une vérification.

4.3 - Bruits anormaux

- La naissance de bruits et de vibrations inhabituels peut provenir de la détérioration ou de l'usure des roulements. Il est préférable de procéder à leur remplacement, afin d'éviter le risque d'un blocage qui pourrait avoir de fâcheuses répercussions sur l'alternateur.
- Dans le cas d'alternateur monopalier le bruit peut également provenir d'un mauvais alignement.
- Les alternateurs monophasés ou les alternateurs triphasés fonctionnant en régime déséquilibré ainsi que les alternateurs triphasés couplés en zig zag, même sur charge équilibrée sont plus bruyants et ont davantage de vibrations que les machines triphasées en régime équilibré.

4 - MAINTENANCE

4.1 - Cooling circuit

It is recommanded to check that the cooling air circulation is not restricted.

4.2 - Bearings

The bearings are sealed for life
Approximate grease life : 20 000 hours or 3 years
Temperature rise of ball bearings :
Periodically check that the temperature of the bearings does not exceed 60°C above ambient temperature.
If higher, it is necessary to stop the machine and proceed to a general inspection.

4.3 - Abnormal noises

- The generation of abnormal noises and vibrations may result from wear and tear of the ball bearings. It is better to proceed to their replacement so as to avoid any risk of seizure which could seriously damage the alternator.
- In the case of single bearing machines, the abnormal noise may also be caused by misalignment.
- Both single phase alternators and three phase alternators supplying unbalanced loads are more noisy and have more vibrations than three phase machines with balanced loads. The same applies to three phase generator connected in dog - leg, even with 3 phase balanced loads.

4.4 - Pièces de première maintenance

4.4 - Recommended spare parts

Pour éviter toute erreur à la livraison des pièces détachées, veuiller rappeler les indications marquées sur la plaque signalétique, notamment le type et le numéro de la machine ainsi que le repère de la pièce dans la nomenclature.

5 - SERVICE ET DEPANNAGE

5.1 - Vérifications préliminaires :

Si, à la mise en service, le fonctionnement de l'alternateur se révèle anormal, il y aura lieu de vérifier tout d'abord.
- Le branchement des différents éléments suivant le schéma joint à la machine.
- La continuité des liaisons, vérifier la solidité et le bon contact à tous les raccordements.
- La vitesse du groupe (se fier plutôt à un fréquencemètre qu'à un compte tours)
- Vérifier que les protections soient bien enclenchées, etc.....

To avoid errors on delivery of spare parts, all information marked on nameplates shoul be supplied on parts orders, in particular model and serial number of the alternator. Also give the parts numbers from the parts list.

5 - SERVICE AND FAULT FINDING

5.1 - Preliminary checks

When running, if the alternator does not operate correctly, first check:
- That the connections correspond to diagram for the machine.
- That the connections are properly tightened.
- That the running speed of the set is correct (frequencymeter)
- That protection equipment is correctly set.

5.2 - Défauts ayant une manifestation physique extérieure (échauffement,vibrations,bruits)

5.2 - Evident physical defects (overheating, noise,vibrations .....)

	Défaut / Fault	Action	Origine du défaut & Origin of fault
A	Echauffement excessif du ou des paliers (temp > à 80°C sur les chapeaux de roulements avec ou sans bruit anormal)	Démonter les paliers	- Si le roulement a bleui ou si la graisse est carbonisée, changer le roulement. - Cage de roulement mal bloquée (tournant dans son emboîtement) - Mauvais alignement des paliers (flasques mal emboités)
	Excessive overheating of one or both bearings (temp of bearings over 80 °C)(With of without abnormal bearing noise)	*Disassemble bearings*	*- If the bearing has turned blue or if the grease has turned black , change the bearing.* *- Bearing race badly locked (moving in its housing)* *-Bracket misalignment.*
B	Echauffement excessif de la carcasse de l'alternateur(plus de 40° C au dessus de la température ambiante)	Contrôler - les entrées et sorties d'air de l'alternateur - les appareils de mesure (voltmètre, ampèremètre) - temp. ambiante	- Circuit d'air (entrée-sortie) partiellement obstrué ou recyclage de l'air chaud de l'alternateur ou du moteur thermique - Fonctionnement de l'alternateur à une tension trop élevée (> à 105% de Un en charge.) - Fonctionnement de l'alternateur en surchage
	Excessive overheating of alternator frame (temperature 100°F above ambient)	*Check* *-Air inlets and outlets of alternator* *-Measuring equipment (volmeter - ammeter)* *- Ambient temperature*	*- Air flow (Inlet - outlet) partially clogged or hot air is being recycled either from alternator or prime mover* *- Aternator is functionning at too high a voltage (over 105 % of rated voltage on load).* *- Alternator overloaded.*
C	Vibrations excessives	Vérifier l'accouplement et les fixations des machines	- Mauvais alignement (accouplement) - Amortissement défectueux ou jeu dans l'accouplement - Défaut d'équilibrage d'un des éléments de la ligne d'arbre
	Too much vibration	*Check the coupling and the machine mountings*	*Misalignment (coupling)* *- Defective mounting or play in coupling* *- Incorrect balancing of shaft (Engine - Alternator)*
D	Vibrations excessives plus bruit (grognement provenant de l'alternateur)	Arrêter immédiatement le groupe. Vérifier l'installation	- Marche en monophasé de l'alternateur (charge monophasée ou contacteur défectueux ou défaut de l'installation)
		Remettre en marche à vide si le grognement persiste	- Court-circuit dans le stator de l'alternateur
	Excessive vibration and humming noise coming from the alternator	*Stop the gen-set* *Check the installation*	*Three phase alternator is single phase loaded in excess of acceptable level.*
		Start up with no-load : *if humming persists ....*	*- Short-circuit in the alternator stator*

	Défaut / Fault	Action	Origine du défaut & Origin of fault
E	Choc violent, éventuellement suivi d'un grognement et de vibrations	Arrêter immédiatement le groupe electrogène.	- Court-circuit sur l'installation - Faux couplage (couplage en parallèle non en phase) Conséquences possibles (suivant l'importance du défaut) - Rupture ou détérioration de l'accouplement - Rupture ou torsion des bouts d'arbre. - Déplacement et mise en court-circuit du bobinage de la roue polaire. - Eclatement ou déblocage du ventilateur - Destruction des diodes tournantes, du régulateur.
	Alternator damaged by a significant impact which is followed by humming and vibration	*Stop the gen-set immediately*	*- Short-circuit in external circuit* *- Faulty parallel connection (out of phase)* *- Possible consequences (according to the seriousness of the above faults :* *- Break or deterioration in the coupling* *- Break or twist in shaft extension* *- Shifting or short-circuit of the main fieid winding* *- Bursting or unlocking of the fan.* *- Diode burnt, regulator, rectifier bridge damaged*
F	Fumée, étincelles ou flammes sortant de l'alternateur + grognements et vibrations	Arrêter immédiatement le groupe .	- Court-circuit sur l'installation (y compris entre alternateur et disjoncteur) - Objet tombé dans la machine - Court circuit ou flash au stator
	Smoke, sparks, or flames issuing from the alternator	*Stop the set immediately*	*- Short-circuit in external circuit (including wiring between alternator and control board).* *- Object fallen into the machine.* *- Short-circuit or flash in stator winding*

5.3 - Défauts de tension **5.3 - Voltage faults**

	Défaut Defect	Action	Mesure / Measure	Controle
G	Absence de tension à vide au démarrage	Brancher entre E- et E+ une pile neuve de 4 à 12 volts en respectant les polarités	L'alternateur s'amorce et sa tension reste normale après suppression de la pile	- Manque de rémanent - Vérifier la tension E- et E+ (env 6 V) - U > 10 V : défaut diode ou excitatrice
			L'alternateur s'amorce mais sa tension ne monte pas à la valeur nominale après suppression de la pile	- Vérifier le branchement de la référence tension au régulateur - Retoucher le potentiomètre (P2)tension du régulateur
			L'alternateur s'amorce mais sa tension disparaît après suppression de la pile	Défaut du régulateur
				Vérifier le branchement du régulateur (éventuellement régulateur défectueux) -Inducteurs coupés - Diodes tournantes claquées - Roue polaire coupée - Vérifier la résistance
	No voltage at no load or start up	*Connect a battery of 4 to 12 volts to terminals E+ or E- on the A.V.R.*	*The alternator builds up and voltage is correct after battery removal*	*- Lack of residual magnetism* *- Check voltage between E- and E+ of the A.V. R (correct value about 6 v)* *- Fault in rotating diodes* *- U > 10 V exciter faulty*
			The alternator builds up but voltage does not reach nominal value after battery removal	*- Check the connection of the sensing leads to the A.V. R* *- Readjust the potentiometer (P2) voltage*
			The alternator builds up but voltage collapses after battery removal	*- A. V. R failure*
				- Check the connection of the sensing leads to the A.V.R *- Exciter windings shorted or open circuit (check winding)* *- Rotating diodes burnt (check diodes)* *- Main field winding open circuit (check resistance)*

	Défaut Defect	Action	Mesure / Measure	Controle
H	Tension trop élevée	Réglage du potentiomètre tension du régulateur	Réglage inopérent, mesurer la tension entre E+ et E-	- Tension entre E+ et E- > 12 V Défaut du régulateur
	Voltage too high	*Adjust potentiometer voltage*	*No adjustment of voltage, measure voltage between E+ and E- on A.V.R.*	*Voltage between E+ and E- > 12 V* *A.V.R. faulty*
I	Oscillations de la tension	Réglage du potentiomètre stabilité (P2)	Si pas d'effet : essayer les modes normal rapide (ST2)	- Vérifier la vitesse : possibilité irrégularités cycliques - Bornes mal bloquées - Défaut du régulateur
				Vitesse trop basse en charge (ou LAM réglé trop haut) - 1 diode tournante ouverte - Coupure du bobinage auxiliaire du stator - Court-circuit de la roue polaire en charge - Induit défectueux en charge
	Voltage oscillation	*Set potentiometer (P2) Stability*	*If no result : change recovery mode normal / fast (ST2)*	*- Check speed for possible cyclic irregularity* *- Check out put connections* *- Faulty A.V.R.*
				- Speed below nominal on load (or LAM set too high) *- A rotating diode is open circuit* *- Auxiliary winding is open circuit (check resistance values)* *- Short circuit on main field (check resistance)* *- Exciter armature winding faulty (check resistance)*
J (1)	Tension bonne à vide et trop basse en charge	Mettre à vide et vérifier la tension entre E+ et E- sur le régulateur	Tension entre E+ et E- < 6 V	- Vérifier la vitesse (ou LAM réglé trop haut)
			Tension entre E+ et E- > 10 V	- Diodes tournantes défectueuses - Court-circuit dans la roue polaire. Vérifier la résistance - Induit de l'excitatrice défectueux
	Voltage correct on no-load, too low on load	*Run on no-load and check voltage between E+ and E-*	*Voltage between E- and E+ is < 6 V (d.c)*	*- Check speed (or LAM set too high)*
			Voltage between E- and E+ is > 10 V (d.c)	*- Fault in rotating diodes* *- Short circuit in main field , check resistance* *- Exciter armature field faulty (check values)*

(1) Attention : Dans le cas d'utilisation en monophasé, vérifier que les fils de détection venant du régulateur soient bien branchés aux bornes d'utilisation.

(1) Important : In the case of single phase operation, check that the sensing leads are correctly connected to the relevant output leads.

K (2)	Disparition de la tension pendant le fonctionnement	Vérifier le régulateur, la varistance, les diodes tournantes et changer l'élément défectueux	La tension ne revient pas à la valeur nominale	- Inducteurs excitatrice coupés - Roue polaire coupée ou en court-circuit - Induit excitatrice défectueux - Régulateur défaillant
	Voltage collapses during normal operation	*Check the regulator, the surge suppressor, the rotating diodes and replace any defective part*	*The output voltage does not return the nominal value .*	*- Exciter winding faulty (check values)* *- Main field faulty (check values)* *- Regulator faulty* *- Faulty exciter armature*

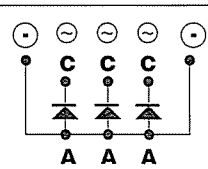
(2) Action possible de la protection interne (surcharge,coupure, court-circuit)

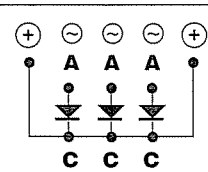
(2) May be due to AVR internal protection (overload, loss of sensing, short-circuit)

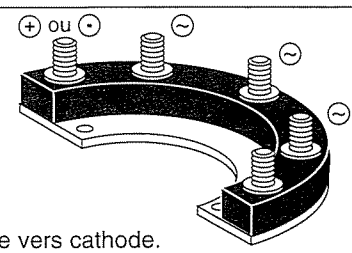
5.4 - Vérification d'une diode tournante

5.4 - Checking a rotating rectifier diode

LSA 41.1, LSA 41.2
Pont de diodes
Rectifiers bridge

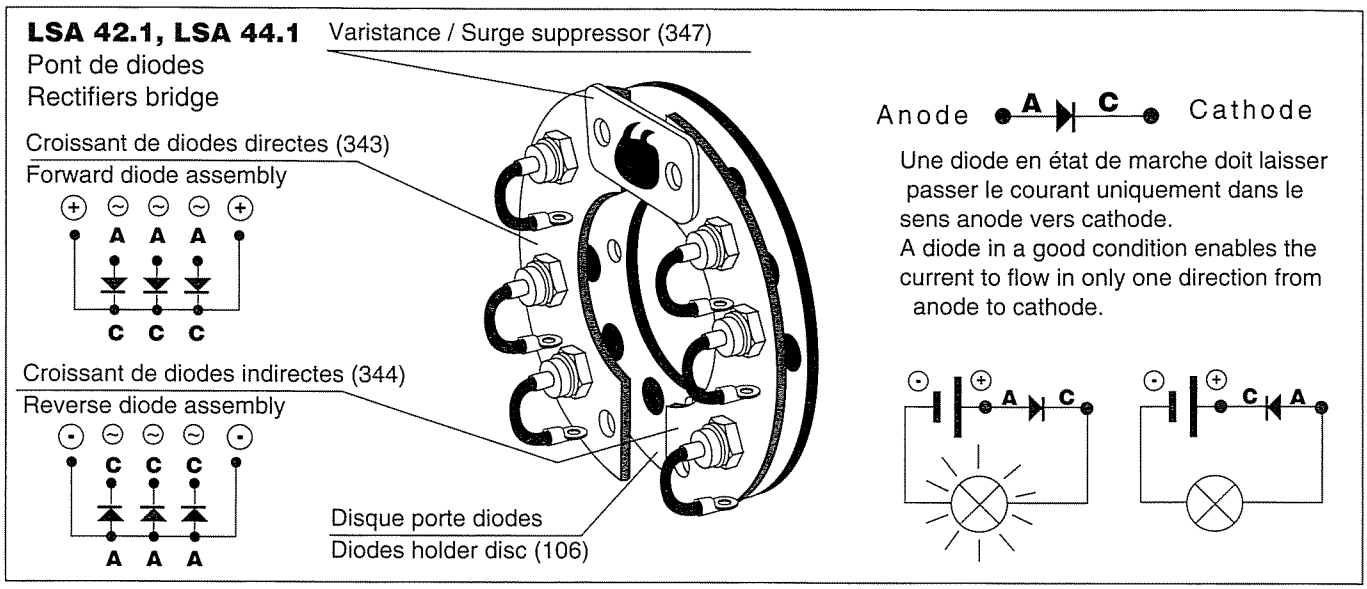






Anode  Cathode

Une diode en état de marche doit laisser passer le courant uniquement dans le sens anode vers cathode.
A diode in a good condition enables the current to flow in only one direction from anode to cathode.



5.5 - Amorçage par excitation séparée

L'alternateur s'amorce seul grâce à l'aimantation rémanente du circuit magnétique de son excitatrice.Pour une première mise en service (en usine) ou après incident, il est nécessaire de réaimanter ce circuit magnétique.
Pour cela il faut brancher une batterie ou une pile de (4-12V) aux bornes de l'inducteur pendant 2 à 3 secondes.
Ne pas dépasser le courant d'excitation nominal. Cette opération s'effectue quand l'alternateur tourne à sa vitesse nominale.

5.5 - Voltage build-up by field flashing (at no load)

The alternator is self exciting from the residual magnetism of the magnetic circuit of the exciter.When first tested (at the factory) this magnetic circuit is magnetized but after a breakdown it may be necessary to remagnetize.
Proceed as follows.
Connect a 4 - 12 V battery to the terminals of the field winding for two or three seconds.
This should be carried out at rated speed.

5.6 - Tableau des valeurs moyennes normales 4 pôles - 50 Hz - (400V pour les excitations)

Les valeurs de tension et de courant s'entendent pour marche à vide et en charge nominale avec excitation séparée. Toutes les valeurs sont données à ± 10% (pour les valeurs éxactes, consulter le rapport d'essai) et peuvent être changées sans préavis.

5.6 - Normal average values - 50 Hz. 4 Pôles (400 V for excitation)

Values of voltages and currents are given for no-load and full rated load operation with separate excitation. All values are within ±10% (for real values consult test report) and may be changed accordingly without notice.

TYPE	Résistance à / at 20°C (Ω)						Excitation - 400 V - 50 Hz

Pour les machines 60 Hz, les valeurs des résistances sont les mêmes. Les valeurs "i exc" sont approximativement de 5 à 10 % moins fortes.
Symboles utilisés :
"i exc": courant d'excitation de l'inducteur d'excitatrice.

For 60 Hz machines, the values of resistance are the same. The values of "i exc" are about 5 to 10 % weaker.
Symbol used :
"i exc" : excitation current in exciter field.

Alternator
LSA 41.1, 41.2, 42.1, 44.1 - 4P

5.7 - Régulateur de tension R 438 LS

ATTENTION : IL EST DANGEREUX DE PROCÉDER A UN ESSAI DIELECTRIQUE SUR L'ALTERNATEUR SANS DÉBRANCHER TOUTES LES LIAISONS AU RÉGULATEUR.

LES DOMMAGES CAUSÉS AU RÉGULATEUR DANS DE TELLES CONDITIONS NE SONT PAS COUVERTS PAR NOTRE GARANTIE.

5.7.1 - Description

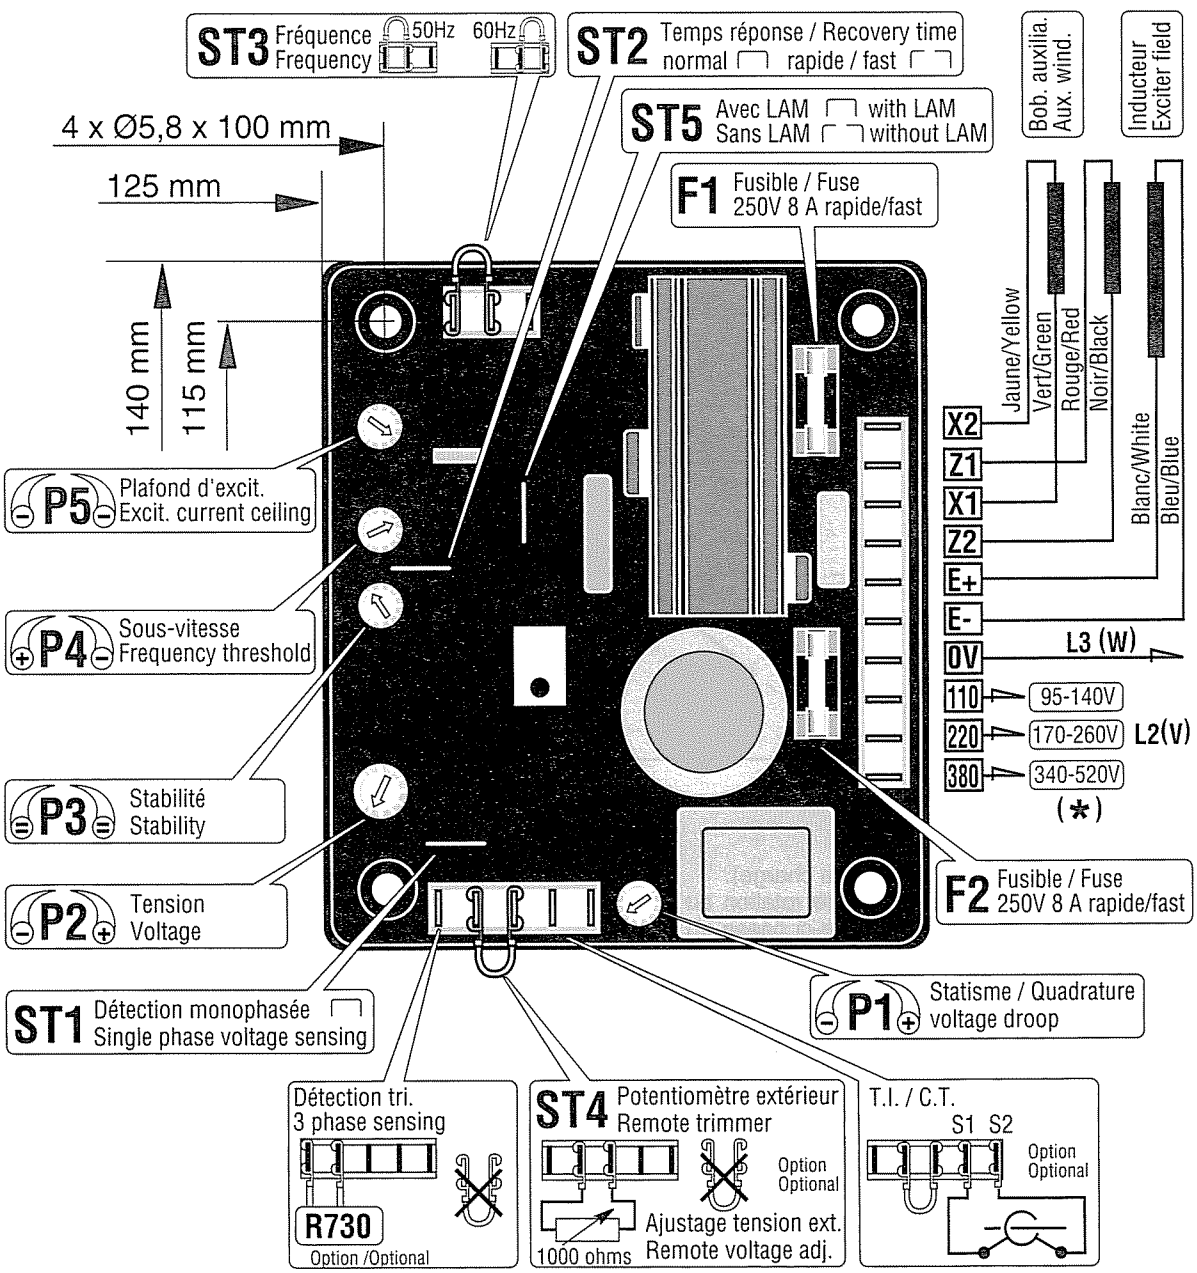
Les composants électroniques montés dans un boitier plastique sont enrobés dans un élastomère opaque. Le raccordement se fait à partir de languettes mâles "Faston" 6,3.

5.7 - Automatic Voltage Regulator R 438 LS

CAUTION : IT IS HAZARDOUS TO PROCEED TO ANY HIGH VOLTAGE TEST ON THE ALTERNATOR WITHOUT HAVING PREVIOUSLY DISCONNECTED ALL CONNECTIONS TO VOLTAGE REGULATOR. DAMAGES OCCURING TO AVR IN SUCH CONDITIONS WILL NOT BE CONSIDERED IN A WARRANTY CLAIM.

5.7.1 - General

The PC board with electronic components is located inside an insulating plastic box and embeded in elastomere resin.Terminals consist in 1/4" "Faston" lugs.



5.7.2 - Caractéristiques

- alimentation standard ; 2 bobinages auxiliaires (X1X2,Z1Z2)
- alimentation shunt ; max 100 à 150V - 50/60 Hz
- courant de surcharge nominal : 8A, 10s
- protection électronique (surcharge, court-circuit ouverture de la détection tension): courant de plafond d'excitation pendant 10 secondes puis retour à environ 1A.

Il faut arrêter l'alternateur (ou couper l'alimentation) pour réarmer.

- protection en entrée par fusibles F1,F2.
- détection de tension : 5 VA isolée par transformateur
bornes 0-110 V = 95 à 140 V
bornes 0-220 V = 170 à 260 V
bornes 0-380 V = 340 à 520 V
réglages par potentiomètre P2
- autres tensions par transformateur d'adaptation
- détection de courant : (marche en parallèle) : T.I. 2,5 VA cl1, secondaire 1A (Option)
- réglage du statisme par potentiomètre P1
- protection en sous-vitesse (U/f) et LAM : seuil d'action réglable par potentiomètre P4
- réglage du courant d'excitation maximum par P5 : 4,5 à 8A.
- sélection 50/60 Hz par strap ST3.

5.7.3 - LAM

- LAM : action éliminée en coupant le strap ST5

5.7.2 - Regulators data

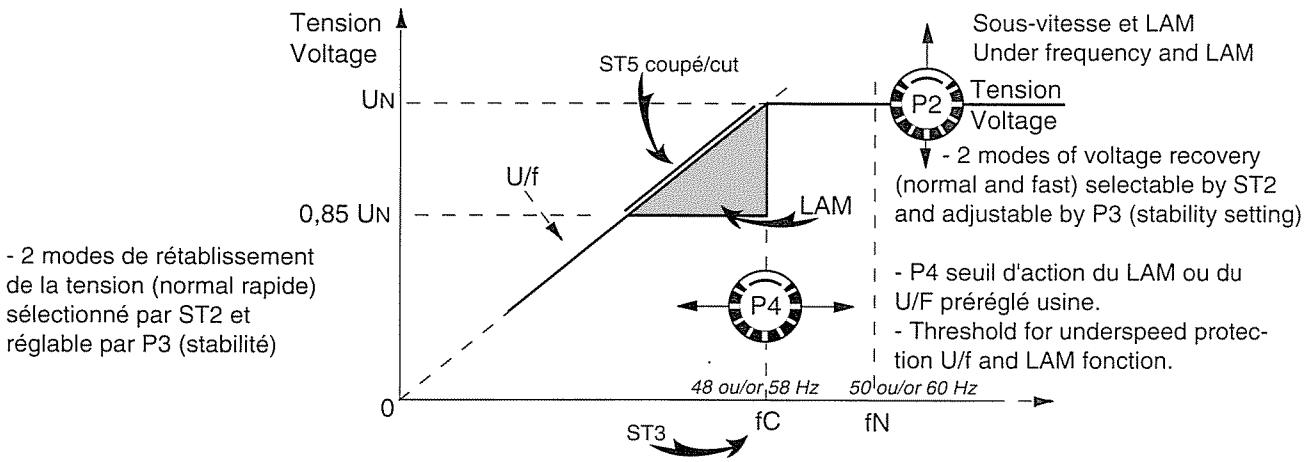
- normal power supply : 2 auxiliary windings (X1X2,Z1Z2)
- shunt supply : 100 to 150V - 50/60Hz
- rated overload current : 8A, 10s.
- electronic inbuilt protection (overload short circuit, loss of sensing): the excitation current rises to ceiling level during 10 seconds, then drops to about 1A.

The alternator must be stopped (either cut off the supply) to reset this protection.

- protection of power inputs by fuses F1,F2 .
- voltage sensing : 5 VA insulated through transformer
terminals 0-110 V = 95 to 140 V
terminals 0-220 V = 170 to 260 V
terminals 0-380 V = 340 to 520 V
- voltage adjustment by pot P2
- other voltages by using an adapting transformer
- current sensing (parallel operation) C.T. 2,5 VA class 1 secondary current 1A (optional).
- adjustment of quadrature droop with pot P1
- Underspeed protection (U/f) and LAM : threshold frequency adjustable by P4.
- adjustment of excitation ceiling current by P5: 4,5 to 8A
- 50/60 Hz selection by jumper ST3.

5.7.3 - Load acceptance module

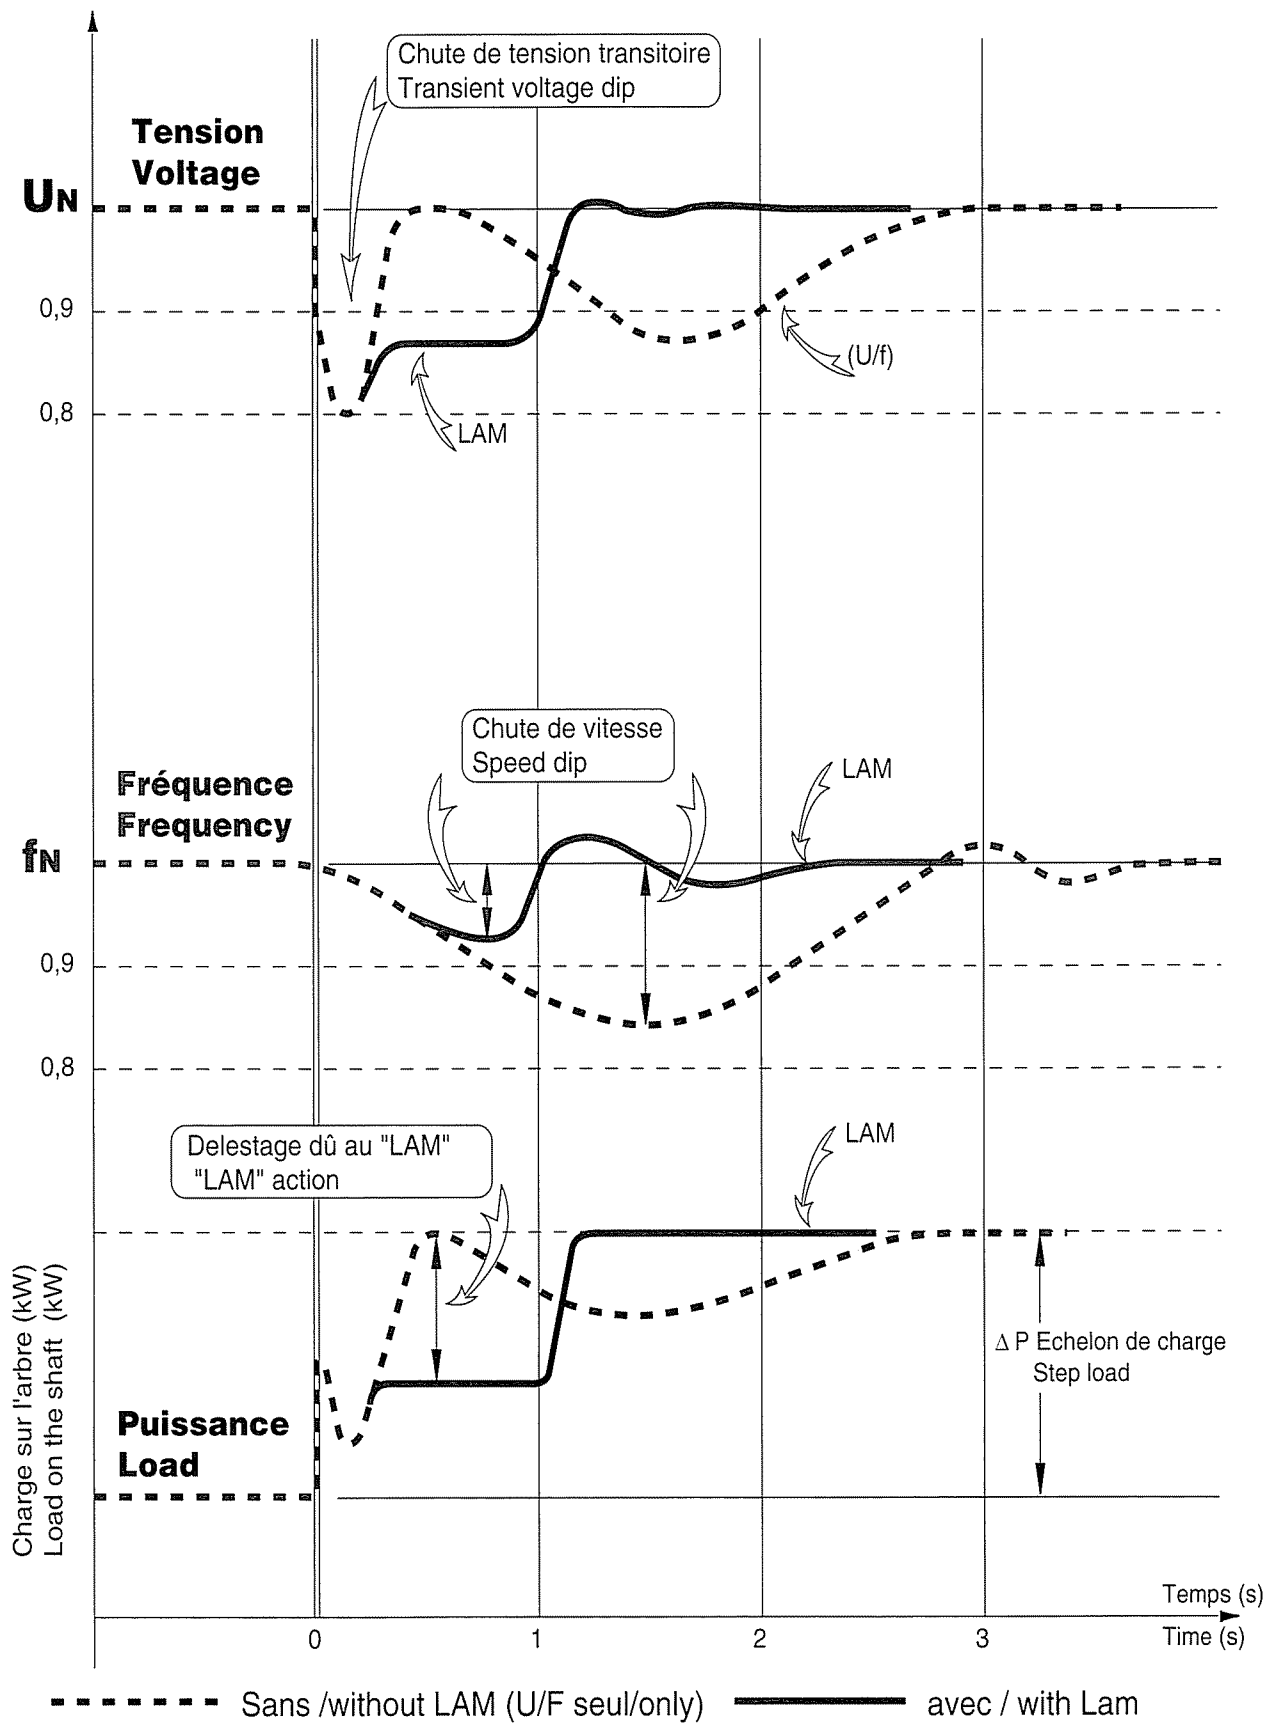
- action of LAM is suppressed by cutting ST5



- Rôle du "LAM" (Atténuateur d'à coups de charge).
A l'application d'une charge, la vitesse de rotation du groupe électrogène diminue. Quand celle-ci passe en dessous du seuil de fréquence préréglé, le "LAM" fait chuter la tension d'environ 15% et de ce fait l'échelon de charge active appliqué est réduit d'environ 25%, tant que la vitesse n'est pas remontée à sa valeur nominale.
Le "LAM" permet donc, soit de réduire la variation de vitesse (fréquence) et sa durée pour une charge appliquée donnée, soit d'augmenter la charge appliquée possible pour une même variation de vitesse (moteurs à turbo compresseurs).
Pour éviter les oscillations de tension, le seuil de déclenchement de la fonction "LAM" doit être réglé environ 2 Hz en dessous de la fréquence la plus basse en régime établi.

- LAM (Load Acceptance Module) function.
When applying a step load, the rotationnal speed (frequency) of the gen-set drops. Below the prest value of frequency the "LAM" drops the voltage of about 15% and by this way reduces the effective step of about 25%,as long as the speed has not recovered the rated value.
The "LAM" so enables, either to reduce the speed drop, and the duration of it for the same step load, or to increase the applicable step load for the same speed variation (turbo charged engines).
To prevent voltage oscillations, the frequency threshold must be adjusted about 2 Hz below the lowest frequency in normal steady state operation.

EFFETS TYPIQUES DU "LAM" AVEC UN MOTEUR DIESEL TURBO
"LAM" TYPICAL EFFECT WITH TURBO CHARGED ENGINES



5.7.4 - Options

- T.I. pour marche en parallèle
- potentiomètre de réglage de tension extérieur : 470 Ω (*) 1 W mini : plage de réglage ± 5% (centrage de la plage par le potentiomètre tension intérieur). Enlever ST4 pour raccorder le potentiomètre.
- détection de tension triphasé: module extérieur R 730 : 200 à 500 V. Couper ST1 pour raccorder le module; réglage de la tension par le potentiomètre du module
- régulation du cos φ (2eme fonction) et égalisation des tensions avant couplage en parallèle réseau (3eme fonction).

T.I. de ...../1A . 5 VA CL 1
Module R 724 : 2 fonctions - (monté à l'extérieur).
Module R 725 : 3 fonctions - (monté à l'extérieur).

- antiparasitage (cl K . VDE 0875) - module R 790

(*) N.B. : Un potentiomètre de 1 k Ω peut aussi être utilisé pour élargir la plage de variation.

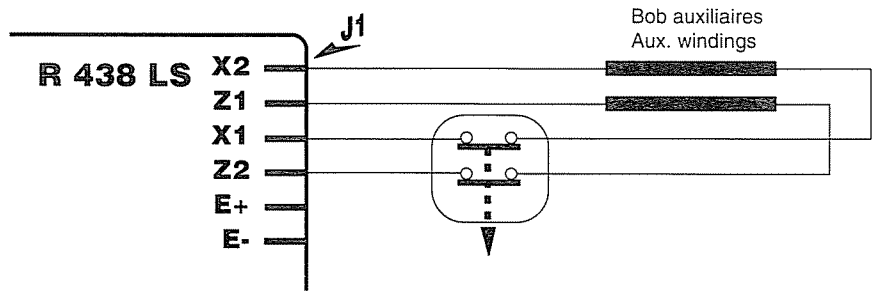
- Le module R 730 n'est pas compatible avec la marche en parallèle.

5.7.5 - Utilisations particulières

A) - Désexcitation

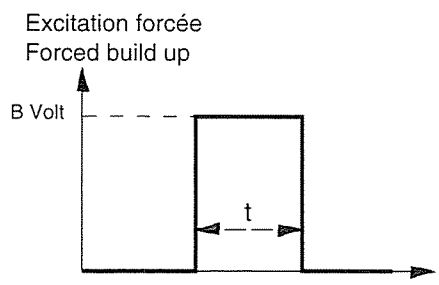
La coupure de l'excitation s'obtient par la coupure de l'alimentation du régulateur (1 fil sur chaque bobinage auxiliaire) calibre des contacts 10A - 250V alt.

Branchement identique pour réarmer la protection interne du régulateur.



Same connection to reset internal protection of AVR.

B) - Excitation forcée



5.7.4 - Optional items

- C.T. for parallel operation with other generators
- remote voltage adjusting potentiometer 470Ω .1.Wmini (*) giving an adjustment range of ± 5% (centering of the range by using internal P2 potentiometer). Remove ST4 to connect the potentiometer.
- three phase sensing : additional modul R 730 : 200 to 500 V. Cut ST1 to connect the module. Voltage is adjusted by using the voltage adjustment potentiometer on the module.
- power factor regulator (2 nd function) and voltage equalisation before paralleling with the mains (3 rd function)

C.T. ...../1A . 5 VA CL 1
Module R 724 : 2 functions - (external).
Module R 725 : 3 functions - (external).

- EMI suppression (acc VDE 0875, class k) module R790

(*) Note : For a wider voltage range - 1 kΩ /3W may be used.

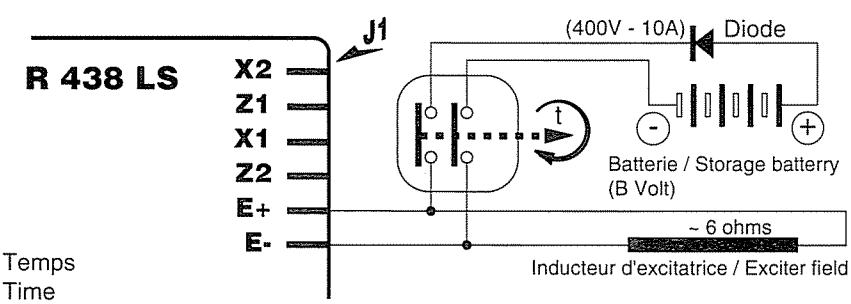
- R 730 module is not compatible with paralleling.

5.7.5 - Special applications

A) - Field de-energizing

Cutting excitation current is fulfilled by switching off the supply to AVR (1 lead on each auxiliary winding)
Contacts caliber : 10A . 250V AC

B) - Forced build-up



Applications	B VOLT	Temps / Time t	Application
Amorçage de sécurité Couplage en parallèle désexcité	6 (1 A)	1 - 2 s	Safety flashing Paralleling when de-excited
Couplage en parallèle à l'arrêt	12 (2 A)	5 - 10 s	Paralleling when at standstill
Démarrage par la fréquence Amorçage en surcharge	24 (4 A)	5 - 10 s	Frequency starting Build-up in over load

5.7.6 - Vérification préalable :
Contrôler les fusibles F1, F2.

5.7.6 - Preliminary check
Check fuses F1, F2

Katolight Service - Master Repair Manual - Page 254

Alternator
LSA 41.1, 41.2, 42.1, 44.1 - 4P

5.7.8 - Vérification statique du régulateur

*** Un fonctionnement correct du régulateur en essais statique ne signifie pas une marche correcte en conditions réelles.**
*** Si le test statique est négatif, on peut en conclure avec certitude que le régulateur est défectueux.**

- Brancher une ampoule test selon le schéma.
- La tension d'alimentation doit être comprise entre 100 et 130 V, la tension de l'ampoule est de 110 Volts. La puissance de l'ampoule sera inférieure à 100 Watts.

b) - Régler la vis de réglage tension du régulateur P2 à fond à gauche.

c) - Mettre le régulateur sous tension: la lampe doit s'allumer et s'éteindre momentanément.

d) - Tourner lentement la vis de réglage tension à droite

- à fond à droite, la lampe est allumée complètement.
- au point de régulation, une légère rotation de la vis de réglage tension dans un sens ou dans l'autre doit allumer ou éteindre la lampe. Si l'ampoule reste toujours allumée ou éteinte le régulateur est défectueux.

5.7.8 - Static test AVR

*** A proper operation of A.V.R. through static tests does not mean necessarily it can operate properly in réal situation.**
*** Reversely, if the A.V.R. does not react properly during static tests, it is obviously out of duty.**

- Connect the test setup as shown here after.
- The supply voltage must be in the range 100 - 130 V and the lamp voltage either 110 V.

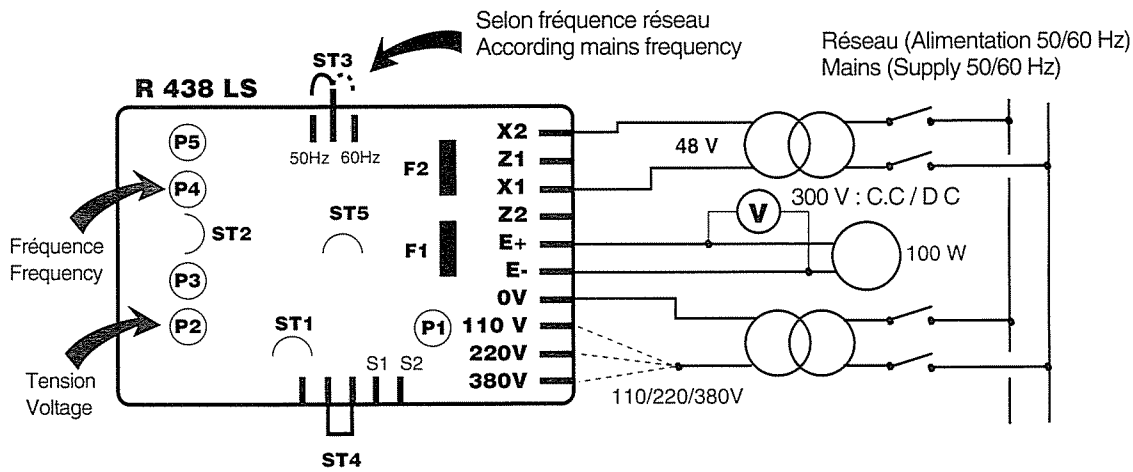
Lamp power : less than 100 Watt

b) - Adjust regulator voltage; adjust screw P2 to maximum CCW

c) - Apply power to the AVR : lamp should flash momentarily

d) - Slowly rotate the AVR voltage screw clockwise:

- the lamp reaches full brillance before to be fully clockwise
- at the regulating point a small change in the screw position turns on or off. If the lamp remains dark or light the AVR is not operating.



Faire un premier essai en alimentant le régulateur par les bornes X1, X2, puis un second par les bornes Z1,Z2.

Make an intial test by supplying AVR through terminals X1,X2, then a second test by supplying it through terminals Z1,Z2.

5.7.9 - Vérification statique du LAM (sous-vitesse)

- potentiomètre de tension P2 en position juste allumé, tourner le potentiomètre P4 lentement vers la gauche. L'éclat de la lampe doit baisser brusquement: la tension chute à environ 85 % de la tension d'alimentation. Revenir à la position de départ de P4. La lampe doit briller comme précédemment.

5.7.9 - Static test LAM (underspeed protection)

- the voltage adjustment P2 should be preset in position where the lamp just begins to glow. Turn P4 slowly CCW the brightness should decrease suddenly : voltage at AVR's output E+, E- falls about 15%. Then reset P4 to initial position : the lamp should glow as before.

5.8 - Réglage du régulateur R 438 LS

5.8.1 - Réglage tension , LAM (ou U/F) stabilité

Action	Réglage usine(R.U.)	Pot.	Action	Factory adjustment (A.F)
Tension minimum à fond à gauche	400V - 50 Hz (Entrées 0 - 380 V)		**Voltage** minimum fully CCW	400V - 50 Hz (0 - 380 V)
Stabilité	Non réglé (position milieu)		**Stability**	Not adjusted (middle)
Seuil/LAM ou U/F Seuil de la protection de sous-vitesse et déclenchement du "LAM" Maxi de fréquence à fond à gauche	ST3 = Position 50 Hz (R.U.) = 48 Hz ST3 = Position 60 Hz (R.U.) = 58 Hz		**THreshold/LAM or U/F** Threshold for under-speed protection U/f and LAM function	ST3 on 50 Hz (A.F..) = 48 Hz ST3 on 60 Hz (A.F.) = 58 Hz
Statisme de tension (Marche en // avec T.I.) - Statisme 0 à fond à gauche.	Non réglé (à fond à gauche.)		**Quadrature voltage droop** (Parallel operation with C.T.) - No droop fully CCW	Not adjusted (fully CCW)
Plafond d'excitation Limitation du courant d'excitation et du courant de court-circuit, minimum à fond à gauche	10 A ou maximum		**Ceiling excitation current** Excitation current and short circuit current limitation, minimum fully CCW	10 A or maximum

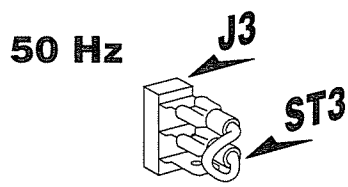
5.8.1.1 - Sélection des modes de fonctionnement
- détection de tension (transformateur)

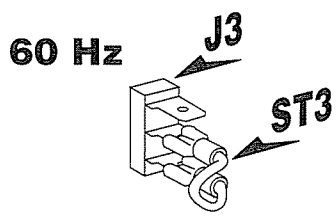
R.U. = 0 - 380 V

	Bornes / Terminals		
50 Hz et/and 60 Hz	0 - 110 V	0 - 220 V	0 - 380 V
Plages / Ranges	95 - 140 V	170 - 260 V	340 - 520 V

A.F. = 0 - 380 V

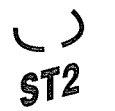
- fréquence (protection + LAM) , selecteur ST3
R.U. = 50 Hz





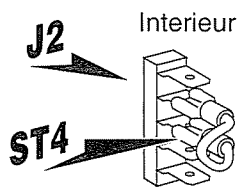
- frequency (protection + LAM), selector jumper ST3
A.F. = 50 Hz

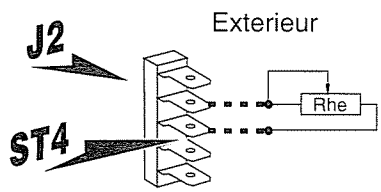
- temps de réponse : strap ST2
R.U. = normal



- voltage recovery speed : link ST2
A.F. = standard

- réglage de tension : ST4
R.U. = interieur





- voltage setting : ST4
A.F. = Internal

Katolight Service - Master Repair Manual - Page 256

Alternator
LSA 41.1, 41.2, 42.1, 44.1 - 4P

5.8.1.2 - Procédure de réglage
a) Position initiale des potentiomètres
- P2 TENSION : minimum à fond à gauche.
- P3 STABILITE : milieu.
- P1 STATISME : 0 à fond à gauche.
- P5 PLAFOND D'EXCITATION : ne pas toucher si non nécessaire (voir 5.8.2.), maximum à fond à droite.
- Potentiomètre extérieur Rhe = 470 Ω (strap ST4 enlevé) : milieu.

b) Installer un volmètre analogique (à aiguille) cal. 50V C.C. aux bornes E+, E- et un volmètre C.A. cal 300 - 500 ou 1000V aux bornes de sortie de l'alternateur.

c) S'assurer que le strap 50/60 HZ est positionné sur la fréquence souhaitée.

d) Potentiomètre tension (P2) au minimum, fond à gauche (sens anti-horaire).

e) Tourner le potentiomètre V/Hz (P4), fond à droite (sens horaire).

f) Potentiomètre stabilité (P3) aux environs d'1/3 de la butée anti-horaire.

g) Démarrer et régler la vitesse du moteur à la fréquence de 48 Hz pour 50 Hz, ou 58 pour 60 Hz.

h) Régler la tension de sortie par (P2) à la valeur désirée.
- tension nominale UN pour fonctionnement en solo (par ex. 400 V)
- ou UN + 2 à 4% pour marche parallèle avec T.I. (par ex. 410V -)

Si la tension oscille, régler par (P3) (essayer dans les 2 sens) en observant la tension entre E+ et E- (env 10V C.C.). Le meilleur temps de réponse s'obtient à la limite de l'instabilité. S'il n'y a aucune position stable, essayer en coupant ou en remettant le strap ST2 (normal /rapide).

i) Tourner lentement le potentiomètre (P4) dans le sens anti-horaire jusqu'à une chute de tension importante (environ 15 %).

j) Faire varier la fréquence (vitesse) de part et d'autre de 48 ou 58 Hz selon la fréquence d'utilisation, et vérifer le changement de tension vu précédemment (~ 15%).

k) Réajuster la vitesse du groupe à sa valeur nominale à vide.

RÉGLAGES EN MARCHE PARALLÉLE

NB : Avant toute intervention sur l'alternateur s'assurer que les statismes de vitesse des moteurs sont identiques.

l) Préréglage pour marche en parallèle (avec T.I. raccordé à S1, S2 du connecteur J2)
- Potentiomètre P1 (Statisme) en position milieu.

Appliquer la charge nominale (cos φ = 0,8 inductif).
La tension doit chuter de 2 à 3 %. Si elle monte, permuter les 2 fils arrivant du secondaire du T.I.

m) Les tensions à vide doivent être identiques sur tous les alternateurs destinés à marcher en parallèle entre eux.
- Coupler les machines en parallèle.
- En réglant la **vitesse** essayer d'obtenir **0 Kw**

5.8.1.2 - Adjustment procedure
a) Initial setting of potentiometers
- P2 VOLTAGE : lowest fully CCW.
- P3 STABILITY : middle position.
- P1 QUADRATURE VOLTAGE DROP : fully CCW
- P5 EXCITATION CURRENT LIMIT : to be adjusted only if necessary (see 5.8.2.) maximum fully CW.
- Remote voltage trimmer Rhe - 470 Ω (jumper ST4 removed) : middle position.

b) Connect one analoge (needle) voltmeter cal. 50V D.C. across E+, E- terminals and another (300V - 500V or 1000V A.C. across the alternator output terminals.

c) Make sure that the 50/60 Hz link is correctly connected.

d) (P2) potentiometer must be set maximum anti-clokwise.

e) (P4) (V/Hz) must be set maximum clokwise.

f) (P3) (Stability) has to be adjusted maximum clokwise -1/3.

g) Start and adjust the engine speed corresponding to 48 Hz for 50 Hz (nominal) or 58 for 60 Hz.

h) Adjust output voltage with (P2) to the required value
- rated voltage UN if generator operates alone (for example 400V)
- or UN + 2 to 4% for parallel operation with C.T. (i.e. 410V - see below)

If voltage is unstable, adjust (P3) (try in both directions), noting voltage across E+, E- (approx.10V D.C.). The fastest recovery time may be achieved when (P3) is set close to the limit of unstability. If there is none stable position try another adjustment after having cut or reconnected link ST2 (normal / fast).

i) Turn (P4) anticlockwise until the voltage drops (about 15 %)

j) Modify the speed value around 48 or 58 Hz in order to check the LAM voltage drop (~ 15%).

k) Readjust the speed of gen-set to its normal no-load level.

ADJUSTMENTS IN PARALLEL OPERATION

Note : Preliminary to any adjustment on the alternator, make sure the speed statism of the engines are similar.

l) Presetting for parallel operation (with C.T. connected to terminals S1,S2 of terminal strip J2)
- Potentiometer P1 (Voltage droop) in middle position.

Switch on the rated load (P.F. 0,8 inductive). The output voltage should drop 2% to 3%. If it raise, change over the 2 leads coming from C.T. secondary.

m) No load voltages must be identical on all gen-sets required to work together in parallel.
- Synchronise and parallel the gen-sets together.
- By adjusting **speed** , try to reduce the power exchange. to **0 KW**
- By adjusting voltage pot (P2 or Rhe) on one of the machines try to cancell (or minimize) the circulating **current**.

d'échange de puissance.
- En agissant sur le réglage de tension P2 ou Rhe d'une des machines, essayer d'annuler (ou minimiser) **le courant** de circulation entre les machines
- **Ne plus toucher aux réglages de tension.**

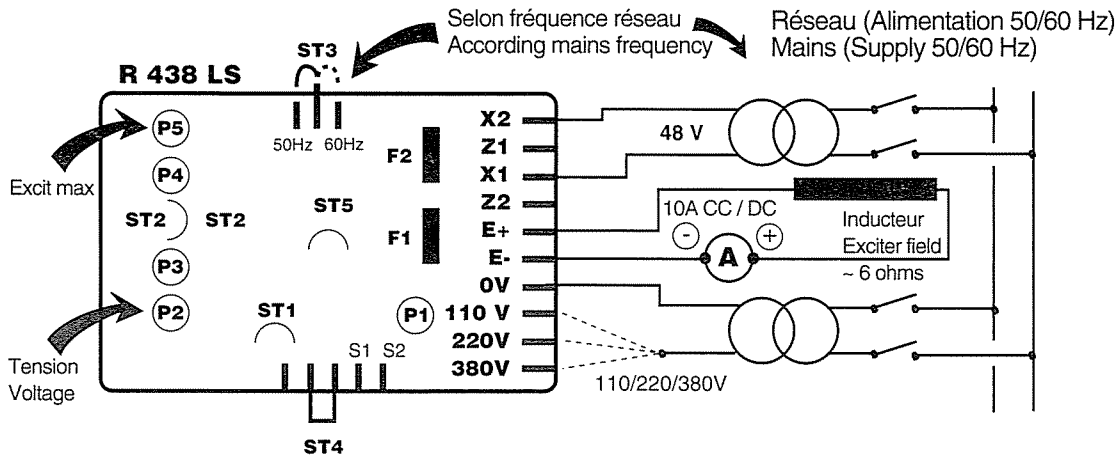
n) Appliquer la charge disponible (le réglage ne peut être correct que si on dispose de charge **réactive**)
- En agissant sur la **vitesse** égaliser les **KW** (ou répartir proportionnellement aux puissances nominales des groupes)
- En agissant sur le potentiomètre statisme **P1**, égaliser ou répartir les **courants**.

5.8.2 - Réglage excitation maxi (plafond d'excitation)
- réglage statique de la limitation de courant, potentiomètre P5 (réglage usine : 7,5 A, calibre des fusibles : 6,3A - 10 secondes)

- Do not alter the voltage adjustments.

n) Switch on the available load (correct adjustment cannot be made if there is no **reactive** load).
- By adjusting **speed** , balance the KW (proportionnally to the rated powers of gen-sets).
- By adjusting Voltage droop pot. **P1** , balance the output currents.

5.8.2 - Adjustment of maximum excitation current (Excitation ceiling)
- static adjustment of excitation current limitation, potentiomètre P5 (factory adjustment : 7,5 A, fuse caliber : 6,3 A - 10 seconds).



Le réglage usine correspond à celui du courant d'excitation nécessaire pour obtenir un courant de court-circuit triphasé d'environ 3 IN à 50 Hz pour la puissance industrielle, sauf spécification autre.(*)
Pour reduire cette valeur ou pour adapter le Icc à la puissance réelle maxi d'utilisation (machine déclassée) on peut procéder à un réglage statique à l'arrêt, non dangereux pour l'alternateur et l'installation. Débrancher les fils d'alimentation X1,X2 et Z1,Z2 la référence tension (0-110V-220V-380V) de l'alternateur.
Brancher l'alimentation réseau (200-240V) comme indiqué (X1,X2 : 0-110V). Installer un ampèremètre 10A C.C. en série avec l'inducteur d'excitatrice. Tourner P5 à fond à gauche, enclencher l'alimentation. Si le régulateur ne débite rien, tourner le potentiomètre P2 (tension) vers la droite jusqu'à ce que l'ampèremètre indique un courant stabilisé.Couper et remettre l'alimentation, tourner P5 vers la droite jusqu'à obtenir le courant maxi désiré (se limiter à 8 A).
Vérification de la protection interne:
Ouvrir l'interrupteur (D): le courant d'excitation doit croître jusqu'à son plafond pré-réglé, s'y maintenir pendant un temps ≥ 10 seconds et retomber à une valeur < 1A.
Pour réarmer il faut couper l'alimentation par l'interrupteur (A).
Nota : Après réglage du plafond d'excitation selon cette procédure, reprendre le réglage de tension selon § 5.8.1.2.
(*): Avoir un courant de court-circuit égal à 3 IN est une obligation légale dans plusieurs pays pour permettre une protection selective.

The factory adjustment corresponds to the excitation current for a sustained 3 phase short circuit, of about 3 times the rated current ,unless otherwise specified.(*)
It is possible to reduce the maximum excitation level by a static method which is safer for the alternateur and the network.
Disconnect the supply leads (X1,X2,Z1,Z2) and sensing leads (0-110-220-380) from A.V.R.. Connect the supply as shown (X1,X2,0,110V). Connect an ammeter (10A , dc) in series with the exciter field. Turn P5 fully CCW. Switch on the supply. If there is no output current from AVR, turn P2 (voltage) clockwise until ammeter indicates a stabilized current.
Switch the supply off, then on again. Turn P5 clockwise until the required current is obtained in the exciter field. (limit to 8A)
Checking internal protection :
Switch off (D) : the excitation current must rise to the pre-set high level, and remain at this level for a period of more than 10 seconds, than fall to less than 1A.
To reset, switch off the supply by opening switch (A).

Note : After having adjusted the excitation current limitation as indicated above, proceed to the voltage/frequency adjustment according to § 5.8.1.2.

(*) : In many countries the short-circuit current equal to 3 IN is obligatory in order to allow selective tripping of circuit breakers.

Katolight Service - Master Repair Manual - Page 258

6 - DEMONTAGE - REMONTAGE

6.1 - Accès aux connexions et au système de régulation

6.1.1 - LSA 41.1,41.2, 42.1.

L'accès aux bornes se fait directement après avoir enlevé la partie supérieure du capotage (48) .
Afin de faciliter l'accès aux potentiomètre de réglage du régulateur ,il est conseillé de démonter la plaque latérale le supportant et de la refixer en position inversée (fig 1).

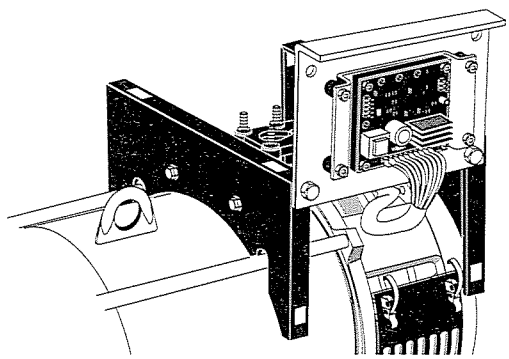


Fig 1

6.1.2 - LSA 44.1.

L'accès aux bornes se fait directement après avoir enlevé la partie supérieure du capotage (48) .
L'accès aux régulateur se fait directement après avoir enlevé la porte du capotage (466)(fig 2) .

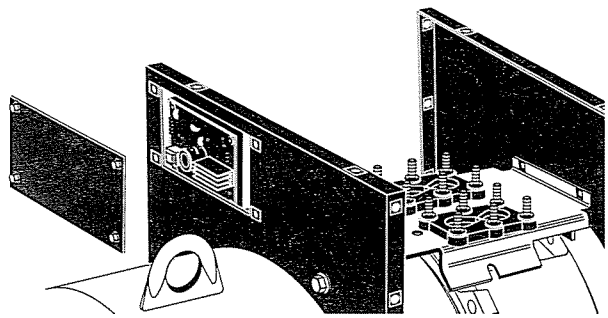

Fig 2

6.2 - Accès aux diodes

- Retirer la grille d'entrée d'air (51)
- Débrancher les diodes
- Vérifier les 6 diodes à l'aide d'un ohmmètre ou d'une lampe (cf § 5 - 4).

6.3 - Remplacement des diodes (LSA 41.1, 41.2)

6.3.1- Démontage

- Déposer le capot supérieur (48)
- Déconnecter le régulateur et les planchettes à bornes.
- Déposer les 2 vis HM6 et les vis CHc M6 du support de planchettes (120) et extraire l'ensemble boite à bornes.
- Démonter le flasque arrière (36)
- Retirer la varistance (347)
- Démonter les 4 vis "H" de fixation des ponts de diodes sur le support (107)

6.3.2- Remontage

- Remonter les ponts en respectant les polarités (cf § 5 - 4).
- Remonter la varistance (347)
- Remonter le flasque arrière, passer le faisceau de câbles entre les barrettes supérieures du flasque.
- Remonter l'ensemble boite à bornes.
- Reconnecter la machine selon schéma de connexions.
- Reposer le capot supérieur (48).

6.4 - Remplacement des diodes (LSA 42.1/LSA 44.1)

6.4.1- Démontage

- Retirer la grille d'entrée d'air (51).
- Débrancher les diodes.
- Retirer la varistance (347)
- Déposer les croissants support de diodes.

6 - DISMANTLING - REASSEMBLY

6.1 - Access to connections and regulation system

6.1.1 - LSA 41.1,41.2, 42.1.

Access to the terminals by removing the terminal box lid (48).
In order to facilitate the A.V.R. adjustments it is adviced to remove the side panel holding the A.V.R. and to return it (refer to fig 1).

6.1.2 - LSA 44.1.

Access to the terminals by removing the terminal box lid (48).

Access to the A.V.R. by removing the terminal box panel (466).
(Refer to fig 2).

6.2 - Diodes access

- Remove the air inlet screen (51)
- Disconnect the diodes and check the diodes either by ohmeter or battery lamp (ref § 5 - 4).

6.3 - Replacement of diodes (LSA 41.1, 41.2)

6.3.1 - Dismantling

- Remove the terminal box cover (48).
- Disconnect A.V.R and terminals plate.
- Remove two screws HM6 and two screws CHc M6 of terminal plate support (120) and remove the complete terminal box .
- Remove N.D.E. bracket (36).
- Remove the surge suppressor (347) .
- Remove the diode crescent assembly.

6.3.2 - Reassembling

- Replace diode crescent to respect polarity (cf § 5 - 4).
- Reassemble the surge suppressor (347).
- Reassemble N.D.E bracket (36).
- Fix the terminal box assembly , connect the terminals in according to connection diagram.
- Fix the terminal box cover (48).

6.4 - Replacement of diodes (LSA 42.1/LSA 44.1)

6.4.1 - Dismantling

- Remove the air inlet screen (51)
- Disconnect the diodes.
- Remove the surge suppressor (347) .
- Remove the diode crescent assembly.

Alternator
LSA 41.1, 41.2, 42.1, 44.1 - 4P

6.4.2- Remontage
- Changer les diodes défectueuses en respectant les polarités (cf § 5 - 4).
- Remonter les croissants support de diodes.
- Remonter la varistance (347).
- Rebrancher les diodes.
- Reposer la grille d'entrée d'air (51).

6.5 - Remplacement du roulement arrière

6.5.1- Démontage
- Démonter le flasque arrière (36) cf § 6.3.1.
- Enlever le roulement (70) à l'aide d'un extracteur à vis centrale

6.5.2- Remontage
- Monter un roulement neuf après avoir chauffé sa bague intérieure par induction ou en étuve à 80 °C (ne pas utiliser de bain d'huile).
- Placer la rondelle de précharge (79) dans le flasque et installer un joint torique neuf (349).
- Remonter le flasque arrière (36) cf § 6.3.2.

6.6 - Remplacement des roulements sur machine bipalier

6.6.1 - Démontage
- Désaccoupler l'alternateur du moteur d'entraînement.
- Déposer le capot supérieur (48).
- Déposer les 4 écrous (38).
- Déposer les 2 vis (62) du flasque AV (30) .
- Déposer le flasque AV(30)
- Extraire l'ensemble rotor (4) en faisant attention à ne pas endommager les bobinages.
- Retirer le circlips (284)
- Enlever les 2 roulements (60) et (70) à l'aide d'un extracteur à vis centrale.

6.6.2 - Remontage
- Monter le chapeau intérieur (68) sur le rotor.
- Monter des roulements neufs après les avoir chauffés par induction ou en étuve à 80 °C (ne pas utiliser de bain d'huile).
- Remonter le circlips (284).
- Vérifier la présence de la rondelle de précharge (79) et du joint torique (349) dans le flasque AR (36).
- Glisser le rotor (4) dans le stator.
- Visser sur le chapeau (68) une tige filetée M6 x 200 pour effectuer son montage (fig 3).
- Remonter le flasque avant (30), bloquer les 4 écrous (38) au couple de 3,8 m.da/N.
- Fixer le chapeau intérieur (68) par la vis inférieur (62) remplacer la tige filetée par la seconde vis (62).
- Reposer le capot supérieur (48).
- Vérifier le montage correct de l'ensemble de la machine et le serrage de toutes les vis.

NOTA: Lors d'un démontage total (rebobinage) ne pas oublier de réequilibrer le rotor

6.4.2 - Reassembling
- Replace diode damaged to respect polarity (ref § 5 - 4).
- Reassemble M.O. varistor (347).
- Connect the diodes
- Replace the air inlet screen (51)

6.5 - N.D.E. bearing replacing

6.5.1 - Dismantling
- Remove N.D.E. bracket (36) ref § 6.3.1.
- Extract bearing (70) with a bearing puller

6.5.2 - Reassembling
- Position the new ball bearing after heating its internal ring, by induction system at 80°C or in an oven at 80°C (do not use hot oil bathing).
- Install in N.D.E bracket the spring washer (79) and a new rubber "O" ring (349)
- Reassemble N.D.E bracket (36) ref § 6.3.2.

6.6 - Replacing of two bearing (two bearing units only)

6.6.1 - Dismantling
- Take off the alternator from the engine.
- Remove the terminal box cover (48).
- Remove the 4 nuts (38) fixing the endshield.
- Remove 2 screws (62).
- Remove D.E bracket (30).
- Remove rotor (4) taking care of not damaging windings.
- Remove circlip (284)
- Remove bearings (60) and (70) with a bearing puller.

6.6.2 - Reassembling
- Position the inner bearing cap (68) on the rotor
- Position the new ball bearing after heating it, by induction system at 80° C or in an oven at 80°C (do not use hot oil bathing).
- Position circlip (284)
- Place rubber "O" ring (349) the spring washer (79) into the recess in the non drive end bearing housing (36).
- Replace rotor (4) into the stator.
- Insure the alinement of the bearing cap (68) with the D.E. bracket (refer to fig 3)
- Replace the drive end bracket (30) on the stator (1) fasten by nuts (38) torqued at 3,8 m.da/N on studs (37).
- Fix the inner bearing cap (68) with lower bolt (62) and replace the rod by upper bolt (62).
- Fix the terminal box cover (48).
- Check that all nuts and bolts are correctly tightened

Note : If the rotor has been rewound, it must be rebalanced.

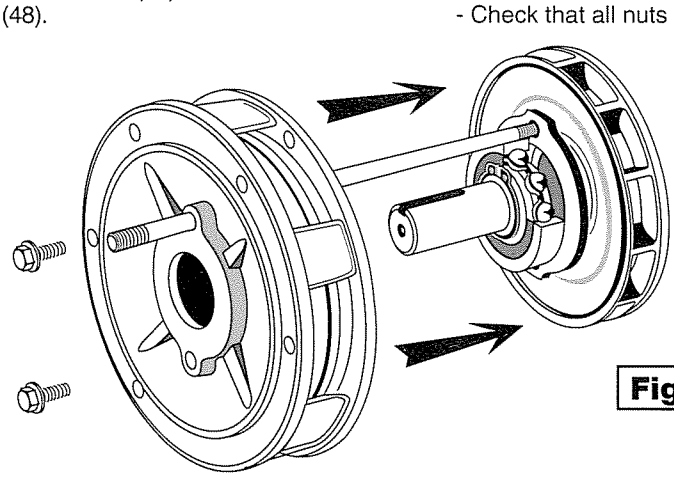

Fig 3

Five Year PTO Driven Alternator Standby Limited Warranty

Your Katolight Product has been manufactured and inspected with care by experienced craftspeople. If you are the original consumer, Katolight Corporation warrants, for the period indicated below, each product to be free from defects in materials and workmanship. Repair, replacement or appropriate adjustment at Katolight Corporation's option will be furnished if the product, upon Katolight Corporation's inspection, is properly installed, maintained and operated in accordance with Katolight Corporation instruction manuals. This warranty does not apply to malfunctions caused by damage, unreasonable use, misuse, repair or service by unauthorized persons, or normal wear and tear.

KATOLIGHT PRODUCT PERIOD OF WARRANTY: PTO Driven Alternator complete with Gear Box: Five (5) years parts, site and / or shop labor for the first two (2) years from date of purchase. Accessories: One (1) year parts and site or shop labor form date of purchase.

For a description of accessories and exclusions from this limited warranty, review the listings on the reverse side of this document.

TO OBTAIN WARRANTY SERVICE: Contact your nearest Katolight Service Representative by calling or writing Katolight Corporation.
Attention: Service Department.
Phone: (507) 625-7973 / Fax: (507) 625-2247 / www.katolight.com

Katolight shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall Katolight be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING BUT NOT LIMITED TO A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

State laws regarding rights of consumers may vary from state to state.

1. The following items are among those that are not considered nor will they be covered under the existing warranty program.
   a. Normal maintenance costs.
   b. Non-Katolight replacement part(s) will void the entire limited warranty.
   c. Products that are modified in any form without the written consent of Katolight will void the entire limited warranty.
   d. Shipping damage of any type. All equipment is shipped F.O.B. factory and is consigned to the carrier once loaded for shipment. It is the responsibility of the receiver to sign and note any damage to the equipment and a freight damage claim filed by the receiver.
   e. Any installation errors or damage of the equipment when shipped as ordered.
   f. Any overtime labor to make repairs under warranty.
   g. Any special access fees required to gain access to Katolight equipment not limited to but including any training or safety policy requirements to gain access.
   h. Additional costs associated with inaccessible installations, including removal and reinstallation of the generator.
   i. Rental equipment used during warranty work such as generators, rigging equipment such as a crane or boom truck, tractors, load banks and special testing above factory requirements, etc.
   j. Misuse or abuse including installation and thereafter.
   k. Normal wear and tear, maintenance and consumable items that are not required as part of a warranty repair. Consumable items include but are not limited to gear lube and fuses.
   l. Acts of nature such as lightning, wind, flood, or earthquake.
   m. Any damage due to situations beyond the control of the manufacturing of the product or workmanship of the product.
   n. Installation or operation outside the guidelines as stated in the Installation Guide and Owners Manual.
   o. Misapplication of the equipment such as usage outside the original design parameters as stated on the nameplate of the equipment.
   p. Shaft or spline damage caused by improper shaft alignment.
   q. Damage from improper storage when not in use.
   r. Any repair labor time that is determined to be excessive, e.g., two or more people performing a one-person job.
   s. Any expenses associated with investigating performance complaints in which no defect is found.
   t. Any associated costs for replacing components that are found not to be defective.

2. The aforementioned is a representation of things not covered by the standard "**LIMITED WARRANTY".** If there are questions as to warranty coverage it is advisable to contact the factory in advance of filing a claim.

3. The accessories that are limited to one (1) year parts and labor include but are not limited to:
   a. Tap changing switches
   b. Circuit Breakers
   c. Cords and receptacles.
   d. Trailer
   e. PTO Shaft
   f. Manual Transfer Switches

ALTERNATOR DATA

The alternators described in this manual are 1800 RPM revolving field brushless type with Automatic Voltage Regulation. Output voltage may be varied by turning the voltage adjust potentiometer.

Standard equipment includes: Speed Monitor Light, Automatic Voltage Regulator, Brushless Revolving Field Type Alternator, Mainline Circuit Breaker, 15 Amp 120 Volt 3 Wire Duplex Receptacle, 50 Amp 240 Volt 4 Wire Receptacle, Full Load Connector, PTO / Gearbox, Safety Shield, Lifting Eyes, Helical Gears, Mounting Base, Gear Lube, Grounding Terminal, 1800 RPM Slow Speed, Rodent Screen & Drip Proof Design.

CONNECTOR CHECKLIST 24

TERMINOLOGY 25

INTRODUCTION

Before any Katolight PTO Driven Alternator is shipped from the factory the alternator is inspected and tested for performance. All units are load tested prior to shipment. Carefully unpack the unit and visually inspect it for damage. If it is damaged, check with the transportation carrier for adjustment of the damage. Before placing the unit in operation, check the gearbox gear lube level. If empty, or below the level check plug and fill with EP90 weight gear oil to check plug level.

If upon installation a new alternator does not work properly, check all electrical connections and the alternator speed before concluding the alternator is defective.

DETERMINING YOUR SPECIFIC LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor which will be operated by the unit. The following chart lists approximate running or operating watts required for various electrical appliances.

TABLE B
APPROXIMATE WATTS REQUIRED
FOR ELECTRICAL APPLIANCES

APPLIANCE	WATTS
Lamp Bulbs	See wattage on bulbs
Radio	40 - 200
Television	150 - 300
Vacuum Cleaner	200 - 750
Automatic Washer	400
Air Conditioner (3/4 Ton)	1,250
Refrigerator	325
Food Freezer	300
Furnace (Oil)	700
Deep Well Pump	2,000
Electric Range	600 - 10,000
Hot Plate (per burner)	600 - 1,200
Toaster	600 - 1,130
Water Heater	1,500 - 5,000
Glow Heater	600 - 1,200
Heating Pad	40 - 80
Sun Lamp	250 - 1,000
Flat Iron	600 - 1,200
Laundry Dryer	4,750
Electric Heat System	5,000 - 20,000

Check all appliance nameplates for exact ratings.

HOW ELECTRIC MOTORS ARE CLASSIFIED, AND WHAT THEIR RATINGS MEAN

Electric motors require more current (amperes) starting than running. Split-phase motors are difficult to start and require 5 to 10 times as much current to start as to run, dependent on the NEMA code letter rating. Capacitor motors require 2 to 4 times as much current to start as to run. Repulsion Start Induction Motors require 1½ to 2½ times as much current to start as to run.

The chart below shows the approximate current required to run and start 120 volt, 60 cycle, NEMA Code F induction motors under average load conditions.

Horse Power	Running Amperes	Starting Amperes
1/6	4.4	7 to 15
¼	5.8	10 to 15
1/3	7.2	15 to 25
1/2	9.8	20 to 30
1	16.0	40 to 50

The NEMA code letter assigned by the motor manufacturer will govern the starting (locked rotor) current surge. The chart below shows the NEMA code letters and their corresponding range of multipliers for the starting current requirement in amperes.

NEMA Code letter Motor Rating	Kilovolt-Amperes per Horsepower (Locked Rotor)
A	0 - 3.14
B	3.15 - 3.54
C	3.55 - 3.99
D	4.0 - 4.49
E	4.5 - 4.99
F	5.0 - 5.59
G	5.6 - 6.29
H	6.3 - 7.09
J	7.1 - 7.99
K	8.0 - 8.99
L	9.0 - 9.99
M	10.0 - 11.19
N	11.2 - 12.49
P	12.5 - 13.99
R	14.0 - 15.99
S	16.0 - 17.99
T	18.0 - 19.99
U	20.0 - 22.39
V	22.4 - and up

Here is a formula for amps:

The starting current for 1 h.p. Code F 230 V.A.C.

1 x 5.6 = 5.6 KVA inrush

$$\text{Amp} = \frac{\text{KVA}}{\text{Volts}} = \frac{5.6 \times 10^3}{230} = 24.3 \text{ amp inrush or starting}$$

Because the heavy surge of current required for starting motors is needed only for an instant, the alternator will not be damaged if it can bring the motor up to speed in a few seconds. If difficulty is experienced in starting motors, turn off all other electrical loads and, if possible, reduce the load on the electric motor.

NOTE

IN APPLICATIONS WHERE SEVERAL MOTORS ARE TO BE STARTED, EXCESSIVE OVERLOAD MAY BE AVOIDED BY STARTING THEM ONE AT A TIME. START THE MOTOR THAT REQUIRES THE HIGHEST RUNNING AND STARTING CURRENT FIRST.

INSTALLING THE ALTERNATOR

Provide sufficient ventilation. Do not operate tractor driven alternator in a non-ventilated area. Do, however, provide protection from heavy snow or dust which may plug air cleaners and ventilation openings.

For best operation, the following factors should be taken into consideration:

1. Dirt - Dust particles and dirt can cause excessive wear, not only to bearings but to all rotating parts of the alternator.

2. Moist or wet conditions are hazardous. In addition, all electrical equipment should be protected from excessive moisture which deteriorates insulation and causes short circuits.

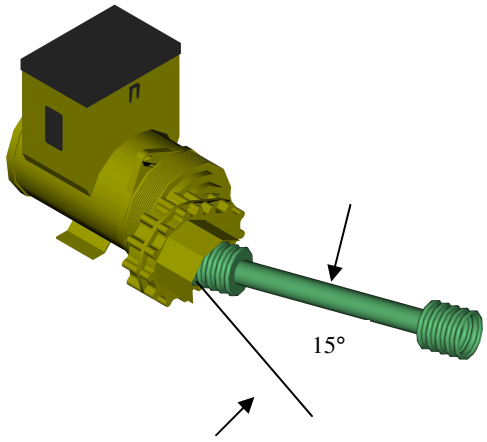
The generator must be stored properly. Protect it from moisture and dirt. If the unit is to be left in the open, it should be covered whenever it is not in use. All ventilating openings should be cleaned periodically and kept clear and open while operating.

MOUNTING THE ALTERNATOR

The alternator must be solidly bolted to a foundation, platform or bed of a trailer. The feet on the alternator must contact the foundation or trailer bed. If space is left between a mounting foot and the foundation or trailer, shim it to take up the space and then insert and tighten bolts.

ALIGNING ALTERNATOR WITH TRACTOR POWER TAKE-OFF

The double universal joint construction of the power take-off drive shaft allows for considerable angular misalignment between the gearbox and the tractor power take-off shaft. As shown in Figure 1 the angular misalignment of the universal joints, if at all possible, should not be more than 15 degrees. If the power take-off drive shaft is taken apart, make certain the drive shaft universal joint knuckles are in time with one another as shown in Figure 2. If the drive shaft universal joint knuckles are not in time, chattering will occur which will cause a flicker in the electrical output. The same flicker will also occur if the angle of the drive shaft from the alternator to the tractor power take-off is more than 15 degrees. Make certain the power take-off shaft lock pin is properly engaged and the removable power take-off shaft shields are installed before operating the unit.



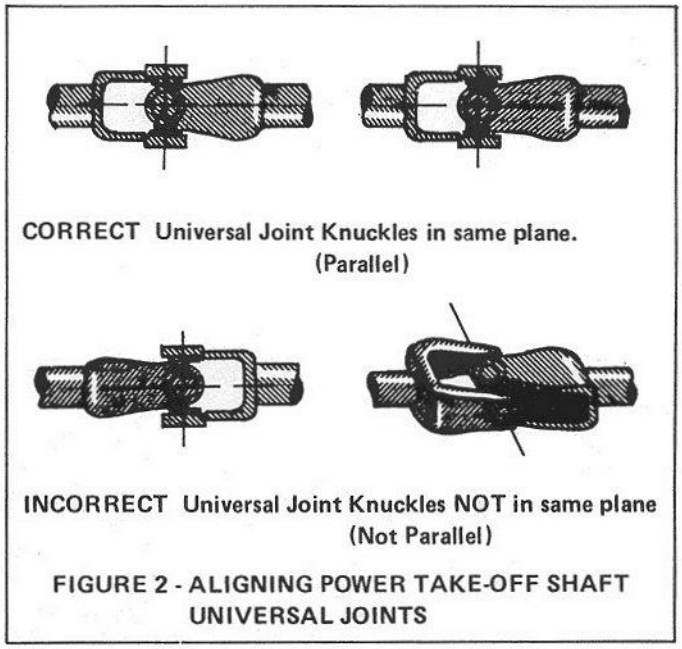


FIGURE 2 - ALIGNING POWER TAKE-OFF SHAFT UNIVERSAL JOINTS

CONNECTING ALTERNATOR TO LOAD

* Load can be taken from receptacles or by connecting the Alternator into an existing service through the full load connector plug.
* Load taken from receptacles should not exceed the respective receptacle rating and should never exceed the alternator rating. The 120 VAC duplex receptacle is rated for 15 amps and the 240 VAC receptacle is rated at 50 amps. Both receptacles and the full load plug are protected by individual overload protection circuit breakers.

* Load taken from the full load cord set should not exceed the full load rating of the alternator.
* When the Alternator is connected into an existing service normally supplied by commercial power an approved TRANSFER SWITCH MUST BE USED. Check your local electrical code requirements before you make any connections.

INSTALLING GROUND WIRE

Ground the Alternator frame and Neutral leg to a solid earth ground. Follow local electrical code regulations enforced in your area with regard to neutral bonding to ground requirements. The ground wire should not be smaller than the load line. A ground stud terminal is supplied for this connection.

GEARBOX LUBRICATION

Check oil level. Fill with EP90 Gear oil if necessary. Maintain oil level slightly below check plug. DO NOT OVERFILL. Overfilling will cause heating and seal damage.

LAST CHECK BEFORE STARTING THE ALTERNATOR
Before starting the alternator for the first time, the unit should be inspected as follows:

1. Check electrical connections to load. (Refer to the electrical connection diagrams.)

2. Using the gearbox splined input shaft, turn the alternator manually and visually inspect for foreign objects that may have gotten into the unit during shipping and/or crating.

3. Check gearbox oil level.

4. Check alignment of PTO shaft.

5. Make sure all protective covers and guards are in place.

6. Make sure alternator input speed matches tractor pto speed.

OPERATING THE ALTERNATOR

1. Open the mainline circuit breaker or make sure the transfer switch is **NOT** in the emergency position. Starting the alternator with the load applied is not recommended.

2. When the alternator is used, **ALWAYS** start the tractor with the engine idling, engage the power take-off and let the clutch out slowly. Caution must be taken with electrically engaged power take-off drives. If engaged at higher than the idle or rated speeds, damage to the alternator or alternator gearbox will occur. Electrically engaged PTOs **MUST** be engaged at idle (approximately 800 RPM). Make certain the gearbox and alternator rotor turn freely.

3. Make certain unit is at rated speed and producing desired voltage. Procedures for reading speed monitor light and voltage are contained in the following paragraphs. Speed may dip slightly when load is applied and therefore, tractor throttle setting with full load applied may have to be increased slightly from no load setting. The load can now be applied to the alternator by closing the mainline circuit breaker or by transferring the transfer switch into the emergency position.

4. Speed Monitor. When the alternator is being driven at proper speed (1800 RPM), the Green light on the Speed Monitor will come on. At 1800 RPM, the alternator puts out 60 Hertz (60 cycles per second). The Green light goes off and the upper or lower red light comes on if the speed is too high or too low. The Green light stays on as long as the alternator output is between 59 and 61 Hertz. Motors will run satisfactorily if power frequency is within 5% of their nameplate value, as far as torque and heating are concerned. But note that on induction motors and synchronous motors, speed varies in proportion to frequency, hence any equipment that depends on frequency for timing will not be accurate if alternator speed is off.

5. Using the Speed Monitor.

a. When starting up the PTO Alternator, watch the Speed Monitor.

b. While the unit is coming up to speed, the bottom RED light will come on; continue to increase speed until the Green light comes on.

c. After load is applied, it may be necessary to readjust the speed to the green light position by increasing the tractor throttle.

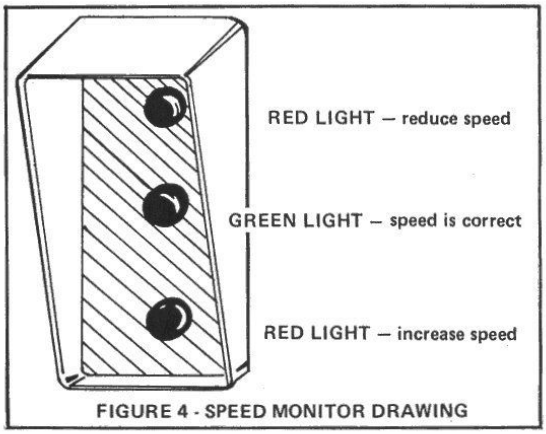

Figure 3

d. Check the Speed Monitor periodically while the unit is in operation, especially after adding or taking off load. If the top red light comes on, reduce speed; if the bottom red light comes on, increase speed. How to Verify Speed Light Operation.

Plug a standard analog wall clock into the 120-volt receptacle of the alternator. Run the generator and compare the second hand sweep around the face of the clock to the second hand of a wristwatch or stop watch. When the alternator is at 60 Hz the clock and wristwatch should match. If the clock runs faster than the wristwatch the alternator speed is too fast. If the clock runs slower than the wristwatch the alternator speed is too slow.

Speed Chart
61Hz = Clock will gain 1 second per minute of operation or 1 minute per hour of operation

59 Hz = Clock will lose 1 second per minute of operation or 1 minute per hour of operation.

6. Shutting the alternator down. Caution must be taken when disengaging the PTO driven alternator. To disconnect the electrical load prior to shutting down the alternator, open the mainline circuit breaker or make sure the transfer switch is **NOT** in the emergency position. Bring the tractor from rated speed to idle (approximately 800 RPM) before disengaging. Failure to follow this procedure could result in damage to alternator or alternator gearbox.

CAUTION:

DO NOT OPERATE TRACTOR IN NON-VENTILATED AREA.

STOP TRACTOR BEFORE FILLING WITH FUEL.

IN APPLICATIONS WHERE ALTERNATOR IS CONNECTED TO SERVICE WHICH IS NORMALLY SUPPLIED BY COMMERCIAL POWER, INSTALL A TRANSFER SWITCH. THIS PRECAUTION PROTECTS PERSONNEL SERVICING COMMERCIAL POWER LINES.

AVOID CONTACT WITH ALTERNATOR VOLTAGE. WHENEVER MAKING ELECTRICAL CONNECTIONS OR REPAIRING ALTERNATOR, FIRST STOP UNIT.

CHECKING ALTERNATOR OUTPUT VOLTAGE

To check the voltage, use a good quality AC Voltmeter - inexpensive meters often have an error of 10% or more. For best results, choose a meter that will indicate the desired voltage at about 3/4 of full scale, For example: to read 240 volts AC, use a 0 to 300 volt AC meter.

For personal safety, connect the meter to the generator before starting the engine.

WARNING: DANGEROUS VOLTAGES ARE PRESENT IN THIS UNIT!

VOLTAGE REGULATOR FUNCTION

Unless the alternator's output voltage is kept within narrow limits, equipment that is powered by it may not operate properly and may be damaged. Motors are usually designed to run satisfactorily only when the voltage at their terminals is within 10% of the nameplate value. In particular, motors will have their torque reduced and will overheat if they are operated at too low a voltage. If the voltage is too high it will cause some devices to burn out.

The purpose of the voltage regulator is to keep the alternator voltage at very near its set value. It does this by supplying the proper amount of direct current to the exciter field, according to the needs of the alternator. An increase in load normally causes the alternator voltage to decrease; the regulator senses this drop in voltage and increases the exciter field current just enough to bring the voltage back up. A decrease in load has the opposite effect - it causes the alternator voltage to go up; the voltage regulator senses this and reduces exciter field current so as to bring the alternator voltage back down to the set value.

The voltage regulator has an adjustment for setting the alternator voltage. This voltage is set at the factory and should require no further adjustment. However, should conditions exist which cause voltage output to change, voltage adjustment can be made with a screwdriver. Refer to the voltage regulator manual for instructions on voltage adjustment, regulator service, etc.

VOLTAGE REGULATOR REPLACEMENT

If the voltage regulator is defective it must be replaced and cannot be repaired. To reconnect properly, refer to the wiring diagram in the installation section. All connections are made at the terminal strip on the regulator.

EXCITER FIELD VOLTAGE

When there is a problem with the alternator, it is often useful to check the Voltage Regulator output to the exciter field. This voltage can be read at terminals F+ and F- on the regulator. The values should be taken from units running at rated speed (1800 rpm) and rated output voltage with NO LOAD. Exciter field voltage will normally be lower at no load than when the alternator is loaded. Note that DC meters are required to measure the exciter field voltage and current. Polarity must be observed.

ELECTRICAL SERVICE AND MAINTENANCE

ROTATING RECTIFIER ASSEMBLY MAINTENANCE AND TEST PROCEDURE

Individual rectifiers, or the complete rectifier assembly can be accessed by removing the end bracket opposite the drive end of the unit. Remove the end bracket to expose the bearing and rotating rectifier assembly for test, assembly or service, Refer to Figure 4.

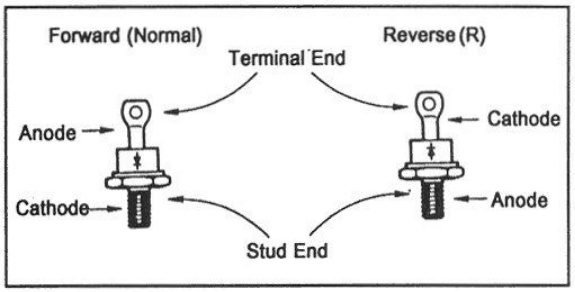

Figure 4

A. Stud type diodes may be tested in the field without unsoldering and removing the load from the diode terminal. Remove the diode load lead terminal lug from its terminal post, and insure that it is not making contact with any adjacent metallic part. An ohmmeter or a battery-light continuity tester may be used to find a short or open condition in the diode. Connect the positive test lead to the anode, and the negative
B. lead to the cathode, take a reading, reverse the test leads and take a reading. These checks should indicate one of three conditions:1. Good diode: Will have a much greater reverse resistance (positive lead on cathode) than forward resistance (negative lead on cathode). Typical reverse resistance will be 30,000 - 300,000 ohms or greater, while typical forward resistance will be less than 10 ohms. The continuity tester will have the light "on" in one direction, and "off"

in the other.

2. Shorted condition: ohmmeter reading will be zero, or very low in both directions. Continuity tester light will be on in both directions.

3. Open condition: ohmmeter will have a maximum (infinity) reading in both directions. Continuity tester light will be dark (off) in both directions.

CONSTANT EXCITATION (12V BATTERY) TEST

THEORY: The generator output voltage is dependent on generator speed, generator design, load, and exciter input current. If the generator speed and exciter input are known, the output voltage at no load can be measured and compared to the design value. Problems can be isolated to either the generator or regulator system by using this test.

TEST PROCEDURE:

1. Shut the generator set down.

2. Connect a voltmeter to the generator output.

3. Disconnect the F1 and F2 leads at the regulator.

4. Connect a 12 volt battery capable of supplying 1 amp to the F1 and F2 leads.

CAUTION: Beware of arcing when connecting leads. Stay clear of battery vents. Escaping hydrogen gas can explode. If hazardous conditions exist - use a suitable switch to connect or disconnect the battery.

5. With no load on the generator, (Main breakers open) run generator at rated speed (1800 rpm - 60 Hz or 1500rpm - 50 Hz).

6. Measure the generator output voltage.

7. Shut generator down.

8. Disconnect battery (see caution - Step 3).

Conclusion: If voltage output is near nominal, the main generator and exciter are operating properly. If voltage output is less than 50% of nominal, the problem is in the generator. Continue testing diodes, surge suppressor, windings.

REPLACEMENT OF DIODES

If a diode tests bad, replace all the diodes, or the complete rectifier assembly. Remove the diode leads to the main rotor terminal posts, along with the plastic lead wire clamps. The individual diodes are "stud type", retained by 1/3-20 hex head nuts and a lock washer. Prior to installing a replacement diode on the heat sink, run a bead of a thermal-electrical contact compound around the base of the diode. The threads should not be coated. Torque the diodes to 27-30 inch-pounds. Do not over tighten.

REPLACEMENT OF THE RECTIFIER ASSEMBLY

Remove the bearing from the main shaft. Disconnect the exciter rotor and main rotor leads. Remove the hold-down screws which secure the rectifier assembly to its mounting. The rectifier assembly is then free for removal.

To replace, reverse the procedure. Check all connections. Always install a new bearing.

RESTORING RESIDUAL MAGNETISM

The cores of the alternator and exciter fields retain a certain amount of magnetism after the power plant has been shut down. This residual magnetism must be present to begin the voltage build-up process when the power plant is started up again. If residual magnetism is lost due to a long idle period or some other cause, it well be necessary to flash the field. This is done by connecting a 12-volt battery across the exciter field for 15 - 30 seconds. Proceed as follows:

1. Disconnect the two exciter field leads from voltage regulator terminals F+ and F-. The field leads should be marked F2 and F1.

2. * Disconnect regulator power leads 3 & 4 from voltage regulator.

3. Connect the negative terminal of a 12 volt battery to lead F1.

4. Connect the positive terminal of the battery to lead F2 for a few seconds.

5. Start the engine and bring the unit up to speed.

6. There should be voltage at the alternator output - up to 200 volts AC line-to-line, more or less. If there is still no voltage, contact your local factory representative.

7. If voltage is now present, shut down the unit, disconnect the battery and connect the exciter field to the voltage regulator, F2 to F+ and F1 to F-.

8. Reconnect power leads 3 & 4.

9. Start up the engine and bring it up to speed; check output voltage.

* Refer to the voltage regulator manual for regulator connections, regulator operation, etc.

MECHANICAL
SERVICE AND MAINTENANCE

CLEANING

Do not permit ventilating ports to become clogged. Clean periodically.

REPLACING BEARINGS

Replacement bearings must be of the same size as originally installed at the factory. These procedures must be followed.

1. If the bearing requires replacement, the alternator endbell must be removed.

2. Replacement must be positioned on the shaft so that bearing inner ring is against the bearing shoulder on the shaft.

3. Bearings should be removed with a puller that applies pressure to the bearing inner ring.

4. Bearings are a press fit on the shaft. Replacement bearing should be heated to +220° to +250° F. in a clean, temperature controlled oven before attempting to install them on the alternator shaft.

5. A replacement bearing should be installed on the shaft while it is hot as described above. A sleeve or pipe that applies pressure to the bearing inner ring may be used to tap the bearing into place on the shaft. The sleeve or pipe should never exert pressure on the bearing outer ring.

ALTERNATOR DISASSEMBLY AND ASSEMBLY

Disassembly of alternator can be accomplished by following these steps.

1. Refer to cutaway drawing for location of parts.

2. Remove bolts securing gear cases to alternator. Carefully remove gear case from shaft. A jaw type puller may be required on older units.

3. Disconnect leads within alternator terminal box. Remove bolts holding terminal box to alternator.

4. Remove bolts holding endbells to alternator frame and stator assembly. Pull endbells.

5. Remove exciter armature by disconnecting leads. (Carefully cut ties holding leads to exciter armature windings).

6. Generator rotor can be removed from fan end without removing fan.

7. Do not remove exciter field from endbell unless it is to be replaced.

8. Do not remove bearings if they do not require replacement.

Assembly of the alternator can be accomplished by following these steps:

1. If new bearings are to be installed refer to preceding paragraphs titled Replacing Bearings.

2. If exciter field assembly was removed from end bell, install exciter field with lead wires toward endbell.

3. Slide alternator rotor into stator assembly.

4. Install endbells.

5. Install terminal box and reconnect wires. Refer to electrical diagrams contained in the Installation Section of this manual.

LUBRICATION

GEARBOX

Check gearbox fluid level at level check plug located in front gearbox case half at approximately an 8:00 position from the splined input shaft. Fluid level should be at thread level when the unit is setting on level. If low, fill with Std #80/90 weight gear lube. Katolight recommends that the PTO Alternator be brought up to full 1800 rpm operating speed at least twice annually to insure gearbox bearing and gear set lubrication.

PTO SHAFT

Grease PTO shaft needle bearings and tubular shaft assembly via grease zerts provided.

LOCATING TROUBLE

If the alternator does not appear to be producing voltage, check the load circuit breakers or fuses. If a circuit breaker is tripped, reduce the load and reset the breaker. If fuses are blown, replace the fuses. A common cause of poor alternator operation is underspeed.

Speed can be easily checked with a hand held frequency meter or tachometer.

The following Troubleshooting Chart lists various symptoms of poor alternator operation, possible causes and means of correcting deficiencies.

TABLE C
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
No Output Voltage.	Engine Speed too low.	Increase speed until alternator produces 60 cycles.
	Short Circuit in load.	Disconnect load. Check motors, appliances and load leads for short circuit.
	Open voltage regulator fuse.	Check voltage regulator fuse
	Defective receptacles.	Remove terminal box cover and test with test light.
	Loose terminal connections or shorted lead wires in control box.	Remove terminal box cover. Check terminal connections. Check for bare wires.
	Open fuses or circuit breakers.	Replace fuses. Reset circuit breakers.
	Voltage regulator defective.	Contact KATOLIGHT CORPORATION Sales and Service Office - Mankato, MN.
	Open or short circuited leads.	Remove alternator cover and check exciter field leads. Check leads from exciter armature to rotating rectifiers and alternator field coils. Make certain the tie down lacing holding exciter leads to shaft is securely wrapped and tied before placing unit back in operation.
	Open or short circuited exciter field coils exciter armature windings, alternator field coils or alternator stator windings.	Consult KATOLIGHT CORPORATION Sales and Service Office - Mankato, MN.

TABLE D
TROUBLESHOOTING CHART CONTINUED

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Low Voltage	Engine speed too low.	Increase engine speed until alternator produces 60 cycle output.
	Voltage adjust rheostat not properly adjusted.	Adjust to rating.
	Alternator Overloaded.	Reduce load to rated value. Make certain alternator is not overloaded by unbalanced load.
	Short circuit in load.	Remove load. Check appliances and motors for point of short circuit.
	Defective voltage regulator or rotating rectifiers.	Consult KATOLIGHT CORPORATION Sales and Service Office - Mankato MN if voltage regulator is defective. Test rotating rectifiers.
High Voltage	Voltage adjust rheostat not set correctly.	Adjust to proper voltage.
	Defective voltage regulator.	Contact KATOLIGHT CORPORATION Sales and Service Office - Mankato MN.
Poor Voltage Regulation	Load in excess of alternator rating.	Reduce load. Check nameplate rating.
	Wrong alternator speed or defective regulator.	Correct speed. Replace regulator.
Continuous Voltage Fluctuation	Engine speed not constant.	Engine may not have enough power or engine governor may be worn or improperly adjusted. Set or repair defective governor.
	Defective Regulator.	Adjust voltage stability pot (CW to increase stability) if fails then consult KATOLIGHT CORPORATION Sales and Service Office - Mankato MN.
Vibration & Noise	Defective bearings.	Replace bearings.
	Gearbox dry or overfilled.	Check gearbox oil level.
	Power take-off misalignment excessive or universal joint dry or worn.	Correct defects. Refer to Operation section of this manual for alignment procedures.
	Loose mounting bolts.	Check or tighten as necessary.

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order:

1. Always give SERIAL NUMBER, and MODEL NUMBER.

2. Give the item part number and description. Give the quantity required of each item. DO NOT ORDER BY REFERENCE NUMBER OR GROUP NUMBER. If an old part cannot be identified return the part POSTAGE PREPAID to your distributor or KATOLIGHT CORPORATION. Write a letter to the same address stating the reason for returning the part.

Crimping

Full Load Connector Plug
Installation Tips

The following guidelines are recommended for optimizing the assembly of connectors.

1. Contact your nearest Katolight Corporation representative to obtain the proper assembly tools.

2. Reference the assembly instruction specific to the connector. Assembly instructions for a connector can be obtained from your nearest Katolight Corporation representative.

3. Reference all applicable electrical standards requirements such as NEC, UL, CSA etc.

4. Perform a sample assembly of a few pieces for assembly verification testing. Test these samples for proper crimp dimensions, secureness, crimp resistance, connected resistance, and operating temperature. Contact your nearest Katolight Corporation representative for recommended specifications for these parameters.

5. Perform periodic assembly verification testing to assure assembly process and tooling are performing correctly. Normally, crimp dimensions are checked at shorter intervals and crimp resistance and secureness are checked at longer intervals. The intervals are dependent upon the tooling, the wire and the connector being used.

Important Assembly Notes:

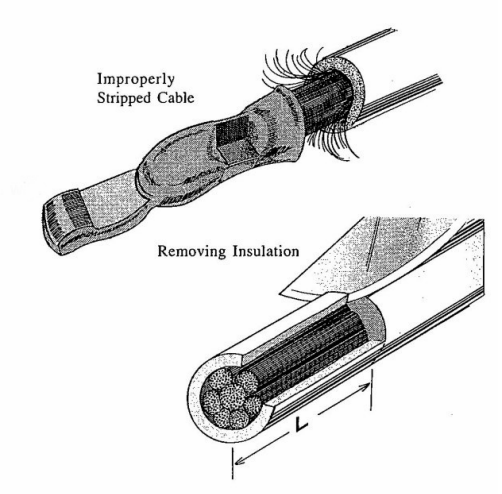
Proper crimping and cleaning of the wire is essential for optimizing connector service.

If the proper crimp has been performed, the secureness is satisfactory but the crimp resistance is high (which may cause high operating temperatures) the wire may have surface contamination. A light abrasive such as the 3M Scotch Brite ™ is recommenced for
cleaning the wire.

Please Note: Tin-plated wire resists surface contamination caused by oxidation.

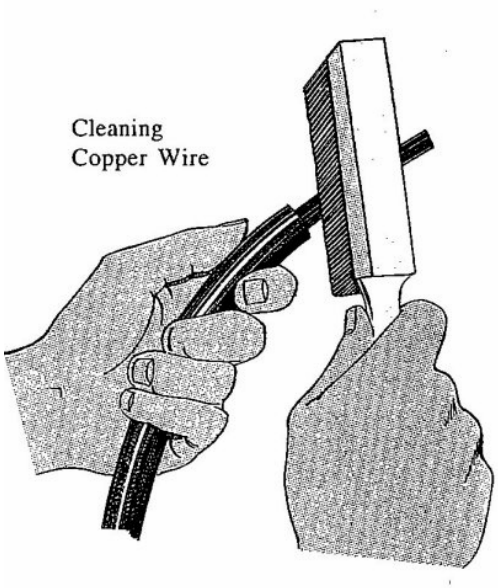
Connector Crimping & Soldering

1. Stripping Cable Insulation



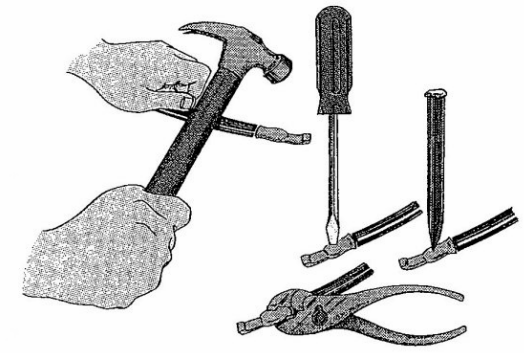
Problems with cable harness and connector systems often begin with improper or accidental cutting of wire strands when stripping cable insulation. Each strand is important, and all of them must be included in the contact barrel to avoid unnecessary hot spots during later operation. When removing insulation, position a sharp blade at a right angle and apply steady, controlled pressure, cutting only the cable insulation, not the copper wire. Strip cable to the right length for the contact being crimped.

2. Cleaning Copper Wire



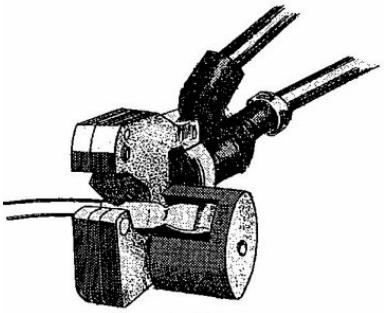
Aged and badly tarnished copper wire should be thoroughly scraped with a stiff wire brush that penetrates the entire bundle and cleans every strand. The wires are ready for insertion into the contact barrel when they are burnished to their original bright copper finish. Contact barrels are lined with silver plating to assure consistently high conductivity, which will be reduced if the barrel is crimped around aged or tarnished copper wire.

3. Crimping



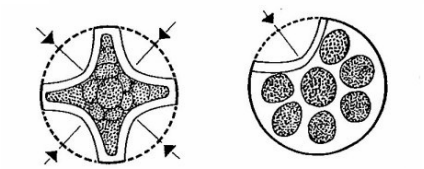
The best preparation will be defeated if inadequate tools or improper crimping procedures are employed. Never use a hammer and chisel or the “squeeze-in-a-vise” method. They won’t do the job, and will lead directly to substantial reduction in connector life.

Use a crimping tool. It effectively compresses the contact barrel tightly around the cable strands so that all of them are pressed tightly against each other and the inside wall of the contact barrel. Doing this requires that the stripped cable be inserted all the way into the barrel of the contact, and that the contact point is centered in the crimping tool.



Pneumatic Crimp

When the crimp has been completed, check the appearance of the contact. A properly crimped contact barrel is compacted tightly with the outer strands. The outer strands on an improperly crimped barrel will be loose and will not have adequate clamping force. Test for low pull-out force by giving the cable a tug. If the cable can be loosened, recrimp until it is tight.



Properly Crimped

Improperly Crimped
(Contains air pockets)

4. Soldering

The alternative to crimping is to solder all cable strands within the contact barrel. The right proportion of solder is essential if this procedure is employed. Use a quality 60/40 solder (60 percent tin, 40 percent lead) in wire form with a rosin flux core. Cable strands should be separately fluxed with rosin paste, and the contact should be held in a vise with the barrel entrance facing up. Apply heat to the outside of the barrel while the solder flows in beside the wire strands.

Here are some things to avoid when soldering:

A. Don't use too much solder – to the point that it flows out of the contact barrel.
B. Don't allow flux or solder on the outside of the contact. This will interfere with contact mounting within the installation or with the contact connection to a mating connector.
C. Don't overheat and cause excessive solder to "wick" up into the cable and stiffen it. This could interfere with contact flexibility when connectors are mated.
D. Don't solder when contact is in the connector housing. Solder away form the housing and then insert the contact into the housing.

Note: Underwriter Laboratories (UL) requires the use of a cable clamp for soldered connections to unsupported leads.

5. Inserting Contact into Housing

Contacts should never be forced into housing. If the contact does not fit easily, check the contact barrel for distortion. Replace the barrel if it is distorted or shows signs of wear or damage.

Preventive Maintenance

Damaged connectors, contacts and cables may present hazard. To avoid these problems, conduct the following maintenance checks at least once annually. When you see a problem, take corrective action immediately.

1. Dirty Connectors

When engaged and disengaged, the crown contact surfaces "over-wipe", thus providing a self-cleaning action. To ensure the continued benefit of the feature, clean the contact surfaces.

2. Melting Connectors

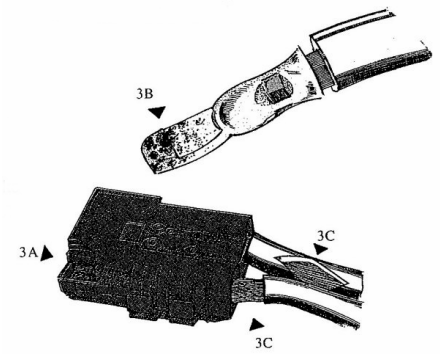
Connector housings overheat and melt for many reasons. To prevent this:

A. Examine the crimp between cable and contact. Improper crimping, corrosion, and broken wires result in unnecessary resistance causing the contact to heat up like a toaster.
B. Check contact crown surfaces for signs of "pitting" caused be dirt or disengaging connectors under load.

3. Other Conditions

If any of the following conditions exist, the connector housing, contact and / or cable should be replaced immediately.

A. **Housing:** Cracks, missing pieces, evidence of excessive heat, discoloration.
B. **Contacts:** Pitting, burns, corrosion, excessive wear, cracked crimp barrels, discoloration.
C. **Cable:** Exposed copper near housing, cracked cable, peeling or frayed insulation.
D. **Handles:** Loose attachment and such signs of damage as missing or loose hardware and cracked or broken plastic. (Handles should be used for connectors that are hard to reach or move.)



E. **Cable Clamps:** Loose attachments, signs of abraded cable jacket, missing or loose hardware. (Cable clamps should be used to relieve strain on unmounted cable.)

Terminology

Applicator	A semi-automatic installation machine consisting of an upper and lower half that is used to crimp contacts onto wire. Used in conjunction with an electrical / mechanical press.
AWG	American Wire Gauge. A standard system for designating wires diameters.
Blindmate	to join two connector halves in a normal engaging mode without visual orientation.
Color Coding	A system of identification for terminals and related devices.
Contact Resistance	The electrical resistance of metallic surfaces at their interface in the contact area under specified conditions when carrying a specified test current. Overall contact resistance includes wire to wire measurement.
Contact Retention	Minimum axial load in either direction which a contact must withstand while remaining firmly fixed in its normal position within a housing.
Crimp Retention	The axial load which a contact can withstand without separation for the wire.
Crimp Termination	A connection in which a metal sleeve is secured to a conductor by mechanically deforming the sleeve with presses, or automated crimping machines, eliminating the need for solder. Suitable for all wire types.
Cycle Controlled Crimp Tool	A type of crimp tool that requires the crimp cycle be completed before the tool releases the contact. A cycle controlled tool ensures that proper mechanical pullout and proper crimp resistance values are achieved.
Detent	A bump or raised section projecting from the surface of a contact for keeping the contact in position relative to another and released by greater force.

Dielectric Strength (Withstanding Voltage)	The highest potential difference (voltage) that an insulation material of given thickness can withstand for a specified time without occurrence of electrical breakdown through its bulk.
Finger Proof	A connector intended for usage external to the end equipment shall have live parts protected against exposure to contact by persons when assembled, installed and mated as intended as determined by UL Articulated probe.
Flammability	The measure of a material's ability to support combustion. Often tested per UL 94
Flat Wiping	The sliding action which occurs when contacts are mated. Wiping has the effect of removing small amounts of contamination from the contact surfaces, thus establishing better conductivity.
Heat Rise	Temperature rise associated with the electrical load applied to a mated connection.
Hermaphroditic (Genderless) Connector	A connector in whom both mating members are exactly alike at their mating face. There are no male or female members, but designs provide correct polarity.
Insulation Resistance	Ratio of applied voltage to the total current between the two Electrodes in contact with a specific insulation.
Locator	Device for positioning contacts into crimping dies.
Make First / Beak Last (Sequencing)	Protective measure against excess currents short-circuits and ground faults by contacts used to interrupt the fault current flow before connector mating.
Mating Force	Force required joining two connector halves in a normal engaging mode.
Mechanical Keys	The use of a mechanical feature that assures that the coupling of identical mating components can occur in only one direction.

Modular	Refers to similar parts or modules used as building blocks. A modular connector is one in which similar or identical sections can be assembled together to provide the appropriate connector type or size for the application.
Operating Temperature Range	Connector temperature rating established by materials used; plastic, finish and the base metal. Applying an electrical load will result in a temperature rise that is additive to the operating ambient.
Polarization	A technique of eliminating symmetry so that parts my only be mated one way.
Pulse (Surge) Current	Highest instantaneous current that will run through a system.
Reducing Bushing	Separate tubular sleeve used to downsize the diameter of a crimp barrel for a smaller size wire.
Reeled Contacts	Contacts attached to a feeder strip for use in a high volume crimping tool.
Self Wiping	The sliding action which occurs when contacts are mated. Wiping has the effect of removing small amounts of contamination form the contact surfaces, establishing better conductivity.
Spring Loaded	A means of providing contact normal force with the use of a mechanical spring.
Strain Relief	A means of termination or installation that reduces the transfer of mechanical stress from the conductor.
Termination	Means of joining contacts to a conductor.

ALTERNATOR DATA

The alternators described in this manual are single phase, 120/240 VAC, 1800 RPM revolving field brushless type with Automatic Voltage Regulation. Output voltage may be varied by turning the voltage adjust potentiometer.

Standard equipment includes: Speed Monitor Light, Automatic Voltage Regulator, Brushless Revolving Field Type Alternator, Mainline Circuit Breaker, 15 Amp, 120 Volt 3 Wire Duplex Receptacle, 50 Amp 240 Volt 4 Wire Receptacle, Full Load Connector, Safety Shield, Lifting Eyes, Helical Gears, Mounting Base, Gear Lube, Grounding Terminal, 1800 RPM Slow Speed, Rodent Screen & Drip Proof Design.

Important data pertinent to your alternator is given on the nameplate attached to the alternator. Additional information is contained in Table A. For handy reference, copy your plant nameplate information in the spaces to the left.

TABLE A

INTRODUCTION

Before any Katolight PTO Driven Alternator is shipped from the factory the alternator is inspected and tested for performance. No unit is shipped unless it produces its rated capacity. Carefully unpack the unit and visually inspect it for damage. If it is damaged, check with the transportation carrier for adjustment of the damage. Before placing the unit in operation, check to make sure that the lubrication is in the gearbox. If empty, remove level check plug and fill with EP90 weight gear oil to check plug level.

If upon installation a new alternator does not work properly, check all electrical connections and the alternator speed before concluding the alternator is defective.

DETERMINING YOUR SPECIFIC LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor which will be operated by the unit. The following chart lists approximate running or operating watts required for various electrical appliances.

TABLE B
APPROXIMATE WATTS REQUIRED
FOR ELECTRICAL APPLIANCES

APPLIANCE	WATTS
Lamp Bulbs	See wattage on bulbs
Radio	40-200
Television	150-300
Vacuum Cleaner	200-750
Automatic Washer	400
Air Conditioner (¾ Ton)	1,250
Refrigerator	325
Food Freezer	300
Furnace (Oil)	700
Deep Well Pump	2,000
Electric Range	600-10,000
Hot Plate (per burner)	600-1,200
Toaster	600-1,130
Water Heater	1,500-5,000
Glow Heater	600-1,200
Heating Pad	40-80
Sun Lamp	250-1,000
Flat Iron	600-1,200
Laundry Dryer	4,750
Electric Heat System	5,000-20,000

Check all appliance nameplates for exact ratings.

HOW ELECTRIC MOTORS ARE CLASSIFIED, AND WHAT THEIR RATINGS MEAN

Electric motors require more current (amperes) starting than running. Split-phase motors are difficult to start and require 5 to 10 times as much current to start as to run, dependent on the NEMA code letter rating. Capacitor motors require 2 to 4 times as much current to start as to run. Repulsion Start Induction Motors require 1½ to 2½ times as much current to start as to run.

The chart below shows the approximate current required to run and start 120 volt, 60 cycle, NEMA Code F induction motors under average load conditions.

Horse Power	Running Amperes	Starting Amperes
1/6	4.4	7 to 15
1/4	5.8	10 to 15
1/3	7.2	15 to 25
1/2	9.8	20 to 30
1	16.0	40 to 50

The NEMA code letter assigned by the motor manufacturer will govern the starting (locked rotor) current surge. The chart below shows the NEMA code letters and their corresponding range of multipliers for the starting current requirement in amperes.

NEMA Code letter Motor Rating	Kilovolt-Amperes per Horsepower (Locked Rotor)
A	0 – 3.14
B	3.15 – 3.54
C	3.55 – 3.99
D	4.0 – 4.49
E	4.5 – 4.99
F	5.0 – 5.59
G	5.6 – 6.29
H	6.3 – 7.09
J	7.1 – 7.99
K	8.0 – 8.99
L	9.0 – 9.99
M	10.0 – 11.19
N	11.2 – 12.49
P	12.5 – 13.99
R	14.0 – 15.99
S	16.0 – 17.99
T	18.0 – 19.99
U	20.0 – 22.39
V	22.4 – and up

Here is a formula for amps:

The starting current for 1 h.p.
Code F 230 V.A.C.

$$1 \times 5.6 = 5.6 \text{ KVA}$$

$$\text{Amp} = \frac{\text{KVA}}{\text{Volts}} = \frac{5.6^{10^3}}{230} = 24.3 \text{ amp}$$

Because the heavy surge of current required for starting motors is needed only for an instant, the alternator will not be damaged if it can bring the motor up to speed in a few seconds. If difficulty is experienced in starting motors, turn off all other electircal loads and, if possible, reduce the load on the electric motor.

NOTE

IN APPLICATIONS WHERE SEVERAL MOTORS ARE TO BE STARTED, EXCESSIVE OVERLOAD MAY BE AVOIDED BY STARTING THEM ONE AT A TIME. START THE MOTOR THAT REQUIRES THE HIGHEST RUNNING AND STARTING CURRENT FIRST.

INSTALLING THE ALTERNATOR

Provide sufficient ventilation. Do not operate tractor driven alternator in a non-ventilated area. Do, however, provide protection from heavy snow or dust which may plug air cleaners and ventilation openings.

For best operation the following factors should be taken into consideration:

1. Dirt — Dust particles and dirt can cause excessive wear, not only to bearings but to all rotating parts of the alternator.

2. Moist or wet conditions are hazardous. In addition, all electrical equipment should be protected from excessive moisture which deteriorates insulation and causes short circuits.

The generator must be stored properly. Protect it from moisture and dirt. If the unit is to be left in the open, it should be covered whenever it is not in use. All ventilating openings should be cleaned periodically and kept clear and open while operating.

MOUNTING THE ALTERNATOR

The alternator must be solidly bolted to a foundation, platform or bed of a trailer. All four feet on the alternator must contact the foundation or trailer bed. If space is left between a mounting foot and the foundation or trailer, shim it to take up the space and then insert and tighten bolts.

ALIGNING ALTERNATOR WITH TRACTOR POWER TAKE-OFF

The double universal joint construction of the power take-off drive shaft allows for considerable angular misalignment between the gearbox and the tractor power take-off shaft. As shown in Figure 1 the angular misalignment of the universal joints, if at all possible, should not be more than 15 degrees. If the power take-off drive shaft is taken apart, make certain the drive shaft universal joint knuckles are in time with one another as shown in Figure 2. If the drive shaft universal joint knuckles are not in time chattering will occur which will cause a flicker in the electrical output. The same flicker will also occur if the angle of the drive shaft from the alternator to the tractor power take-off is more than 15 degrees. Make certain the power take-off shaft lock pin is properly engaged and the removable power take-off shaft shields are installed before operating the unit.

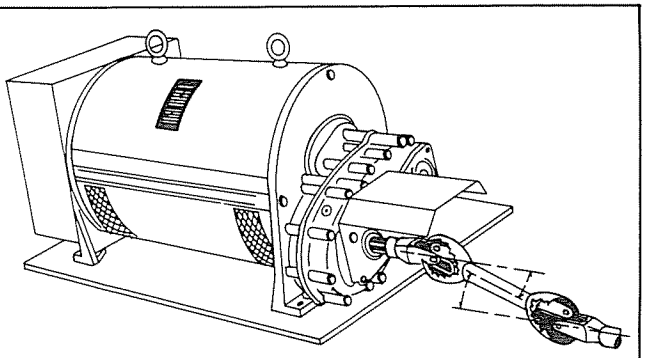

FIGURE 1 - TRACTOR DRIVE GENERATOR CONNECTED TO TRACTOR POWER TAKE-OFF

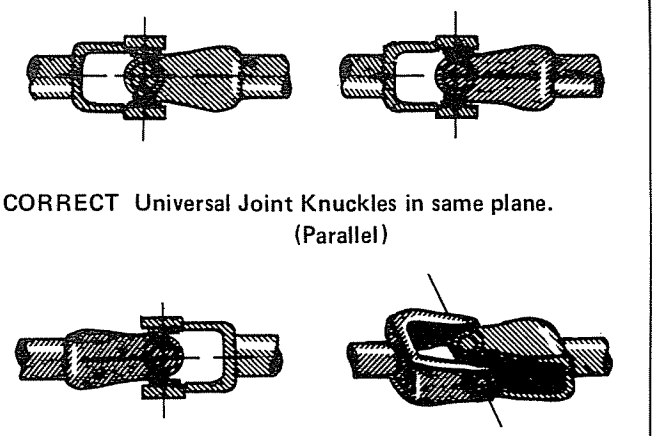

CORRECT Universal Joint Knuckles in same plane. (Parallel)

INCORRECT Universal Joint Knuckles NOT in same plane (Not Parallel)

FIGURE 2 - ALIGNING POWER TAKE-OFF SHAFT UNIVERSAL JOINTS

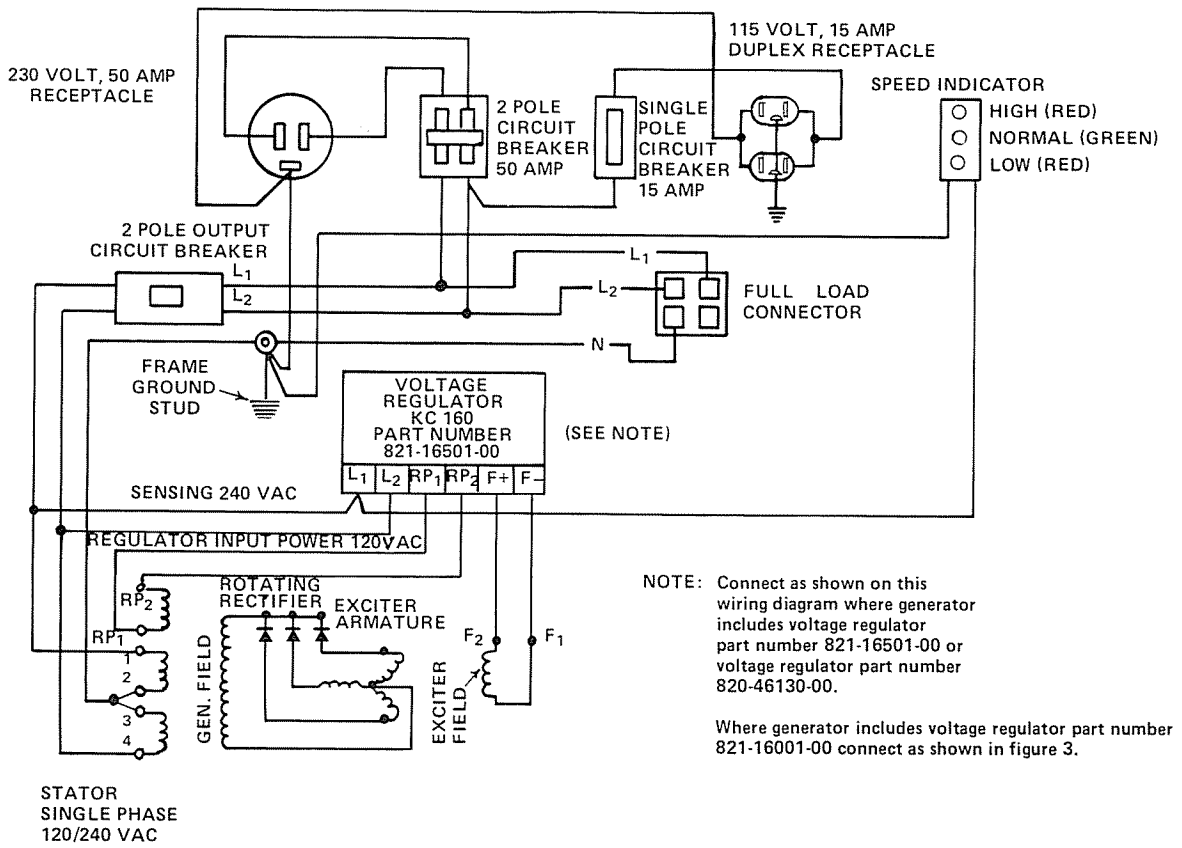

Figure 2 Wiring Diagram, LR1 Generator with Voltage Regulator Part Number 821-16501-00 or 820-46130-00

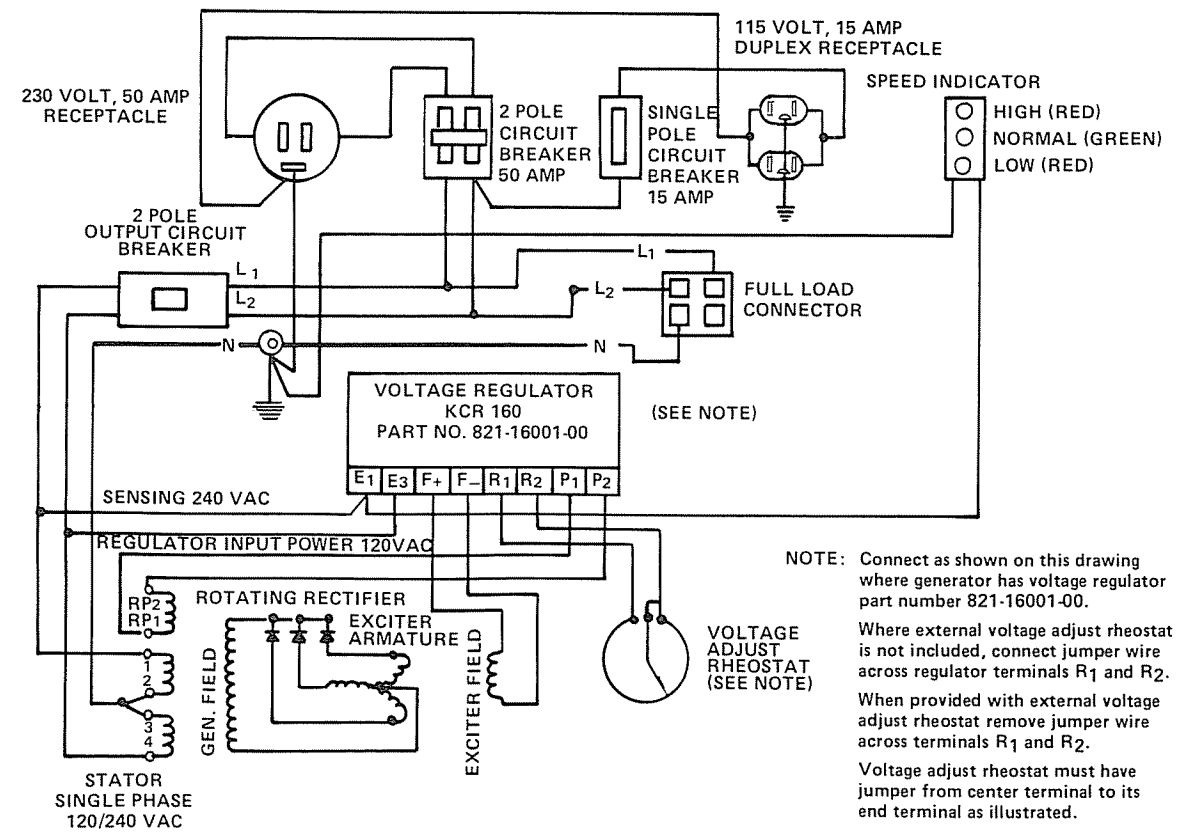

Figure 3 Wiring Diagram LR1 Generator with Voltage Regulator Part Number 821-16001-00

CONNECTING ALTERNATOR TO LOAD

* Load can be taken from recepticals or by connecting the Alternator into an existing service through the full load connector plug.
* Load taken from recepticals should not exceed the respective receptical rating and should never exceed the alternator rating. The 120 VAC duplex receptical is rated for 15 amps and the 240 VAC receptical is rated at 50 amps. Both recepticals and the full load plug are protected by individual overload protection circuit breakers.
* Load taken from the 240 VAC full load cord set should not exceed the full load rating of the alternator.
* When the Alternator is connected into an existing service normally supplied by commercial power an approved TRANSFER SWITCH MUST BE USED. Check your local electrical code requirements before you make any connections.

INSTALLING GROUND WIRE

Ground the Alternator frame and Neutral leg to a solid earth ground. The ground wire should not be smaller than the load line. A ground stud terminal is supplied for this connection.

GEARBOX LUBRICATION

Check oil level. Fill with EP 90 Gear oil if necessary. Maintain oil level slightly below check plug. DO NOT OVERFILL. Overfilling will cause heating and seal damage.

LAST CHECK BEFORE STARTING THE ALTERNATOR

Before starting the alternator for the first time, the unit should be inspected as follows:

1. Check electrical connections to load. (Refer to the electrical connection diagrams.)

2. Remove cover surounding alternator. Turn rotor manually and visually inspect for foreign objects that may have gotten into the unit during shipping and/or uncrating.

3. Check gearbox oil level.

4. Check alignment of PTO shaft.

5. Make sure all protective covers and guards are in place.

OPERATING THE ALTERNATOR

1. Open the mainline circuit breaker or make sure the transfer switch is "Not" in the emergency position. Starting the alternator with the load applied is not recommended.

2. Start Tractor and Engage PTO.

3. Make certain unit is at rated speed and producing desired voltage. Procedures for reading monitor light and voltage are contained in the following paragraphs. Speed may dip slightly when load is applied and therefore, tractor throttle setting with full load applied may have to be increased slightly from no load setting. The load can now be applied to the alternator by closing the mainline circuit breaker or by transfering the transfer switch into the emergency position.

4. Speed Monitor. When the alternator is being driven at proper speed (1800RPM), the Green light on the Speed Monitor will come on. At 1800 RPM, the alternator puts out 60 Hertz (60 cycles per second). The Green light goes off and the upper or lower red light comes on if the speed is too high or too low. The Green light stays on as long as the alternator output is between 59 and 62 Hertz.

   Motors will run satisfactorily if power frequency is within 5% of their nameplate value, as far as torque and heating are concerned. But note that on induction motors and synchronous motors, speed varies in proportion to frequency, hence any equipment that depends on frequency for timing will not be accurate if alternator speed is off.

5. Using the Speed Monitor.

   a. When starting up the power plant, watch the Speed Monitor.

   b. While the unit is coming up to speed, the bottom RED light will come on; continue to increase speed until the Green light comes on.

   c. After load is applied, it may be necessary to readjust entire speed.

   d. Check the Speed Monitor periodically while the unit is in operation, especially after adding or taking off load. If the top red light comes on, reduce speed; if the bottom red light comes on, increase speed.

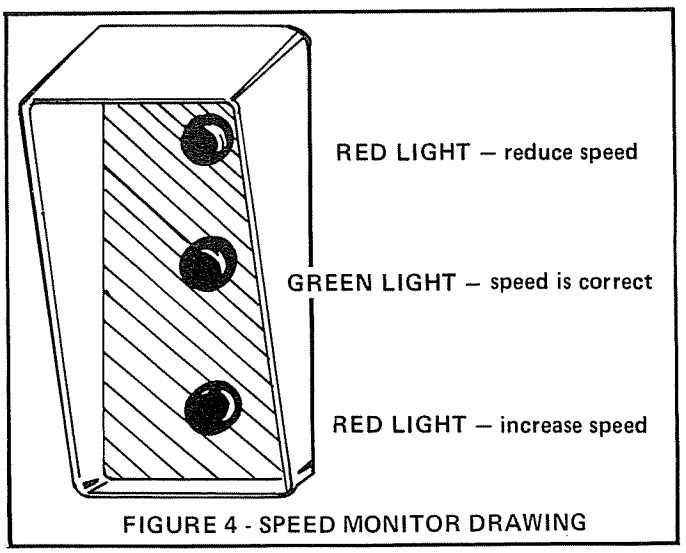

FIGURE 4 - SPEED MONITOR DRAWING

6. When the alternator is used in extremely cold weather, start the tractor and with the tractor idling, engage the power take-off and let the clutch out slowly. Make certain the gearbox and alternator rotor turn freely.

7. FINAL CAUTION:
DO NOT OPERATE TRACTOR IN NON-VENTILATED AREA.

STOP TRACTOR BEFORE FILLING WITH FUEL.

IN APPLICATIONS WHERE ALTERNATOR IS CONNECTED TO SERVICE WHICH IS NORMALLY SUPPLIED BY COMMERCIAL POWER, INSTALL A TRANSFER SWITCH. THIS PRECAUTION PROTECTS PERSONNEL SERVICING COMMERCIAL POWER LINES.

AVOID CONTACT WITH ALTERNATOR VOLTAGE. WHENEVER MAKING ELECTRICAL CONNECTIONS OR REPAIRING ALTERNATOR, FIRST STOP UNIT.

CHECKING ALTERNATOR OUTPUT VOLTAGE

To check the voltage, use a good quality AC Voltmeter—inexpensive meters often have an error of 10% or more. For best results, choose a meter that will indicate the desired voltage at about ¾ of full scale. For example: to read 240 volts AC, use a 0 to 300 volt AC meter.

On the alternators described in this manual, the line-to-neutral voltage (line 1 [L1] to neutral [N] or L2 to neutral) is one half of the line-to-line voltage (L1-L2). If the two line-to neutral voltages are not equal, it could be due to unbalanced load, a grounded wire, a bad connection, or to a defect in the stator windings.

For personal safety, connect the meter to the generator before starting the engine.

WARNING: DANGEROUS VOLTAGES ARE PRESENT IN THIS UNIT!

ALTERNATIVE METHOD OF CHECKING FREQUENCY

Alternator frequency can be checked with an electric clock and a watch. They should have sweep second hands. Plug an electric clock into the 120 volt receptacle on the alternator. If the second hand on the electric clock moves at the same rate as the second hand on the watch, generator frequency is correct. If the clock lags behind the watch, engine speed is too low; if the clock moves ahead of the watch, the engine is running too fast.

VOLTAGE REGULATOR FUNCTION

Unless the alternator's output voltage is kept within narrow limits, equipment that is powered by it may not operate properly and may be damaged. Motors are usually designed to run satisfactorily only when the voltage at their terminals is within 10% of the nameplate value. In particular, motors will have their torque reduced and will overheat if they are operated at too low a voltage. If the voltage is too high it will cause some devices to burn out.

The purpose of the voltage regulator is to keep the alternator voltage at very near its set value. It does this by supplying the proper amount of direct current to the exciter field, according to the needs of the alternator. An increase in load normally causes the alternator voltage to decrease; the regulator senses this drop in voltage and increases the exciter field current just enough to bring the voltage back up. A decrease in load has the opposite effect—it causes the alternator voltage to go up; the voltage regulator senses this and reduces exciter field current so as to bring the alternator voltage back down to the set value.

The voltage regulator has an adjustment for setting the alternator voltage. This voltage is set at the factory and should require no further adjustment. However, should conditions exist which cause voltage output to change, voltage adjustment can be made with a screwdriver on the R2 adjustment. See regulator layout in Figure 5.

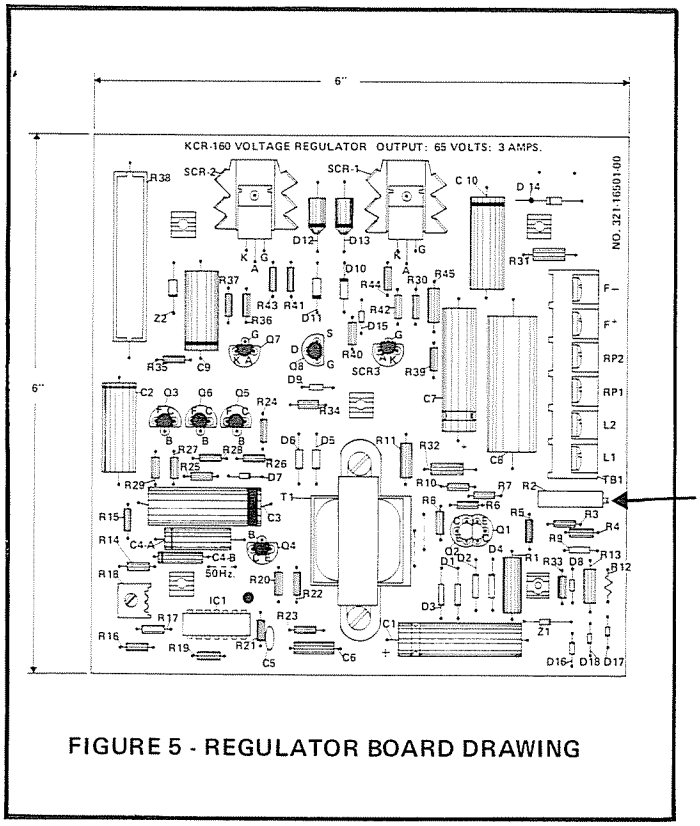

FIGURE 5 - REGULATOR BOARD DRAWING

VOLTAGE REGULATOR REPLACEMENT

If the voltage regulator is defective it is advisable to replace the entire circuit board assembly. To reconnect properly, refer to the wiring diagram in the installation section. All connections are made at the terminal strip on the regulator.

EXCITER FIELD VOLTAGE

When there is a problem with the alternator, it is often useful to check the Voltage Regulator output to the exciter field. This voltage can be read at terminals F+ and F— on the regulator. The values in Table C were taken from units running at rated speed (1800 rpm) and rated output voltage (240 VAC) with NO LOAD. Exciter field voltage will normally be higher than the tabled value when the alternator is loaded. Note that DC meters are required to measure the exciter field voltage and current. Polarity must be observed.

TABLE C
EXCITER FIELD VOLTAGE AND CURRENT

25LR1	14.0 Volts DC	.25 Amp
35LR1	14.0 Volts DC	.25 Amp
45LR1	18.0 Volts DC	.28 Amp
55LR1	24.0 Volts DC	.31 Amp
85LR1	28.0 Volts DC	.41 Amp

ELECTRICAL SERVICE AND MAINTENANCE

TESTING THE ROTATING RECTIFIER OR DIODE

A rotating rectifier changes the AC that is generated in the exciter armature to DC which is required for the alternator field. The rotating rectifier consists of three individual rectifier diodes. Each individual diode has two terminals. The diodes are threaded into the sleeve shaft of the exciter armature; this makes it possible to test the rectifier diodes with a 3 volt DC test lamp as shown in Figure 6. Figure 6 shows the test being made with the diode removed entirely from the circuit. It is possible, however, to test the rectifier without disassembling it.

1. Stop the alternator and remove the cover from the outlet box.

2. The connection between the alternator field and the exciter armature can be seen on the exciter armature: the wires are bolted together, covered with an insulating sleeve, and bound to the armature with plastic tie wraps. Note the position of this connection so that is can be restored properly later. Cut and remove the tie wraps, being very careful not to damage the armature; remove the sleeve and open the connection.

3. Test each diode as shown in Figure 6.

   a. Open diode. If any diode does not pass current as it should, replace it. Refer to the paragraph on Removing and Installing Diodes.

   b. Shorted diode. If one of the diodes is shorted, it will be difficult to identify it without unsoldering the diode connections. If a short is indicated, unsolder and test diodes one by one until the shorted diode is found.

4. After making sure that good diodes are installed, restore all connections. For securing the alternator field connection, obtain plastic tie wraps similar to the ones installed at the factory and be careful not to damage the armature winding when tying down the wires.

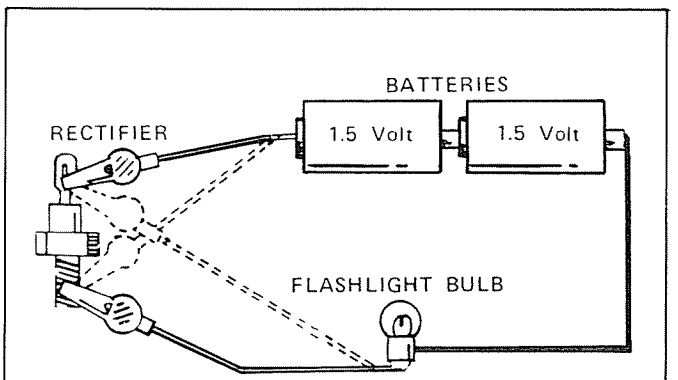

FIGURE 6—TESTING ROTATING RECTIFIERS WITH TEST LIGHT

REMOVING AND INSTALLING DIODES

The diodes are rugged and will easily withstand the stresses of normal operation, but they can be damaged during removal or installation unless it is done carefully.

1. Do not try to turn the diode without first unsoldering it, since a twisting force on the solder terminal could damage the diode internally.

2. When soldering or unsoldering, do not use any more heat than necessary. The diode can be protected from excessive heat by applying a clip-on heat sink or a long-nosed pliers on the terminal between the soldering iron and the body. of the diode.

3. Do not use excessive force when screwing the diode into its mounting. Considerably less force is required here than in tightening bolts of similar size.

RESTORING RESIDUAL MAGNETISM

The cores of the alternator and exciter fields retain a certain amount of magnetism after the power plant has been shut down. This residual magnetism must be present to begin the voltage build-up process when the power plant is started up again. If residual magnetism is lost due to a long idle period or some other cause, it will be necessary to flash the field. This is done by connecting a 12-volt battery across the exciter field for 15 - 30 seconds. Proceed as follows:

1. Disconnect the two exciter field leads from voltage regulator terminals F+ and F—. The field leads should be marked F2 and F1. See Figure 7.
2. Disconnect regulator power lead RP1 from voltage regulator.
3. Connect the negative terminal of a 12 volt battery to lead F1.
4. Connect the positive terminal of the battery to lead F2 for a few seconds.
5. Start the engine and bring the unit up to speed.
6. There should be voltage at the alternator output—up to 200 volts AC line-to-line, more or less. If there is still no voltage, contact your local factory representative.
7. If voltage is now present, shut down the unit, disconnect the battery and connect the exciter field to the voltage regulator, F2 to F+ and F1 to F—.
8. Reconnect power lead RP1.
9. Start up the engine and bring it up to speed; check output voltage.

FIGURE 7

CAUTION! Exercise extreme caution at all times. Insulate or isolate all AC leads. They are extremely hazardous. Do NOT touch them or allow them to touch anything!

Approximate AC output voltage using 12 volt DC battery as exciter field power.

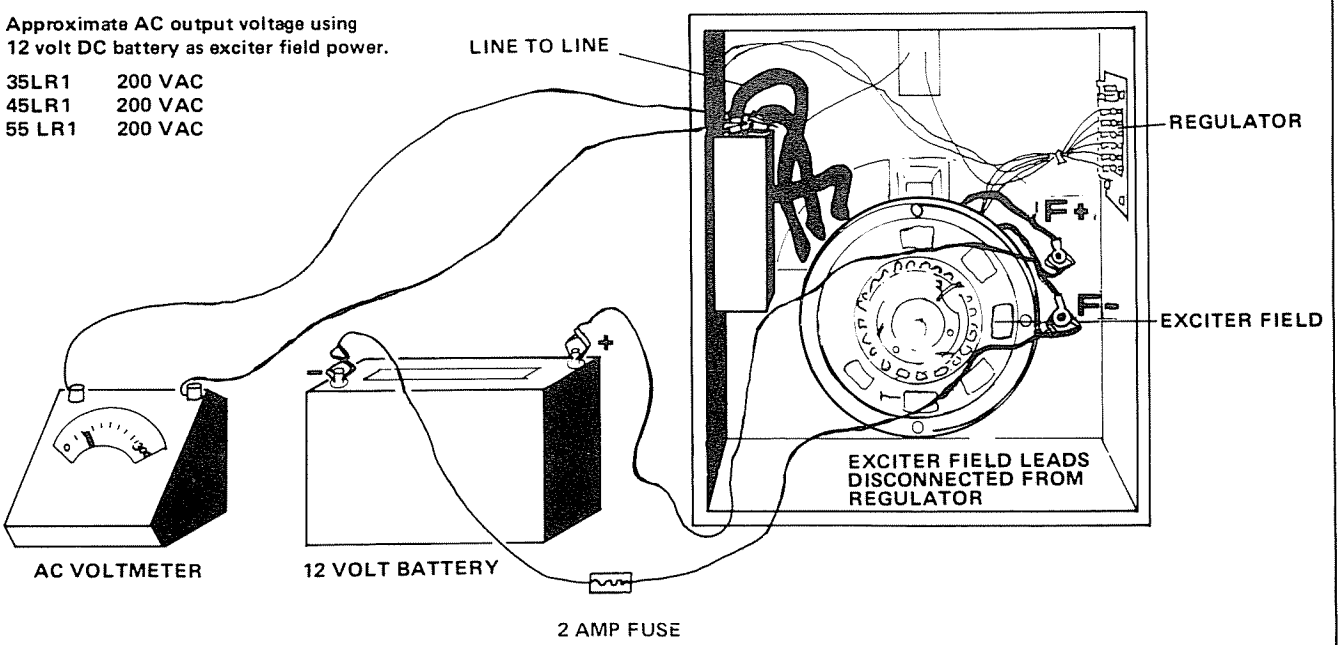
55 LR1	200 VAC



MECHANICAL SERVICE AND MAINTENANCE

CLEANING

Do not permit ventilating ports to become clogged. Clean periodically.

REPLACING BEARINGS

Replacement bearings must be of the same size as originally installed at the factory. These procedures must be followed.

1. If the bearing requires replacement, the terminal box and alternator endbell must be removed. In order to accomplish this, wiring within terminal box must be disconnected.

2. Replacement must be positioned on the shaft so that bearing inner ring is against the bearing shoulder on the shaft.

3. Bearings should be removed with a puller that applies pressure to the bearing inner ring.

4. Bearings are a press fit on the shaft. Replacement bearing should be heated to +220° to +250° F. in a clean, temperature controlled oven before attempting to install them on the alternator shaft.

5. A replacement bearing should be installed on the shaft while it is hot as described above. A sleeve or pipe that applies pressure to the bearing inner ring may be used to tap the bearing into place on the shaft. The sleeve or pipe should never exert pressure on the bearing outer ring.

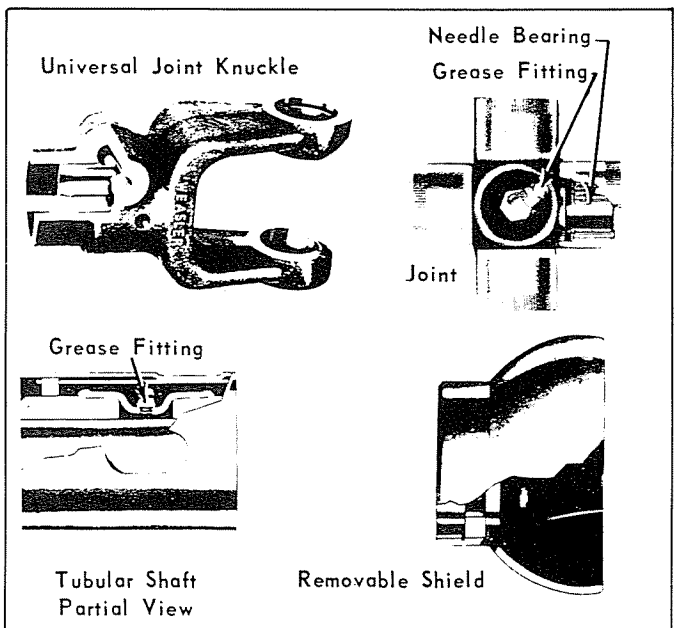


FIGURE 8 POWER TAKE-OFF SHAFT MAJOR PARTS

ALTERNATOR DISASSEMBLY AND ASSEMBLY

Disassembly of alternator can be accomplished by following these steps.

1. Refer to cutaway drawing for location of parts.

2. Remove bolts securing gear cases to alternator. Carefully remove gear case from shaft. A jaw type puller may be required on older units.

3. Disconnect leads within alternator terminal box. Remove bolts holding terminal box to alternator.

4. Remove bolts holding endbells to alternator frame and stator assembly. Pull endbells.

5. Remove exciter armature by disconnecting leads. (Carefully cut ties holding leads to exciter armature windings).

6. Generator rotor can be removed from fan end without removing fan.

7. Do not remove exciter field from endbell unless it is to be replaced.

8. Do not remove bearings if they do not require replacement.

Assembly of the alternator can be accomplished by following these steps:

1. If new bearings are to be installed refer to preceeding paragraphs titled Replacing Bearings.

2. If exciter field assembly was removed from end bell, install exciter field with lead wires toward endbell.

3. Slide alternator rotor into stator assembly.

4. Install endbells.

5. Install terminal box and reconnect wires. Refer to electrical diagrams contained in the Installation Section of this manual.

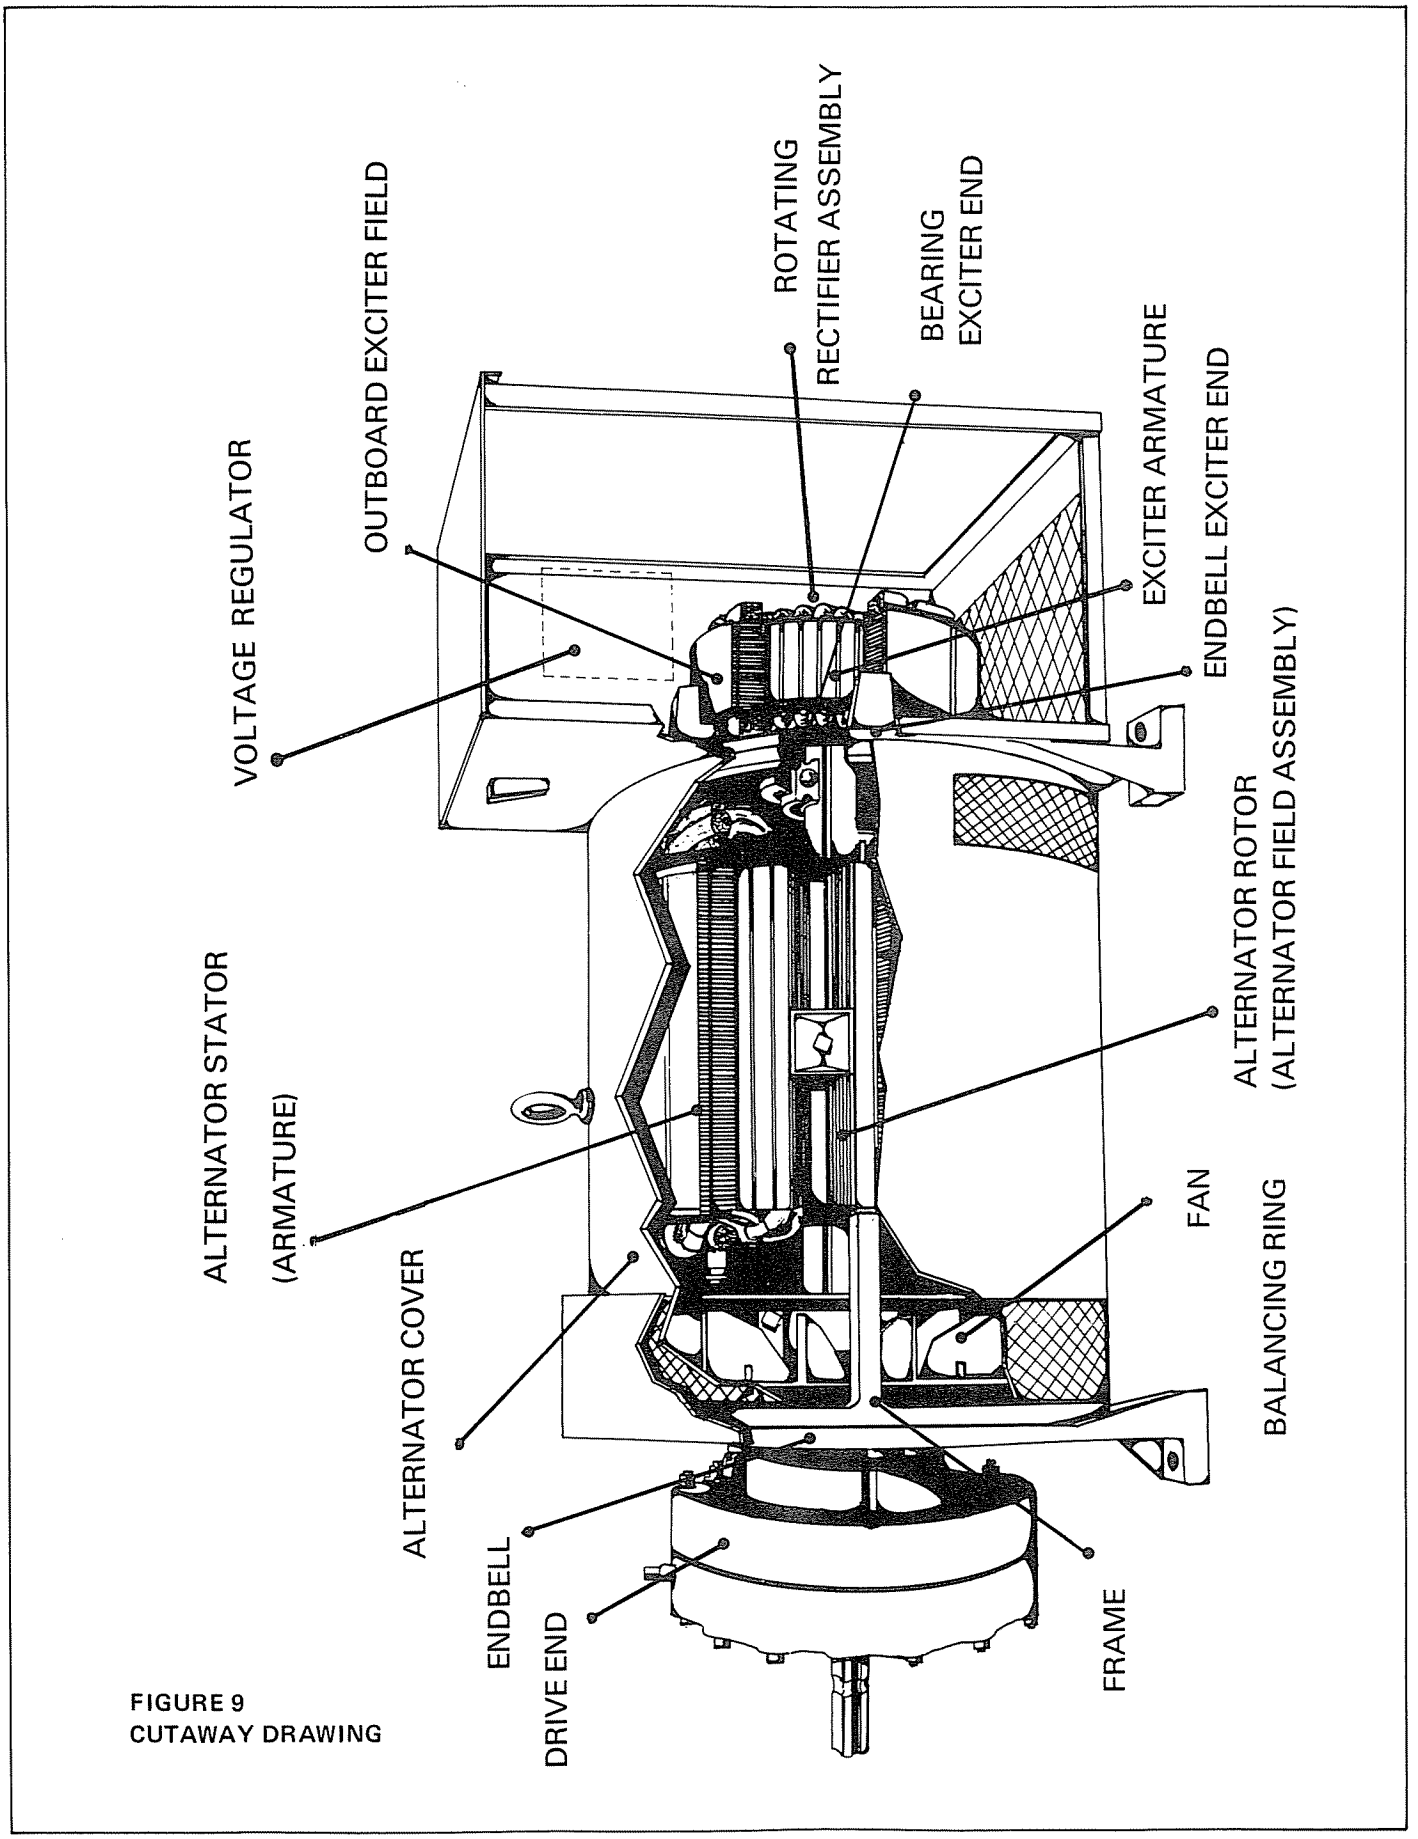

FIGURE 9
CUTAWAY DRAWING

LOCATING TROUBLE

If the alternator does not appear to be producing voltage, check the load circuit breakers or fuses. If a circuit breaker is tripped, reduce the load and reset the breaker. If fuses are blown, replace the fuses. A common cause of poor alternator operation is underspeed. High voltage can be caused by overspeed. Speed can be easily checked with a frequency meter or tachometer.

The following Troubleshooting Chart lists various symptoms of poor alternator operation, possible causes and means of correcting deficiencies.

TABLE D
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
No Output Voltage.	Engine Speed too low.	Increase speed until alternator produces 60 cycles.
	Short Circuit in load.	Disconnect load. Check motors, appliances and load leads for short circuit.
	Open fuse on voltage regulator.	Check section of foil on back side of voltage regulator marked "FUSE". If burned open install one piece of no. 34 wire across the burned open section of foil. Solder wire to foil, use care not to overheat when soldering.
	Defective receptacles.	Remove terminal box cover and test with test light.
	Loose terminal connections or shorted lead wires in control box.	Remove terminal box cover. Check terminal connections. Check for bare wires.
	Open fuses or circuit breakers.	Replace fuses. Reset circuit breakers.
	Voltage regulator defective.	Contact KATOLIGHT CORPORATION Sales and Service Office—Mankato, MN.
	Open or short circuited leads.	Remove alternator cover and check exciter field leads. Check leads from exciter armature to rotating rectifiers and alternator field coils. Make certain the tie down lacing holding exciter leads to shaft is securely wrapped and tied before placing unit back in operation.
	Open or shorted voltage adjust rheostat.	Check rheostat.
	Open or short circuited exciter field coils exciter armature windings, alternator field coils or alternator stator windings.	Consult KATOLIGHT CORPORATION Sales and Service Office—Mankato, MN.

CONTINUED

TABLE D
TROUBLESHOOTING CHART CONTINUED

SYMPTOM	POSSIBLE CAUSE	POSSIBLE REMEDY
Low Voltage	Engine speed too low.	Increase engine speed until alternator produces 60 cycle output.
	Voltage adjust rheostat not properly adjusted.	Adjust to rating.
	Alternator Overloaded.	Reduce load to rated value. Make certain alternator is not overloaded by unbalanced load.
	Short circuit in load.	Remove load. Check appliances and motors for point of short circuit.
	Defective voltage regulator or rotating rectifiers.	Consult KATOLIGHT CORPORATION Sales and Service Office –Mankato MN if voltage regulator is defective. Test rotating rectifiers.
High Voltage	Engine speed too high.	Decrease engine speed until alternator produces a 60 cycle output.
	Voltage adjust rheostat not set correctly.	Adjust to proper voltage.
	Defective voltage regulator.	Contact KATOLIGHT CORPORATION Sales and Service Office–Mankato MN.
Poor Voltage Regulation	Load in excess of alternator rating	Reduce load. Check nameplate rating.
	Wrong alternator speed or defective regulator.	Correct speed. Replace Regulator.
Continuous Voltage fluctuation	Engine speed not constant	Engine may not have enough power or engine governot may be worn or improperly adjusted. Set or repair defective governor.
	Defective Regulator.	Replace Regulator.
Vibration & Noise	Defective bearings	Replace bearings
	Gearbox dry or overfilled.	Check gearbox oil level.
	Power take-off misalignment excessive or universal joint dry or worn.	Correct defects. Refer to Operation section of this manual for alignment procedures.
	Loose mounting bolts	Check or tighten as necessary

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order:

1. Always give SERIAL NUMBER, and MODEL NUMBER.
2. Give the item part number and description. Give the quantity required of each item. DO NOT ORDER BY REFERENCE NUMBER OR GROUP NUMBER. If an old part cannot be identified return the part POSTAGE PREPAID to your distributor or KATOLIGHT CORPORATION. Write a letter to the same address stating the reason for returning the part.

Five Year P.T.O. Driven Alternator Limited Warranty

KATOLIGHT warrants to the original purchaser that the product delivered herewith, so far as it has been manufactured, engineered or assembled by KATOLIGHT, is free from defects in material and workmanship, and will perform under normal standby use and service for a period of five years from date of shipment from KATOLIGHT.

KATOLIGHT liability under the warranty specified herein shall be limited to the replacement or repair of the product, at the option of KATOLIGHT, or its authorized service station. This warranty does not apply to accessories supplied, but not manufactured by KATOLIGHT, which in such cases, the original equipment manufacturer's warranty will be applicable. This warranty does not obligate KATOLIGHT to bear the cost of labor or transportation charges in connection with the repair or replacement of defective products, nor shall it apply to a product upon which modifications, repairs or alterations have been made. This warranty shall apply only when the equipment or product has been properly installed, serviced and operated under normal standby conditions, in accordance with the instructions provided for the specific units.

KATOLIGHT shall not be liable for any claim greater in amount than the purchase price of the product, in respect of which such claim is made, and in no event shall KATOLIGHT be liable for any special, indirect or consequential damages.

THERE ARE NO EXPRESS WARRANTIES OTHER THAN THOSE DESCRIBED HEREIN. NO WARRANTIES SHALL BE IMPLIED OR OTHERWISE CREATED UNDER THE UNIFORM COMMERCIAL CODE, INCLUDING, BUT NOT LIMITED TO, A WARRANTY OF MERCHANTABILITY, AND A WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE.

ALTERNATOR DATA

The alternators described in this manual are single phase, 120/240 volt, 60 cycle, 1800 RPM machines. They are of the revolving field type with a static exciter voltage regulator. The alternator includes a line current operated excitation boost circuit which increases excitation proportional to increases in load. This feature provides excellent motor starting capabilities and provides sufficient current to trip breakers should a sustained short in the load or customers service lines occur.

Standard equipment includes the alternator and exciter/voltage regulator, a gear increaser, protective shield, an output circuit breaker, a fused 120 volt duplex receptacle, a 240 volt receptacle and a voltmeter.

Important data pertinent to your alternator is given on the nameplate attached to the alternator. For handy reference, copy the information from the alternator nameplate into the sample nameplate above. See Page 5 for "Operation Instructions".

GENERAL INFORMATION

INTRODUCTION

Before any Katolight Power Take-Off Driven Alternator is shipped from the factory, it is inspected and tested for performance. No unit is shipped unless it produces its rated capacity. When unpacking the machine, inspect it carefully making certain no damage occurred in transit. If damage is noted, notify the transportation company immediately, giving complete details as to the nature of the damage. Units are generally shipped with lubrication in the gearbox. Before placing power system in operation, check to make sure that the lubrication is in gearbox. IF NOT, fill VonRuden gearbox with 1¼ pints (1¼ lbs.) EP90 gear oil. Fill "Apex" gearbox with 2½ pints (2¼ lbs.) EP90 gear oil. Maintain oil level slightly below check plug.

If upon installation a new alternator does not work properly, check all electrical connections and the alternator speed before concluding the alternator is defective. Check name-plate for correct operating speed. Observe the following precautions whenever operating your Power Take-Off Driven Alternator.

CAUTION

DISENGAGE PTO WHENEVER TRACTOR IS IDLING. RUNNING ALTERNATOR UNDER SPEED COULD RESULT IN DAMAGE TO VOLTAGE REGULATOR AND ALTERNATOR.

PROVIDE SUFFICIENT VENTILATION. DO NOT OPERATE TRACTOR IN ENCLOSED AREA. EXHAUST GASES CONTAIN CARBON MONOXIDE, AN ODER—LESS, DEADLY POISON.

STOP TRACTOR BEFORE FILLING WITH GASOLINE. AVOID SPILLING GAS ON HOT ENGINE, A FIRE AND SERIOUS INJURY COULD OCCUR.

IN APPLICATIONS WHERE ALTERNATOR IS CON—NECTED TO SERVICE NORMALLY SUPPLIED BY COMMERCIAL POWER, INSTALL A TRANSFER SWITCH. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN ELECTROCUTION OF PERSONNEL SERVICING COMMERCIAL POWER LINES.

AVOID EXPOSURE TO ALTERNATOR VOLTAGE. WHENEVER MAKING ELECTRICAL CONNECTIONS OR REPAIRING THE ALTERNATOR, FIRST STOP THE TRACTOR. FAILURE TO OBSERVE THIS PRECAUTION COULD RESULT IN ELECTROCUTION.

PARTS ORDERING INSTRUCTIONS

To avoid errors or delay in filling your parts order, please furnish the following information:

1. Always give MODEL NUMBER, TYPE NUMBER and SERIAL NUMBER.

2. If an old part cannot be identified, return the part postage prepaid to your distributor or KATOLIGHT CORPORATION. Write a letter to the same address stating the reason for returning the part.

LOCATION

Provide sufficient ventilation. Do not operate tractor driven alternator in an enclosed area.

For best service the following factors should be taken into consideration:

1. Dirt: Foreign material such as dust, lint and abrasive particles cause excessive wear of bearings, brushes, and sliprings. Dirt also will clog ventilating ports causing overheating of the alternator.

2. Moisture: All electrical equipment should be protected from excessive moisture. Excessive moisture could result in short circuits and grounds.

If the alternator is to be left in the open, it should be covered whenever it is not in use. Ventilating ports should be cleaned periodically.

PERIODIC OPERATION AND INSPECTION OF STANDBY ALTERNATORS

Alternator should be operated and inspected occasionally to keep them in good operating condition.

About once every four months start the unit and bring up to rated speed. Apply load and check voltmeter reading. Run unit about ½ hour with some load applied. See "Operation Instructions".

At least once a year remove alternator cover and outlet box cover. Clean inside of alternator and outlet box with 25 to 50 psi compressed air. Check all wire connections, Check for broken wires and frayed insulation.

At least once a year check condition of brushes and sliprings. Clean if dirty. Replace brushes if worn excessively. Refer to Page 4, "Maintenance of Brushes and Sliprings".

DETERMINING THE LOAD

The load can be determined by adding the wattage requirements for each light, appliance and motor that will be operated by the power system. The following chart lists approximate watts required for various electrical appliances.

APPROXIMATE WATTS REQUIRED FOR ELECTRICAL APPLIANCES

APPLIANCE	WATTS
Lamp Bulbs	See Wattage on bulbs
Radio	40 - 200
Television	150 - 300
Vacuum Cleaner	200 - 250
Automatic Washer	400
Air Conditioner (¾ Ton)	1,250
Refrigerator	325
Food Freezer	300
Furnace (Oil)	700
Deep Well Pump	2,000
Electric Range	600 - 10,000
Hot Plate (per burner)	600 - 1,200
Toaster	600 - 1,130
Water Heater	1,500 - 5,000
Glow Heater	600 - 1,200
Heating Pad	40 - 80
Sun Lamp	250 - 1,000
Flat Iron	600 - 1,200
Laundry Dryer	4,750
Electric Heat System	5,000 - 20,000

USE OF ELECTRIC MOTORS

Electric motors require much more current to start than to run. Most fractional horsepower motors take about the same amount of current to run them whether they are of the Repulsion-Induction, Capacitor or Split-Phase type. Starting current however, varies greatly. Replusion-Induction motors are the easiest to start and usually require 1½ to 2½ times as much current to start as to run them. Capacitor motors usually require 2 to 4 times as much current to start them as to run them. Split-Phase motors are hardest to start with starting current about 5 to 7 times the running current.

NOTE

IN APPLICATIONS WHERE SEVERAL MOTORS ARE TO BE STARTED EXCESSIVE OVERLOAD MAY BE AVOIDED BY STARTING THEM ONE AT A TIME, STARTING THE MOTOR THAT REQUIRES HIGHEST RUNNING AND STARTING CURRENT FIRST.

RUNNING LOAD					STARTING
HP	KW	KVA	AMPERES		INRUSH
			115 V.	230 V.	KVA
1/4	.29	.53	4.6	2.3	3.45
1/3	.45	.75	6.5	3.25	4.15
1/2	.60	.92	8.0	4.0	5.75
3/4	.86	1.32	11.5	5.75	7.0
1	1.05	2.1	18.0	9.0	11.5
1.5	1.57	2.1	18.0	9.0	11.5
2	2.05	2.55	22.2	11.1	15.0
3	3.1	3.7	32.0	16.0	20.7
5	4.6	5.1	43.0	21.5	31.0
7.5	7.0	7.8	68.0	34.0	46.0

DATA FOR SINGLE PHASE MOTORS TO NEMA STANDARDS

INSTALLATION

MOUNTING ALTERNATOR

The alternator must be solidly bolted to a foundation, platform, or bed of a trailer. All four feet on the alternator must contact the foundation or trailer bed. If space exists between a mounting foot and the foundation or trailer, first install shims to take up space and then install and tighten bolts.

GEARBOX LUBRICATION

Check oil level. If not full, fill with EP 90 Gear Oil. Maintain oil level slightly below check plug. **DO NOT OVERFILL.** Overfilling will cause heating and possible seal failure.

CONNECTING ALTERNATOR TO LOAD

Load can be taken from receptacles, a cord set or by connecting the alternator into an existing service.

Load taken from receptacles should not exceed receptacle rating and should never exceed alternator rating. The 120 volt duplex receptacle is rated 20 amperes while the 240 volt receptacle is rated 50 amperes.

When the alternator is connected into an existing service normally supplied by commercial power a transfer switch must be used.

All loads that are not taken from 240 volt and 120 volt receptacles must connect to output side of alternator circuit breaker (lines L1 & L2) and neutral line to ground stud shown on wiring diagram page 8.

OPERATING INSTRUCTIONS

PRECAUTIONS PRIOR TO INITIAL STARTING

Before starting the alternator for the first time the unit should be inspected as follows:

1. Check electrical connections to load. Refer to the electrical connection diagrams.

2. Remove cover surrounding alternator. Turn rotor manually and visually inspect for sufficient clearance between rotating and stationary parts.

3. Check gear box oil level.

ALIGNING ALTERNATOR WITH TRACTOR POWER TAKE-OFF

The double universal joint construction of the power take-off drive shaft allows for considerable angular misalignment between the gearbox and the tractor power take-off shaft. As shown in Figure 2 the angular misalignment of the universal joints if at all possible should not be more than 15 degrees. If the power take-off drive shaft is taken apart make certain the drive shaft universal joint knuckles are in time with one another as shown in Figure 3. If the drive shaft universal joint knuckles are not in time; chattering will occur which will cause a flicker in the electrical output. The same flicker will also occur if the angle of the drive shaft from the alternator to the tractor power take-off is more than 15 degrees. Make certain the power take-off shaft shields are installed before operating the unit.

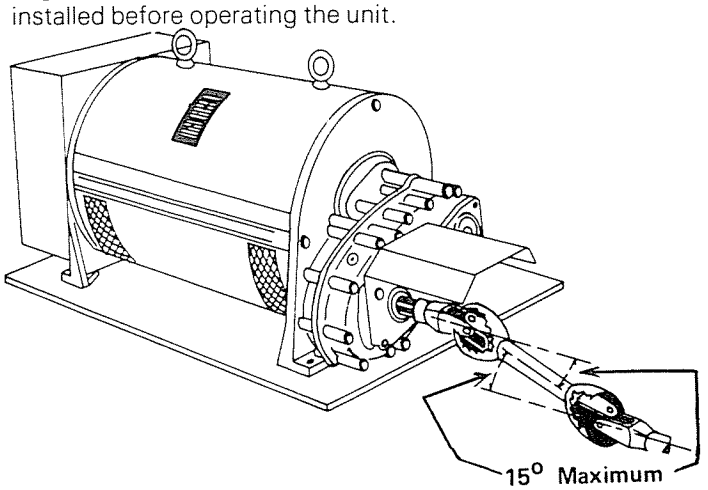

FIGURE 2 TRACTOR DRIVE ALTERNATOR CONNECTED TO TRACTOR POWER TAKE—OFF

OPERATING ALTERNATOR

1. With no load applied, start unit and bring tractor speed to point where the voltmeter needle is at 230 volts. (NOTE: if alternator does not appear to be generating voltage, then with unit running, flash field to restore residual magnetism as described on page 5.)

2. If alternator does not have frequency meter, then, with no load applied set throttle to point where the voltmeter reads 230 volts and observe tractor tachometer readings. The above tachometer reading is speed at which alternator frequency is about 60 cycles.

3. Apply load. Do not permit tractor speed to drop below alternator frequency of 60 cycles.

NOTE

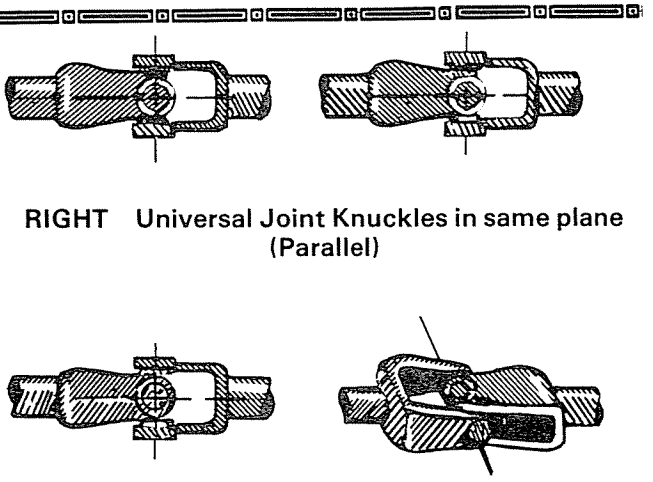
If alternator is supplying power to large motors, it may be advantageous to operate at speed slightly higher than 60 cycles but not over 63 cycles. 63 cycles would be a tachometer reading 5 percent higher than observed in Step 2.

CAUTION

DO NOT OPERATE OVER 63 CYCLES OR UNDER 60 CYCLES. DO NOT IDLE TRACTOR WITH PTO ENGAGED.

CONTROL ALTERNATOR FREQUENCY AND VOLTAGE BY KEEPING SPEED CONTROLLED (WITHIN ABOVE RANGE). DO NOT ATTEMPT TO CONTROL ALTERNATOR BY KEEPING VOLTAGE CONSTANT. IF VOLTAGE IS MORE THAN 264, MAKE CERTAIN SPEED IS NOT TOO HIGH. (OVER 63 CYCLES). (This is because speed controls frequency, while changes in voltage are caused by both changes in speed and changing load.)

IF VOLTAGE IS LESS THAN 216, MAKE CERTAIN THAT EITHER SPEED IS NOT TOO LOW OR ALTERNATOR IS NOT OVERLOADED.



RIGHT Universal Joint Knuckles in same plane (Parallel)

WRONG Universl Joint Knuckles NOT in same plane (NOT Parallel)

FIGURE 3 ALIGNING POWER TAKE-OFF SHAFT UNIVERSAL JOINTS FOLLOWING DISASSEMBLY AND REASSEMBLY OF POWER TAKE-OFF SHAFT

CLEANING

Do not permit ventilating ports to become clogged. Clean ventilating ports and inside of alternator using compressed air at a pressure of 25 to 50 PSI. Periodically clean brushes and sliprings. See "Periodic Operation and Inspection of Standby Alternators", page 1.

GEARBOX LUBRICATION

Periodically check level of oil in gear box. Maintain oil level slightly below check plug. Use EP 90 Gear Oil.

POWER TAKE-OFF SHAFT LUBRICATION

Periodically lubricate power take-off shaft. Location of grease points are shown in Figure 4.

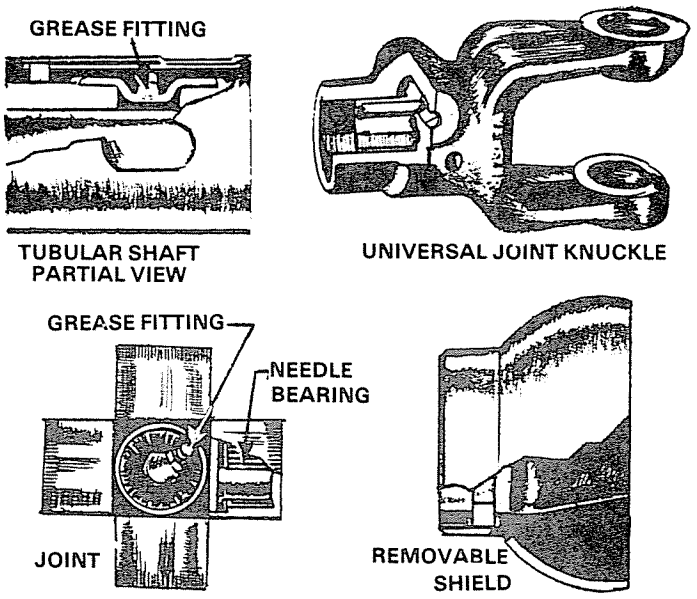


FIGURE 4 POWER TAKE-OFF SHAFT MAJOR PARTS

BEARING LUBRICATION

Bearings installed in the models listed above are of the shielded ball bearing type. They were factory packed about ½ full of a high quality ball bearing grease. Under normal operating conditions several years of operation can generally be expected before repacking of the bearings is necessary. However, it is difficult to predict bearing or grease life as each application is different. A noisy bearing can be a sign of either a worn bearing or lack of grease.

If bearings are to be repacked, remove shield from bearing and completely clean remaining lubricant from bearing and bearing housing. Carefully inspect bearing for any signs of wear. Repack bearing approximately ½ full using a high quality ball bearing grease. Grease should be capable of withstanding temperatures to +250 degrees F. Where use in cold weather is required, the grease should lubricate satisfactorily at the lowest ambient temperature.

REPLACING BEARINGS

Replacement bearings must be of the same size as originally installed at the factory. The following procedures must be followed:

1. If the rear bearing requires replacement, the terminal box and alternator endbell must be removed. In order to accomplish this, wiring within terminal box must be disconnected.

2. New bearing must be positioned on the shaft so that bearing inner ring is against the bearing shoulder on the shaft.

3. Bearing should be removed with a puller that applies pressure to the bearing inner ring.

4. Bearings are a press fit on the shaft. Replacement bearing should be heated to +220 to +250 degrees F. in a clean, temperature controlled oven before attempting to install them on the alternator shaft.

5. A replacement bearing should be installed on the shaft while it is hot as described above. A sleeve or pipe that applies pressure to the bearing inner ring may be used to tap the bearing into place on the shaft. The sleeve or pipe should never exert pressure on the bearing outer ring.

MAINTENANCE OF BRUSHES AND SLIPRINGS

Periodically, at least once or twice a year, loosen alternator wrapper cover and check condition of brushes and sliprings.

1. Never allow brushes to wear down to where brush spring is not holding brush against slipring. Check by lifting brush slightly and then releasing and observing spring pressing brush against slipring.
2. Check for cleanliness. Sliprings and brushes can be cleaned with a cloth. Small burn marks, pitts or grooves can be removed from sliprings as follows:

   a. Wrap fine sandpaper over wood block.

   b. Stop tractor. Remove alternator cover and outlet box cover.

   c. Make certain no load is applied to circuit breaker or receptacles.

   d. Lift brushes in their holders and lock in raised position with spring against side of brush.

   e. Disconnect F1 and F2 leads at (+) and (-) terminals on rectifier bridge BR1 which is located in alternator outlet box.

   f. Start tractor and bring up to about normal speed.

   g. Hold block with sandpaper cover against sliprings until they are polished.

   h. Stop tractor. Lower brushes. Connect F1 and F2 leads onto rectifier assembly BR1 (See Figure 7, Page 8). Install alternator covers.

RESTORING RESIDUAL MAGNETISM

If alternator will not produce voltage, it may be that the alternator has lost residual magnetism and needs to be flashed. Normally, flashing the alternator field using a 12 or 24 volt battery will restore residual magnetism. Flash as follows:

1. Remove outlet box cover and disconnect F1 & F2 leads at the (+) and (–) terminals on rectifier assembly BR1.
2. Connect lead from (+) terminal on 12 volt battery onto terminal on wire F2.
3. Start unit and bring up to speed but do not apply load.
4. Touch lead from (-) terminal of battery onto the terminal on wire F1. Leave on for a couple seconds and look at aternator voltmeter to see if voltage is building up. If voltage does not appear to be building up, it may be necessary to repeat flashing. If voltage still does not build up, flash with 24 volts by connecting two 12 volt batteries in series as shown in Figure 5.
5. Disconnect battery and reconnect F1 & F2 leads onto (+) and (-) terminals on rectifier BR1. See Figure 7, page 8, for propoer connection.

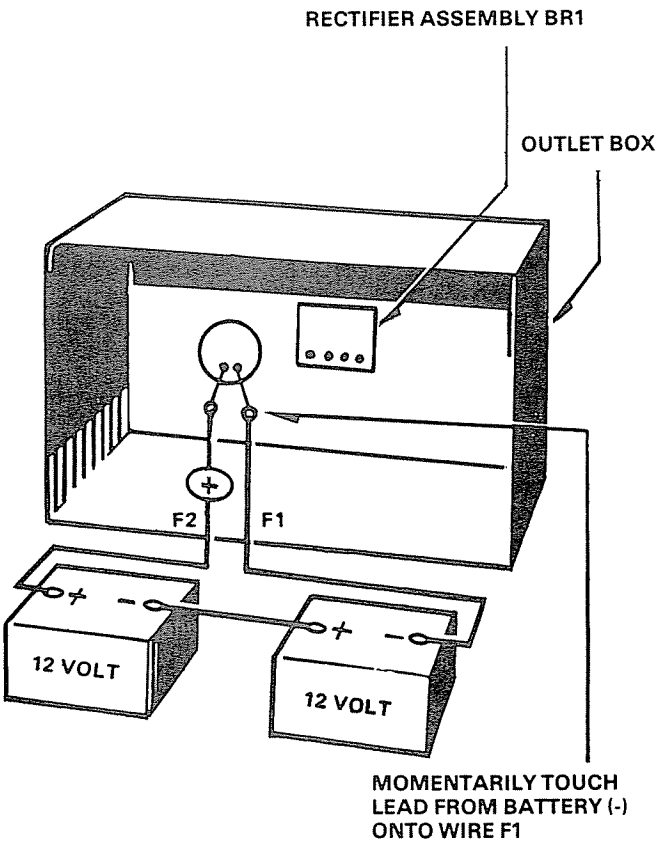

FIGURE 5 FLASHING FIELD USING 24 VOLTS (TWO 12 VOLT BATTERIES IN SERIES)

TESTING RECTIFIER ASSEMBLY BR1

This assembly consists of four diodes and a surge protector which can be tested for open or short circuits with a three volt test light as follows:

1. Stop tractor. Remove outlet box cover and disconnect wires from the two AC terminals and the (+) and (–) te rminals on the rectifier assembly.
2. Touch ends of tester leads together to make certain bulb lights.
3. Test surge protector by checking across AC terminals. Check with (+) lead on one AC terminal and (–) lead on other terminal. Interchange leads to AC terminals. Tester bulb should not light either way.
4. Check diodes as follows: Check with tester leads onto an AC and (+) terminal. Reverse leads from same AC terminal to (+). Light should come on in one direction but should not light when leads are reversed.
5. Repeat Step 4 but with lead from other AC terminal to (+).
6. Check with tester leads onto an AC terminal to (-). Reverse leads across same AC terminal and (-). Light should come on with leads onto AC and (-) terminals in one direction but should not light when they are reversed.
7. Repeat Step 6 but with lead from other AC terminal to (-).

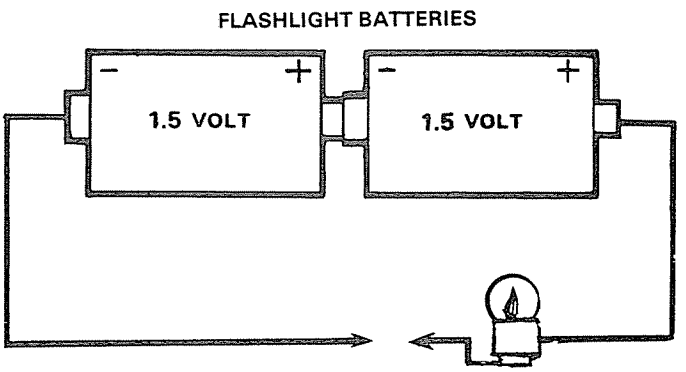

FIGURE 6 THREE VOLT TEST LIGHT

ALTERNATOR DISASSEMBLY AND ASSEMBLY

Disassembly of alternator can be accomplished as follows:

1. Refer to Figure 1, Page i, for part location.
2. Remove lifting eyebolt, alternator cover and outlet box cover.
3. Lift brushes in brush holders and lock them in raised position by placing brush spring against side of brush.
4. Remove bolts securing gear case to alternator. Carefully remove gear case from alternator shaft.

5. Disconnect leads within alternator outlet box. Remove bolts holding outlet box to generator.

6. Remove bolt and washer holding permanent magnet field assembly onto generator shaft. Remove permanent manget field assembly.

7. Remove bolts holding endbells to alternator frame and stator assembly. Pull endbells.

8. Alternator rotor can be removed from fan end without removing fan.

9. Do not remove bearings if they do not require replacement.

Assembly of the alternator can be accomplished as follows:

1. If new bearings are to be installed refer to preceeding paragraphs titled "Replacing Bearings".

2. Slide alternator rotor into stator assembly.

3. Install endbells.

4. Install outlet box. Install parts in outlet box and connect wires as shown on Figure 7, Page 8.

5. Slide permanent magnet field assembly onto alternator shaft. Install permanent magnet field retaining bolt and washer.

6. Lower brushes in brushholders.

7. Install alternator covers and lifting eyebolt.

8. Carefully install gear case.

TROUBLESHOOTING

LOCATING TROUBLE

If the alternator does not appear to be producing voltage, check the load circuit breakers or fuses. If a circuit breaker is tripped, reduce the load and reset the breaker. If fuses are blown, replace the fuses. A common cause of poor alternator operation is underspeed. High voltage can be caused by overspeed. Speed can be easlily checked with frequency meter or tachometer.

The following Troubleshooting Chart lists various symptoms of poor alternator operation as well as possible causes and means of correcting deficiencies.

TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSE	TEST PROCEDURE AND REMEDY
No Output Voltage	Engine speed too low.	Increase speed until alternator produces 60 cycles.
	Short Circuit in load.	Disconnect load. Check motors, appliances and load leads for cause of short circuit.
	Defective receptacles.	Remove terminal box cover & test with test light.
	Defective permanent magnetic field and / or stator.	Test PM armature (stator) for open or shorted windings. Test PM field for retention of magnetism. If magnetized,PM field should have high magnetic pull or a piece of steel such as a wrench or screwdriver. Replace failed parts.
	Loose terminal connections or shorted lead wires in control box.	Remove terminal box cover. Check terminal connections. Check for bare wires.
	Open fuses or circuit breakers.	Replace fuses. Reset circuit breakers.
	Rectifier Bridge BR1 open or shorted.	Test. Replace if open or shorted.
	Voltage regulator reactor LR1 or transformer CT1 open or shorted.	Consult KATOLIGHT CORPORATION Sales and Service Office - Mankato, Minnesota 56001.
	Short Circuit in load.	Disconnect load. Check motors, appliances and circuit wiring for cause of short circuit.
	Open or short circuited alternator field coils or stator windings.	Contact KATOLIGHT CORPORATION Sales and Service Office - Mankato, Minnesota 56001.

TROUBLESHOOTING CHART CON'T.

SYMPTOM	POSSIBLE CAUSE	TEST PROCEDURE AND REMEDY
Low Voltage	Engine speed too low.	Increase engine speed until alternator produces 60 cycle output.
	Unbalanced load or excessive length of lines or line size too small.	Balanced 120 volt loads evenly. If line drop is excessive reduce length of lines, increase line size to size per code for load amperage.
	Alternator overloaded.	Reduce load to rated value. Make certain alternator is not overloaded by unbalanced load.
	Short circuit in load.	Remove load. Check appliances and motors for point of short circuit.
	Defective rectifier assembly BR1 or transformer CT1 shorted.	Consult KATOLIGHT CORPORATION Sales and Service Office - Mankato, Minnesota 56001 if transformer is defective. Test rectifier assembly.
	Worn or dirty brushes or slipring.	Inspect. Clean with 00 sandpaper if dirty. Replace brushes if worn excessively.
High Voltage	Engine speed too high.	Decrease engine speed until alternator produces a 60 cycle output.
	Unbalanced 120 volt load.	Balance 120 volt loads evenly between L1 and N, L2 and N.
	Reactor LR1 shorted.	Contact KATOLIGHT CORPORATION Sales and Service Office - Mankato, Minnesota 56001.
Poor Voltage Regulation	Load in excess of alternator rating.	Reduce load.
	Low speed.	Increase to 60 cycles-per-second output frequency
	Unbalanced load.	Balance 120 volt loads evenly between L1 and N, L2 and N.
	Defective rectifier assembly BR1.	Test for open or shorts. Replace if defective.
Continuous Voltage Fluctuation	Engine speed not constant.	Engine may not have enough power or engine governor may be worn or improperly adjusted. Set or repair defective governor.
	Improperly connected gear box or PTO drive shaft.	Align PTO drive shaft. Check gearbox for loose mounting bolts and for excess backlash.
Vibration & Noise	Defective bearings.	Replace bearing
	Gearbox dry or overfilled	Check gearbox oil level.
	Power take-off mis-alignment excissive or universal joint dry or worn.	Correct defects. Refer to "Operation" section of this manual for alignment procedures.

N to L1 .0387Ω	G1 to L1 .25Ω	F1 to F2 field 9.86Ω	Field volts 80
L1 to L2 .0734Ω	G1 to G2 .25Ω	Reactor X1 to X2 .8Ω calculated	

Katolight Service - Master Repair Manual - Page 331

LIMITED Warranty

This alternator is warranted to produce its rated output as stamped on the nameplate when installed and operated in accordance with instructions.

It is warranted to be in good condition electrically and mechanically when leaving the factory.

It is warranted against electrical or mechanical defects in workmanship for a period of one year after shipment from the factory. Any parts found to be defective by factory inspectors after return to the factory, transportation charges prepaid, will be replaced or repaired free of charge. This does not include any component part or standard accessory such as meters, engines, relays, etc., made by other manufacturers, as these are subject to the warranties of those manufacturers.

IMPORTANT NOTICE

This manual includes information pertaining to installing, operating and servicing your generator.

READ THE INSTRUCTIONS CONTAINED IN THIS MANUAL AND FOLLOW THEM CAREFULLY WHEN INSTALLING AND OPERATING THE GENERATOR. THE ITEMS CONTAINED IN THE FOLLOWING CAUTION NOTE ARE ESPECIALLY IMPORTANT.

——— CAUTION ———

THE GENERATOR MUST BE RUN AT 1800 RPM GENERATOR SHAFT SPEED OR THE OUTPUT FREQUENCY WILL NOT BE 60 CPS. EITHER UNDERFREQUENCY (UNDERSPEED) OR OVERFREQUENCY (OVERSPEED) COULD RESULT IN POOR OPERATION OF MOTORS OPERATING FROM THE GENERATOR. PROCEDURES FOR CHECKING TO MAKE CERTAIN GENERATOR IS OPERATING AT 1800 RPM. 60 CPS ARE CONTAINED IN PARAGRAPHS 2.7, 2.8 AND 2.9.

ALTHOUGH SET AT THE FACTORY (115/230 VOLTS AT 60 CPS), THE FREQUENCY AND VOLTAGE SHOULD BE CHECKED DURING INITIAL OPERATION OF THE GENERATOR SET IN ORDER TO MAKE CERTAIN THE VOLTAGE ADJUST- RHEOSTATS AND VOLTAGE FREQUENCY INDICATOR LIGHT POTENTIOMETER HAS NOT BECOME OUT OF ADJUSTMENT DURING SHIPMENT. SEE PARAGRAPH 2.4. SHOULD ADJUSTMENT OF THE VOLTAGE ADJUST RHEOSTAT OR VOLTAGE - FREQUENCY INDICATOR LIGHT BE NECESSARY REFER TO PROCEDURES OUTLINED IN PARAGRAPHS 2.6 AND 2.7. IF THE VOLTAGE ADJUST RHEOSTATS AND VOLTAGE FREQUENCY INDICATOR LIGHT POTENTIOMETER REQUIRES ADJUSTMENT, LOOSEN LOCK-NUT BEFORE TURNING POTENTIOMETER OR RHEOSTAT SHAFT. RE-TIGHTEN LOCK-NUT AFTER MAKING ADJUSTMENTS TO PREVENT RHEOSTATS AND POTENTIOMETER FROM VIBRATING OUT OF ADJUSTMENT.

MAKE CERTAIN LOAD DOES NOT EXCEED RATING OF GENERATOR AND MAKE CERTAIN LOAD CONNECTED TO THE RECEPTACLES OR CORD SET DOES NOT EXCEED THEIR RATINGS. SEE PARAGRAPH 1.7.

MAKE CERTAIN THE POWER TAKE-OFF SHAFT UNIVERSAL JOINTS ARE ALIGNED WITHIN LIMITS. REFER TO PARAGRAPH 2.2. MAKE CERTAIN GEARBOX IS LUBRICATED. REFER TO PARAGRAPH 1.3.

ECTION I INSTALLATION

.1 INSPECTING GENERATOR BEFORE ACCEPTING HIPMENT

Carefully unpack the generator. Examine the generator heet metal cover and the terminal box for damage. Re- ove the terminal box cover and inspect for loose mount- ng bolts or screws and loose terminal connections. ighten any loose mounting bolts and terminal connections.

Remove the sheet metal cover which surrounds the enerator. Inspect the inside of the generator for signs f damage to windings, lead wires and other internal arts. Inspect to make certain that any foreign material uch as crating nails, loose bolts or packing material hich may have fallen into the machine during unpacking re removed.

When inspection determines that the generator was eceived in satisfactory condition, re-install the gener- tor cover and the generator terminal box cover.

.2 MOUNTING GENERATOR

Mount the generator on a foundation, platform or railer. The generator must be solidly bolted to the oundation or trailer. Install or remove shims as neces- ary until the generator sets evenly on the foundation r trailer bed at all four generator mounting points.

.3 GEARBOX LUBRICATION

Before operating the generator check the gearbox oil evel (NOTE: GEARBOX IS USUALLY SHIPPED DRY). Fill with 1½ pints (1½ pounds) EP 140 Gear Oil. Main- ain oil level slightly below filler plug. DO NOT OVER- FILL. Overfilling will cause heating and possibly seal failure.

1.4 GENERATOR BEARING LUBRICATION

The generator has shielded, factory lubricated, sealed cartridge type ball bearings. They require no further lubrication.

1.5 ELECTRICAL CONNECTIONS

Wiring diagrams, figures 1-1 and 1-2, show the elec- trical connections of Katolight TD-1 series generators. The load may be taken from any combination of the fol- lowing:

a. 115-120 volt duplex receptacle
b. 230 volt receptacle
c. 230 volt cord set
d. Separate lines run in as shown by dash (- - -) lines on drawings.

CAUTION

IF THE GENERATOR IS TO BE USED AS A STAND-BY POWER PLANT WIRED INTO EXISTING COMMERCIAL WIRING, A TRANSFER SWITCH MUST BE USED WHICH ISOLATES THE GENERATOR FROM THE COMMERCIAL POWER WHENEVER THE GENERATOR IS NOT OPERATED AND WHICH ISOLATES THE COMMERCIAL POWER LINES FROM THE GENERATOR WHEN THE GENERATOR IS USED.

1.6 DETERMINING THE LOAD

The maximum load which should ever be applied to the generator is the KW or wattage rating for the generator. This rating is stamped on the generator identification (data) plate. To aid in determining the load applied to the generator tables A and B list the average wattage of various appliances and motors. These tables should be used only as a guide, the actual load should be determined by adding the wattage of the appliances and motors from the identification data stamped on the appliances and motors.

1.7 OBTAINING LOAD FROM 115 AND 230 VOLT RECEPTACLES OR 230 VOLT CORD SET

When a 230 volt load is connected to either the 230 Volt receptacle or cord set the current of the load should not exceed 50 Amperes. Determine load current by adding the wattage rating of the 230 Volt appliances and the current rating of all motors which are to be connected to the load. To find the current of 230 Volt appliances from their wattage rating use the following formula:

$$\frac{\text{Wattage Rating}}{\text{230 Volts}} = \text{Current in Amperes}$$

Add the current rating of the motors and appliances. The total current rating should not exceed 50 Amperes; the rating of the receptacles and cord set.

Connection of a 115 Volt load to the 115 Volt duplex receptacle should be limited to 20 Amperes maximum. 115 Volt load current rating of 115 Volt appliances and motors should be determined as described above. The formula will change as follows:

$$\frac{\text{Wattage Rating}}{\text{115 Volts}} = \text{Current in Amperes}$$

When a load is applied at the same time to both the 115 Volt receptacle and the 230 Volt receptacle or cord set the following precautions should be observed:

a. Load current connected to 115 Volt receptacle should not exceed 20 Amperes. Load current connected to the 230 Volt receptacle or cord set should not exceed 50 Amperes.

b. Total current rating of the 230 Volt load added to the total current rating of the 115 Volt load should not exceed the Amperage rating of the generator indicated on the generator data plate.

1.8 STORING GENERATOR BETWEEN USE

Keep the generator in a building where it is protected from snow and rain and free of excessive dust.

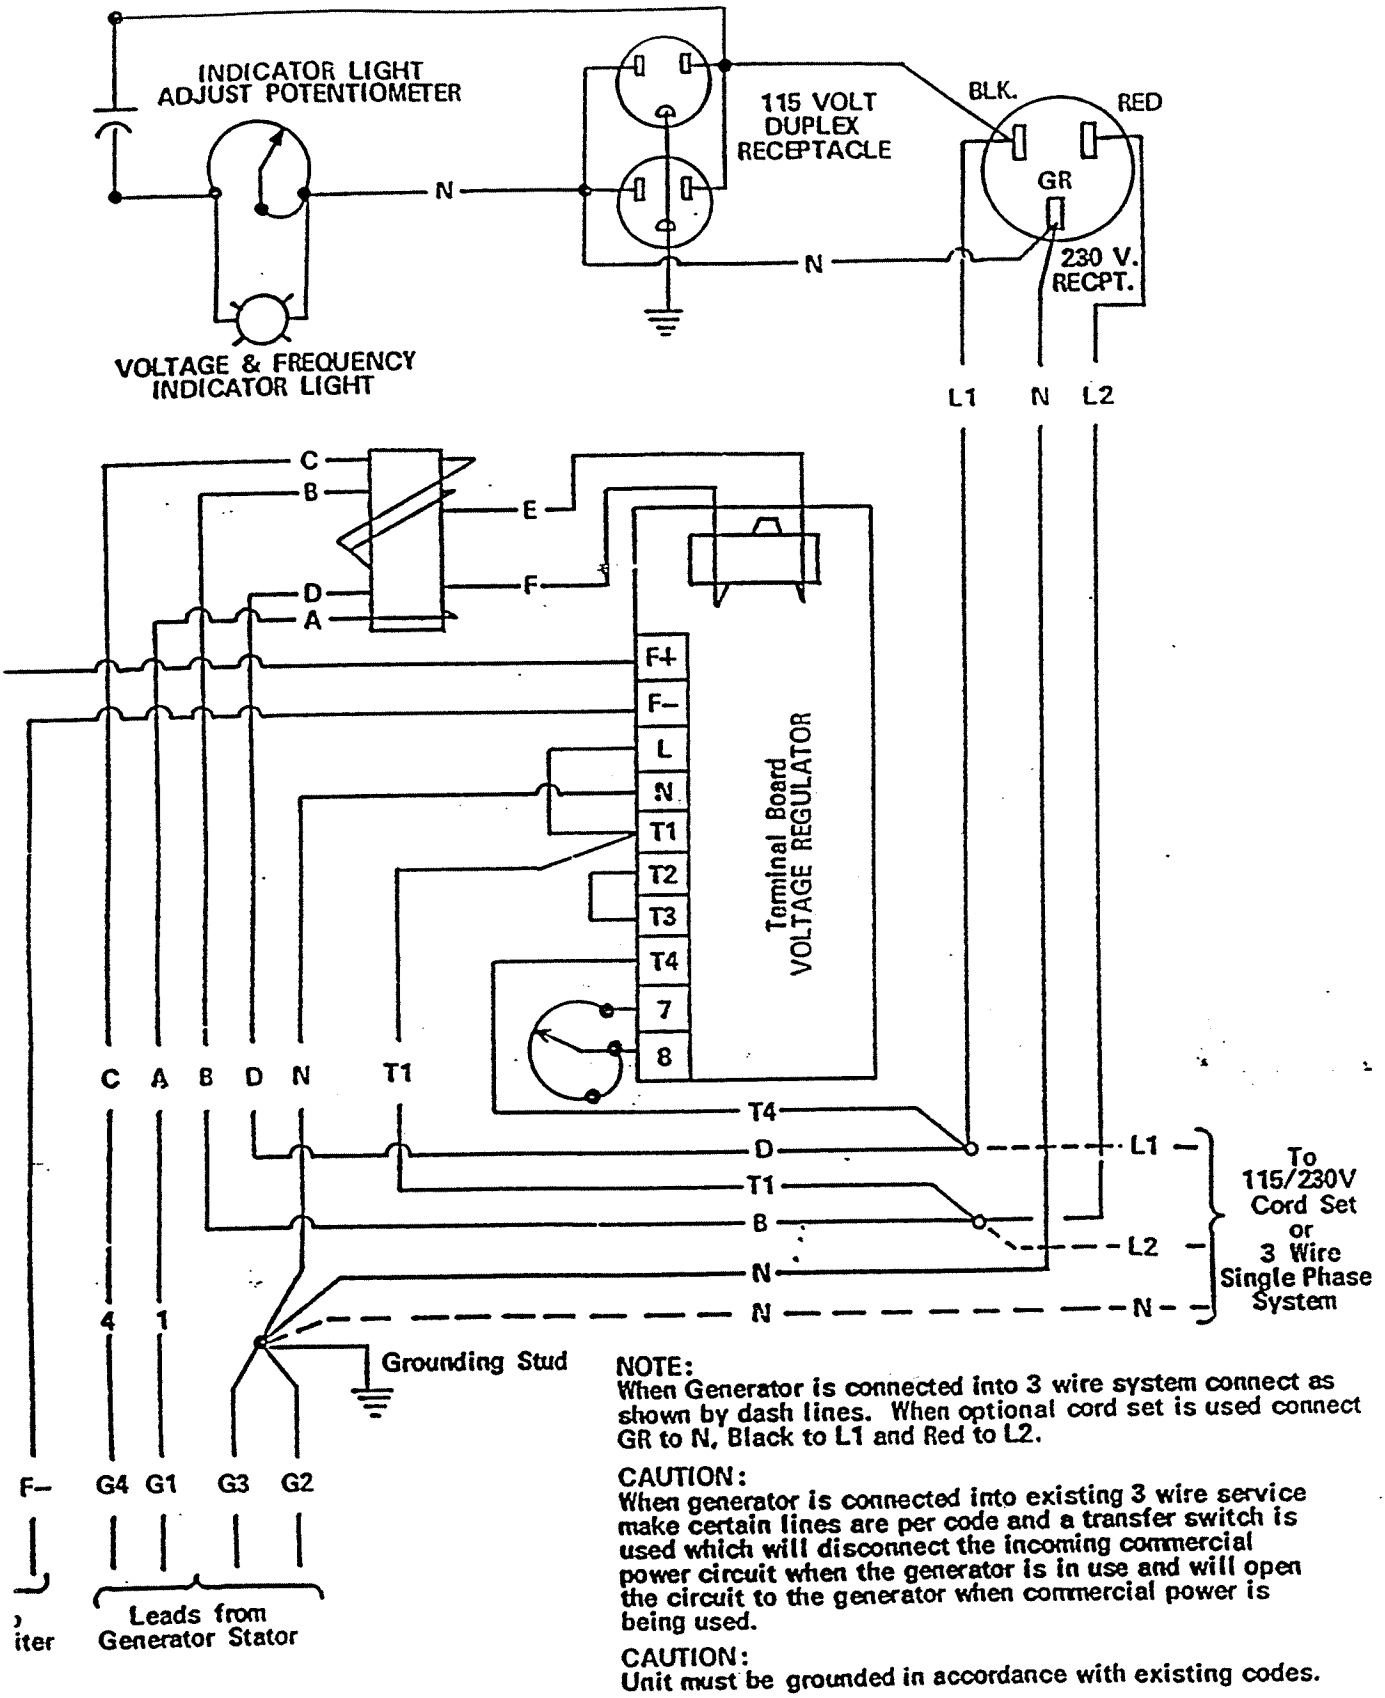
DATA FOR SINGLE-PHASE MOTORS TO NEMA STANDARDS

NOTE

Motor loads as seen by the generator include corrective factors for motor efficiency and power factor.

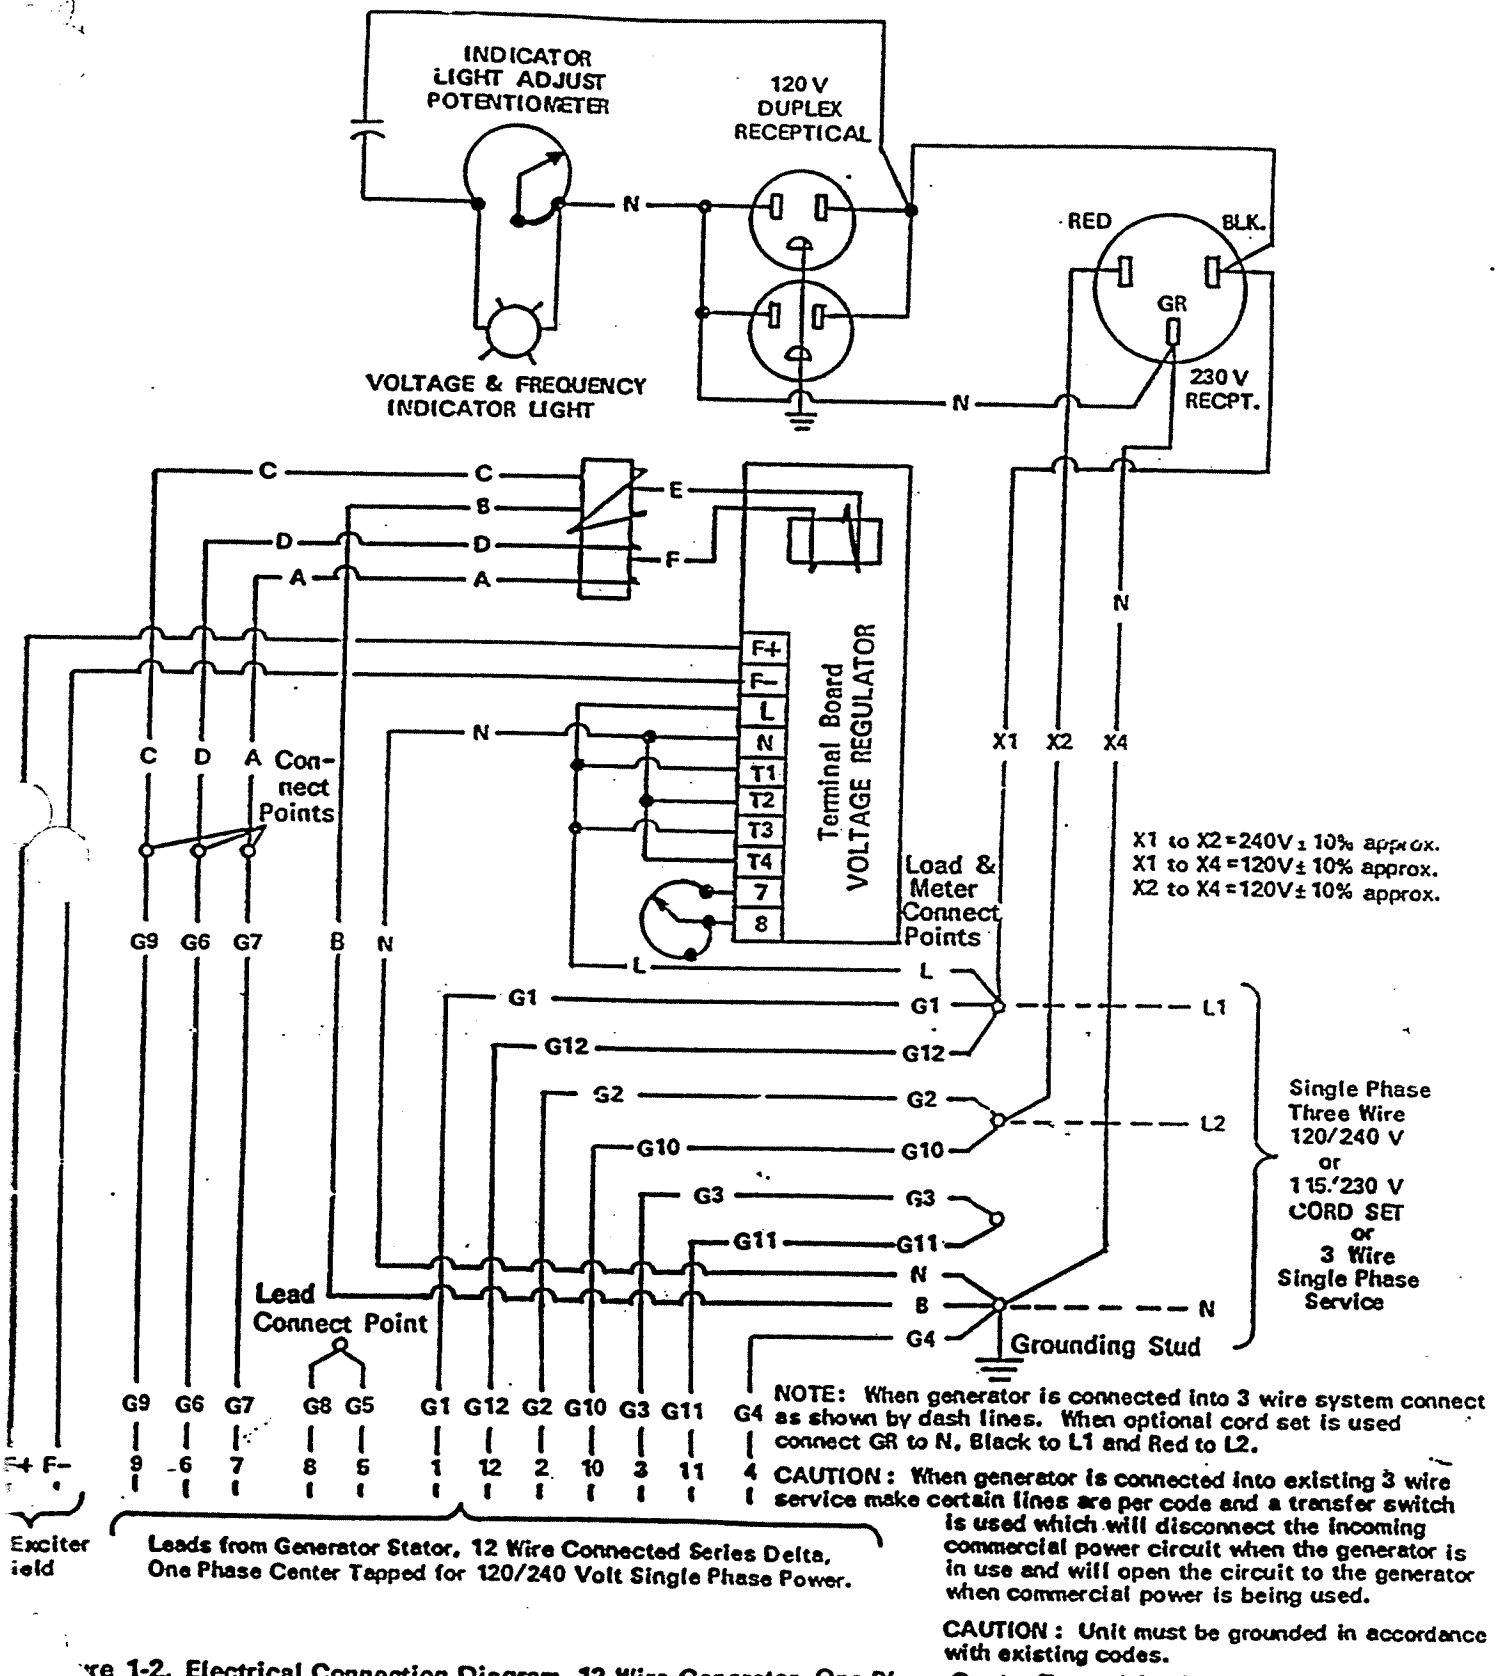


NOTE:
When Generator is connected into 3 wire system connect as shown by dash lines. When optional cord set is used connect GR to N, Black to L1 and Red to L2.

CAUTION:
When generator is connected into existing 3 wire service make certain lines are per code and a transfer switch is used which will disconnect the incoming commercial power circuit when the generator is in use and will open the circuit to the generator when commercial power is being used.

CAUTION:
Unit must be grounded in accordance with existing codes.

Figure 1-1. Electrical Connection Diagram, Single Phase, 4 Wire 120/240 Volt TD-1 Series AC Generator.



re 1-2, Electrical Connection Diagram, 12 Wire Generator, One Phase Center Tapped for Single Phase Power

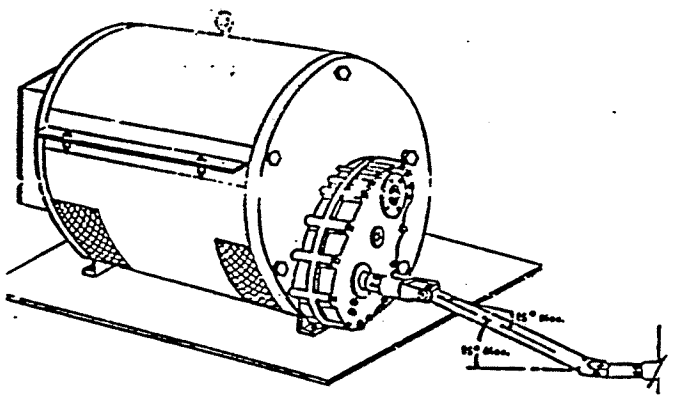
ECTION 2 OPERATION

.1 CONNECTING GENERATOR TO LOAD

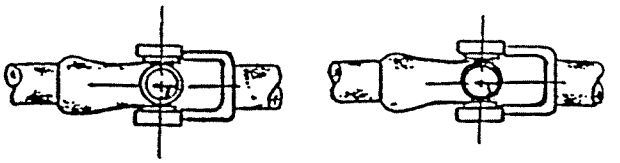
Make certain load connected to the 115 volt duplex receptacle, 230 volt receptacle or 230 volt cord set does ot exceed the rating of the receptacles or cord set. efer to paragraphs 1.5, 1.6 and 1.7

2 ALIGNING GENERATOR WITH TRACTOR OWER TAKE-OFF

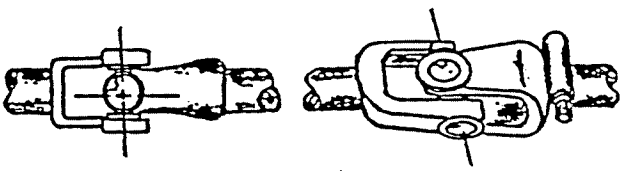
The double universal joint construction of the power ke-off drive shaft allows for considerable angular saligment between the gearbox and the tractor power ke-off shaft. As shown in figure 2-1, the angular isalignment of the universal joints if at all possible ould not be more than 15 degrees. If the power take- f drive shaft is taken apart make certain the drive aft universal joint knuckles are in time with one an- ner as shown in figure 2-2 when the power take-off aft is put back together. If the drive shaft universal int knuckles are not in time chattering will occur ich will cause a flicker in the electrical output. The me flicker will also occur if the angle of the drive aft from the generator to the tractor power take-off more than 15 degrees. Make certain the power take- shaft lock pin is properly engaged and the removable wer take-off shaft shields are installed before operat- g the unit.



gure 2-1 Tractor Drive Generator Connected To actor Power Take-off.



RIGHT Universal Joint Knuckles in same plane (Parallel)



WRONG Universal Joint Knuckles NOT in same plane (NOT Parallel)

Figure 2.2 Aligning Power Take-off Shaft Universal Joints Following Disassembly and Reassembly of the Power Take-off Shaft.

2.3 CHECKS TO BE MADE BEFORE STARTING GENERATOR

Before starting generator, make certain the following are satisfactory.

a. Make certain load connected to receptacles or cord set does not exceed their ratings. Make certain load is balanced. Refer to paragraphs 1.5, 1.6, 1.7 and 2.1.

b. Make certain power take-off is aligned satisfactorily and Gearbox is filled with grease. Refer to paragraphs 1.3 and 2.2.

c. When the generator is started in extremely cold weather, start the tractor and with the tractor idling, engage the power-take-off and let the clutch out slowly. Make certain the gearbox and generator rotor turns freely.

2.4 INITIAL START - GENERATOR USED FOR FIRST TIME

When the generator is used for the first time the following procedure should be followed:

a. Start the generator, bring up to rated speed of 1800 RPM (Generator shaft speed not engine speed). Refer to paragraphs 2.8 and 2.9.

b. Before applying load make certain output voltage is as required for load. Generator output voltage must be the same as the voltage rating of motors operating from generator. Procedures for adjusting voltage are listed in paragraph 2.6.

Katolight Service - Master Repair Manual - Page 340

c. Adjust combination Voltage and Frequency indicator light potentiometer as described in paragraph 2.7.

NOTE

e set as described in paragraph 2.7, the indicator ight will give a reasonably accurate indication that frequency is satisfactory. However, as a check we recommend either checking speed with a hand tachometer held on the generator shaft which extends through gearbox or check frequency with electric clock as described in paragraph 2.9.

d. When frequency and voltage have been adjusted the load can be applied. It may be necessary to readjust speed and voltage slighdy as engine speed may dip when load is applied.

5 NORMAL OPERATION

Before starting generator check unit as described in ragraph 2.3 steps a. through d.

Then start unit, bring up to rated speed and apply ad as follows.

a. Bring up to 1800 RPM generator shaft speed.

NOTE

set as described in paragraph 2.7, the indicator gh uld give a reasonably accurate indication that eed is correct. However, we recommend that as an ditional check either the speed should be checked th a hand tachometer held on the generator shaft which ends through the gearbox or that frequency is checked th an electric clock. See paragraphs 2.8 and 2.9.

b. Once set as described in paragraph 2.6, the voltage generally should not require further adjustment. If possible, it should be checked with an accurate voltmeter.

c. When it has been determined frequency is 60 CPS (1800 RPM) and that voltage is satisfactory load may be applied.

NOTE

ke certain load applied to receptacles and cord set es not exceed their ratings. Refer to paragraphs and 1.7.

NOTE

gine speed may dip slightly when load is applied and be necessary to increase engine throttle setting to return generator speed to 1800 RPM.

2.6 VOLTAGE ADJUSTMENT

When the generator is placed in operation for the first time. The voltage RANGE ADJUST rheostat and VOLTAGE ADJUST rheostat must be adjusted as described in the following steps (a) through (e). Once the RANGE ADJUST is set slight changes in voltage can be made by turning the VOLTAGE ADJUST rheostat.

a. Remove cover from terminal box. Refer to figure 2-3, page 7 for location of RANGE ADJUST and VOLTAGE ADJUST rheostats.

b. Set VOLTAGE ADJUST rheostat to midpoint position (half way between its full counterclockwise position). Turn RANGE ADJUST rheostat full-counter-clockwise (full resistance).

c. Start generator and bring up to 1800 RPM. Check speed with hand tachometer held on generator shaft which extends through gearbox.

d. Check voltage with an accurate voltmeter. Turn RANGE ADJUST rheostat to point where desired voltage is indicated on voltmeter.

e. The RANGE ADJUST rheostat should not require any further adjustment. Slight adjustments in voltage may be made by turning the VOLTAGE ADJUST rheostat.

2.7 COMBINATION VOLTAGE AND FREQUENCY INDICATOR LIGHT

When the generator is operated for the first time or should the voltage setting of the generator be changed, the potentiometer which controls the pick-up point of the indicator light must be adjusted.

Adjust indicator light potentiometer as follows:

a. Remove the terminal box cover. The indicator light potentiometer is mounted in the upper left hand corner of the terminal box. The potentiometer shaft is pointed to the back side of the terminal box so it will be necessary to turn its shaft by hand. DO NOT TOUCH WIRING.

b. Start generator and bring up to 1800 RPM, 60 CPS. Check speed with hand tachometer held on the generator shaft where it extends through the gearbox or check frequency with an electric clock as described in paragraph 2.8.

c. Make certain voltage has been correctly adjusted. Voltage should have been adjusted as described in paragraph 2.6 before the indicator light potentiometer is adjusted.

Katolight Service - Master Repair Manual - Page 341

d. When voltage is correct and you are sure generator is at 1800 RPM, 60 CPS, Turn the indicator light potentiometer until indicator light just comes on. If light was on, turn the potentiometer until the light goes off and then turn it back to point where light just comes on.

} CHECKING GENERATOR SPEED (FREQUENCY) TH HAND TACHOMETER

The generator output frequency will be 60 CPS when e generator shaft is turning at 1800 RPM.

An accurate hand tachometer held on the generator aft where it extends through the gearbox is a recommended method of checking to make certain the generator aft is turning at 1800 RPM.

NOTE

he generator has a frequency light which once set as escribed in paragraph 2.7 will give a reasonably accurate idication that the generator is operating at 1800 RPM. S AN ADDITIONAL CHECK RATHER THAN RELYG ON THE INDICATOR LIGHT WE RECOMMEND ITHER CHECKING SPEED WITH HAND TACHOMTER AS DESCRIBED ABOVE OR CHECKING FREUENCY WITH AN ELECTRIC CLOCK AS DESCRIBD IN PARAGRAPH 2.9.

.9 CHECKING GENERATOR FREQUENCY WITH .N ELECTRIC CLOCK

An electric clock plugged into the 115 volt duplex eceptacle provides a satisfactory means of checking requency. Check as follows.

a. Start generator and bring up to what you believe to be as close as possible to 1800 RPM (60 CPS). If the indicator light potentiometer has been adjusted, the indicator light can be used.

b. Plug an electric clock into the 115 volt duplex receptacle. Check the sweep of the second hand on the electric clock against the sweep of the second hand on a watch.

c. If the generator is at 1800 RPM (60 CPS) the second hand on the electric clock will move at the same speed as the second hand on the watch (through 60 seconds in 1 minute). If the generator is operating under speed the electric clock will slow down. If the generator is overspeed the electric clock second hand will move faster than normal.

d. Set engine throttle to point where second hand on the electric clock moves at the same speed as the second hand on watch.

2.10 VOLTAGE REGULATOR STABILITY ADJUST R8

STABILITY ADJUST resistor R8 is located on the printed circuit board. Only adjust STABILITY ADJUST R8 if during operation instability or slow response occurs. Turning STABILITY ADJUST clockwise increases negative feedback therefore, increasing stability and increasing response time. The STABILITY ADJUST should be set so that the output voltage of the generator is stable at both no-load and full-load allowing for the fastest regulator response.

NOTE

Make certain unit is at rated speed when making voltage and stability adjustments (60 CPS, 1800 RPM).

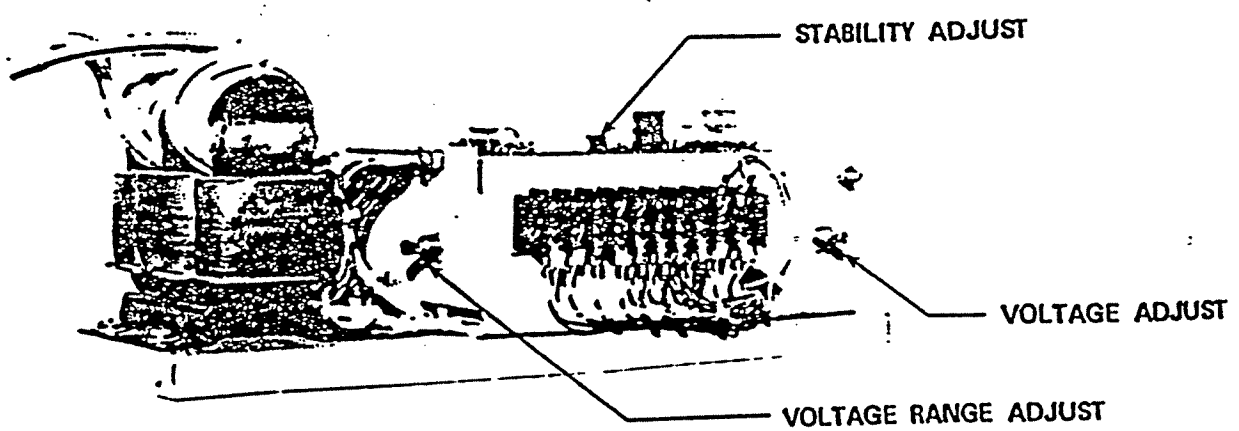


Figure 2-3 Voltage Regulator

Katolight Service - Master Repair Manual - Page 342

SECTION 3 SERVICE & MAINTENANCE

3.1 PREVENTIVE MAINTENANCE

Preventive maintenance is the practice of periodically inspecting the generator set, cleaning the generator set and eliminating any minor disorders before they become serious. A routine regular preventive maintenance program practiced conscientiously will insure peak performance, lengthen the life of the generator and greatly reduce the need for repairs. The 250 hour or Quarterly preventive maintenance schedule described in TABLE C is enclosed as a guide for establishing a preventive maintenance program for generators operating approximately 8 hours per day under normal conditions.

If the generator is not operated as many hours per Quarter the time between preventive maintenance inspection and service can normally be extended. If the generator is operated under severe conditions such as extreme dust, or blowing snow or rain the time between preventive maintenance inspections should be shortened.

3.2 CLEANING

When inspection determines cleaning is necessary clean the generator and controls as follows:

a. Remove dust from ventilating screens with a vacuum cleaner or use dry low pressure compressed air at 25 to 50 pounds.

b. Remove cover surrounding generator and blow dust from the inside of the generator with 25 to 50 psi compressed air or use a vacuum cleaner.

c. Remove terminal box cover. Blow dirt from controls with low pressure compressed air.

3.3 GEARBOX LUBRICATION

Lubricate gearbox with approximately 1½ pints (1½ lbs.) EP 140 Gear Oil. Maintain to slightly below filler plug. **DO NOT OVERFILL. OVERFILLING WILL CAUSE UNIT TO HEAT WHICH WILL CAUSE SEAL FAILURE.**

TABLE C

QUARTERLY OR 250 HOUR PREVENTIVE MAINTENANCE SCHEDULE

(4 TIMES PER YEAR)

1. Remove cover from generator. Inspect inside of generator for frayed lead wires, damaged windings and excessive dust. NOTE: Keep generator ventilating ports clean at all times. Check ventilating screens daily.

2. Remove terminal box cover. Inspect for frayed lead wires, loose terminal connections and excessive accumulation of dust.

3. Repair any frayed wiring. Tighten loose terminals. Clean generator and controls.

4. Check gearbox oil level.

5. Check power take-off drive shaft for dry universal joints. Grease if dry.

6. With unit running check for any unusual noise or vibration. Refer to trouble-shooting chart if there is any vibration or unusual noise.

7. With unit running check to make certain generator is operating at 1800 RPM, 60 CPS. Refer to Section 2 of this manual for procedures for checking speed.

8. With unit running check to make certain voltage is adjusted properly. Refer to the voltage adjustment procedure listed in Section 2 of this manual.

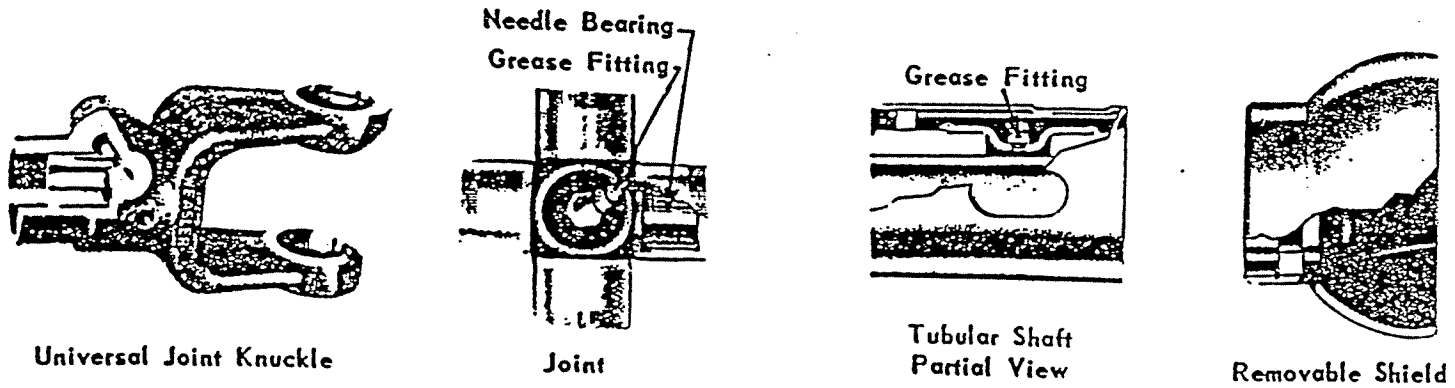

Figure 3-1 Power Take-off Shaft Major Parts.

Katolight Service - Master Repair Manual - Page 343

(POWER TAKE-OFF SHAFT LUBRICATION

As shown in figure 3-1, grease fittings are installed the universal joints and in the tubular shaft. Do not ergrease the universal joint needle bearings, but not allow the universal joints to become dry.

Periodic lubrication of the shaft splines will allow the aft to expand and compress easily as well as reduce ear.

.5 TESTING ROTATING RECTIFIERS

The rotating rectifiers are threaded into the generator haft. They can be tested with a continuity light constructed of two standard 1.5 volt flashlight batteries, a ulb and lead wires as shown in figure 3-2.

Test rotating rectifiers as follows:

a. With generator not running, remove the cover which surrounds the generator.

b. Unsolder the wire from the rotating rectifier.

NOTE

When removing lead wire or soldering lead wire back onto the rectifier make certain solder does not drop across rectifier terminal to the case as shown in figure 3.3. This would cause rectifier to become shorted. Use resin core solder - not acid core solder.

c. Remove the rectifier from the generator shaft.

d. Place tester leads across rectifier as shown by solid lines in figure 3-2. See if tester bulb lights.

e. Place tester leads across rectifier in the opposite direction as shown by dash lines on figure 3-2. See if tester bulb lights.

f. If the tester bulb lights in both steps d. and e. the rectifier is probably shorted and should be replaced.

g. If the tester bulb does not light in either steps d. or e. it is probably open circuited and should be replaced.

h. Replace any defective rectifiers. Solder lead wires back onto terminal of rectifier and then secure rectifier wires to shaft with tie-down lacing.

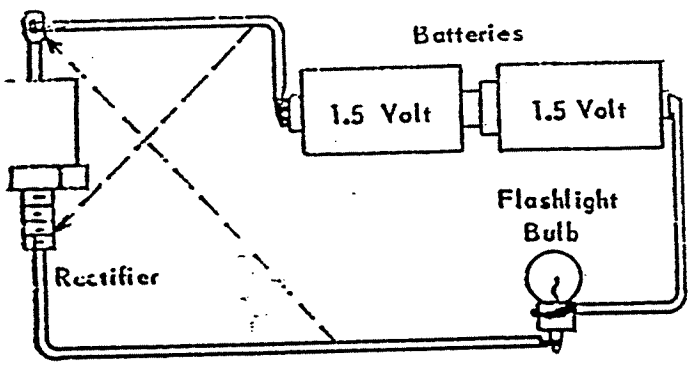

Figure 3-2 Testing Rectifiers with Test Lamp

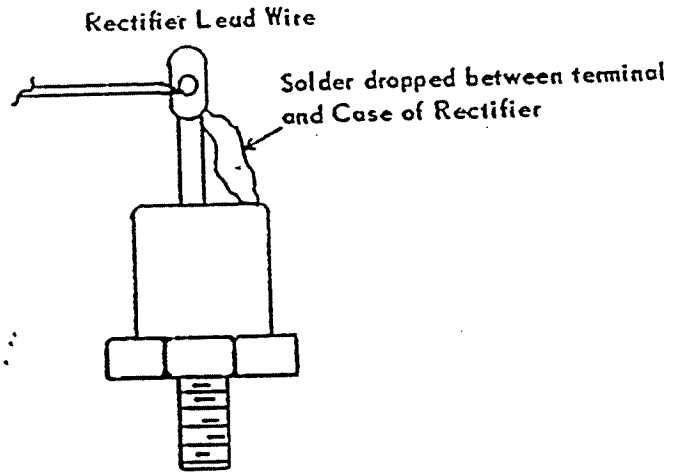

Figure 3-3 Rectifier Shorted Due to Solder Dropped Between Terminal and Case

TABLE D
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSE	REMEDY
No Output Voltage	Engine speed too low.	Increase speed until generator produces 60 cycle. See Section 2.
	Short circuit in load.	Disconnect load. Check motors, appliances and load leads for cause of short circuit.
	Defective receptacles	Remove terminal box cover & test with test light. Make certain 230 Volt receptacle is tested between the RED & GR and the BLACK & GR points. Replace defective receptacle.
	Loose terminal connections or shorted lead wires in control box.	Remove terminal box cover. Check terminal connections. Check for bare wires.
	Open fuses or transfer switch. When generator is connected directly to 3 wire, 115/230 volt system.	Replace fuses. Set transfer switch to correct position.
	Voltage regulator defective	Contact KATOLIGHT CORPORATION Sales and Service Office – Mankato, Minnesota.
	Open or short circuited leads.	Remove generator cover and check exciter field leads and leads from exciter armature to rotating rectifiers and generator field coils. Make certain the tie-down lacing holding exciter leads to shaft is securely wrapped and tied before placing unit back in operation.
	Open or short circuited voltage adjust rheostat or range adjust rheostat.	Check rheostats. Replace if defective.
	Open or short circuited exciter field coils, exciter armature windings, generator field coils or generator stator windings.	Consult KATOLIGHT CORPORATION Sales and Service Office – Mankato, Minnesota.
Low Voltage	Engine speed too low.	Increase engine speed until generator produces 60 cycle output. Refer to Section 2.
	Voltage adjust potentiometer not properly adjusted.	Adjust as described in Section 2.
	Generator Overloaded.	Reduce load to rated value. Make certain generator is not overloaded by unbalanced load. Refer to sections 1&2.
	Short circuit in load.	Remove load. Check appliances and motors for point of short circuit.
	Defective voltage regulator or rotating rectifiers.	Consult KATOLIGHT CORPORATION Sales and Service Office-Mankato, Minnesota if voltage regulator is defective. Test rotating rectifiers.

TROUBLESHOOTING CHART

(Continued)

SYMPTOM	POSSIBLE CAUSE	REMEDY
High Voltage	Engine speed too high	Decrease engine speed until generator produces a 60 cycle output. Refer to Section 2.
	Voltage adjust rheostat or range adjust rheostat not set correctly.	Set rheostats Refer to Section 2.
	Defective voltage regulator.	Contact KATOLIGHT CORPORATION Sales and Service Office – Mankato, Minnesota.
Poor Voltage Regulation	Load in excess of generator rating.	Reduce load. Refer to Sections 1 and 2.
Continuous Voltage Fluctuation	Engine speed not constant.	Engine may not have enough power or engine governor may be worn or improperly adjusted. Set or repair defective governor.
Vibration and Noise	Defective bearings.	Replace bearing. Consult KATOLIGHT CORPORATION before attempting to replace bearing.
	Gearbox dry or overfilled.	Check gearbox oil level.
	Power take-off mis-alignment excessive or universal joints dry or worn.	Correct defects. Refer to Section 2 for alignment procedures.

WARRANTY

This generator is warranted to produce its rated output as stamped on the nameplate when installed and operated in accordance with instructions.

It is warranted to be in good condition electrically and mechanically when leaving the factory.

It is warranted against electrical or mechanical defects in workmanship for a period of one year after shipment from the factory. Any parts found to be defective by factory inspectors after return to the factory, transportation charges prepaid, will be replaced or repaired free of charge. This does not include any component part or standard accessory such as meters, engines, relays, etc., made by other manufacturers, as these are subject to the warranties of those manufacturers.

SERVICE MANUAL FOR KATOLIGHT ELECTRIC GENERATORS

01/01/01

KATOLIGHT SERVICE MANUAL

WARNING: 1. This manual is only intended for Katolight Master Reps or Distributors.
2. Only Qualified Installers.
3. Before reading this manual please read all manuals accompanying unit.

INTRODUCTION

General Information

Read this manual carefully before operating or servicing generators to familiarize yourself with proper safety, operation and maintenance procedures. FAILURE TO COMPLY WITH INSTRUCTIONS IN THIS MANUAL COULD RESULT IN PERSONAL INJURY, PROPERTY DAMAGE AND/OR VOIDING OF THE WARRANTY. KATOLIGHT WILL NOT BE LIABLE FOR ANY DAMAGE BECAUSE OF FAILURE TO FOLLOW THESE INSTRUCTIONS.

Check the unit over for any signs of freight damage. Check item list; Transfer Switch, Literature, Battery hold down kit, Diode, and Insulated Connectors for AC and DC wires should all be included with unit.

This manual is not all inclusive. Each operating unit has a manual specific to its use.

Basic Generator Operations (Simplified)

Electric power is produced in the generators by a magnetic field rotating inside a stator. This is a brush less type generator. To start producing electricity, it is the residual magnetism in the rotor's metal core which induces a small amount of current in the stator. This current is fedback into the rotor (increasing the magnetic field and the amount of current induced) until the rotor's magnetic field reaches saturation. At this point there is sufficient energy present in the stators output windings to operate the unit at its rated capacity.

Usage

The generator is connected with the home electrical distribution panel(s), via the transfer switch. It is intended that this unit be used in the following manner.

When the normal electrical service is interrupted the automatic transfer switch (ATS) will signal the generator control circuit to start the engine. When the generator output voltage reaches a predetermined level, the ATS will automatically switch the load distribution panel to the generator output power. After utility service has been restored, the ATS switches the load back to the utility power and the generator shuts down after a short cool down period.

Once every 14 days the generator will "exercise itself". This means it will start and run for 20 minutes insuring that the unit is in a good operating condition when needed.

.

GENERATOR TERMINOLOGY

ALTERNATING CURRENT	Alternating current or AC is the flow of electrons in a conductor, first in one direction then in the other.
AMPERES (AMPS)	The rate of electron flow through a conductor is measured in amperes, which is a measurement of electrons flowing past a given point at a given time.
DIRECT CURRENT	Direct current or DC is the flow of electrons in only one direction through the conductor.
HERTZ	A unit of frequency equal to one cycle per second.
OHM	One Ohm is the amount of resistance that will permit one ampere of current to flow in a conductor when one volt of electro-motive force is applied.
ROTOR	The rotor is essentially an electro-magnet, since the flow of direct current through its windings creates a magnetic field around those windings. The strength of the magnetic field can be increased by (a) forming the wires into a coil, (b) increasing the wire size, or (c) increasing the current flow through the wires
SINE WAVE	A wave diagram (sine wave) of alternating current shows that current goes from a zero value to a maximum positive value, reversing itself again and returns to zero. Then it goes to a maximum negative value, reversing itself and returns to zero.
STATOR	The number of turns of wire in a stator winding are determined when it is manufactured. A typical stator assembly may be a single-phase type, or a 3 phase type. The greater the number of turns of wire in a stator winding, the greater the induced EMF when magnetic lines of flux cut through the windings.
VOLTS	The volt is the amount of electro-motive force (EMF) that will result in a current (electron) flow of one ampere through a resistance of one Ohm.
WATTS	One watt is equal to one ampere of current flow under pressure of one volt. Calculate electrical power by using the formula: WATTS = VOLTS x AMPERES.

INSTALLATION

Site Selection and Preparation

Location:

The unit should be placed in an area that allows plenty of room around the generator for ventilation and maintenance. Approximately 3 feet on each side. Covering or restricting the air passages on the sides of the generator unit will cause the unit to overheat. Examples would be landscaping, piles of leaves, or piles of snow. Leaving a three foot open area around the unit will help in preventing any overheating. When placing the generator, the direction of the exhaust should be pointing away from windows, doors, and any ventilation systems. **Do not install indoors.**

Pad;

Holes provided in the frame are .375" diameter but we recommend a 1/4" lag bolt to allow for variance of placement in the cement. The unit should be bolted on a cement pad that is 4 to 6" thick. The cement pad for the 9kW should be 42.25" wide and 50.75" long. The cement pad for the 15kW should be 48" wide and 72" long. The unit is mounted on rubber isolaters to the frame to make the unit run as vibration free as possible.

Fuel;

For the best operation of the Lighthouse unit the fuels used should have a minimum content of 1000 BTU's per cubic foot for Natural Gas (NG) and 2520 BTU's per cubic foot for Liquid Propane (LP). Contact local supplier for local BTU content. Line pressure for the 9kW and 15kW should be a maximum of 8oz. and a minimum of 4oz. When connecting fuel supply, installation of a manual shutoff valve at the unit is recommended.

The Lighthouse 9kW at full load consumes 162 cubic feet per hour or 162,000 BTU's per hour of Natural Gas (NG) and 72 cubic feet per hour or 182,000 BTU's per hour of Liquid Propane (LP). Approximately 2 gallons of Liquid Propane per hour at full load. The Lighthouse 15kW at full load consumes 285 cubic feet per hour or 285,000 BTU's per hour of Natural Gas (NG) and 122 cubic feet per hour or 308,000 BTU's per hour of Liquid Propane (LP). Approximately 3.1 gallons of Liquid Propane per hour at full load.

⚠ WARNING

- **FIRE HAZARD**
  Overheating of unit may cause fire and serious personal injury.
- Covering or restricting the air passages on the sides of the Lighthouse units will cause the unit to overheat and may create a fire hazard. Examples would be landscaping, leaves or piles of snow.
- Leaving a three foot open area around the unit will help in preventing any overheating.

⚠ WARNING

- **EXPLOSION HAZARD**
  Natural gas and Liquid Propane are highly explosive.
- Natural gas is lighter than air and will collect in high places. Liquid Propane vapor is heavier than air and will collect in lower places.
- Extreme caution should be taken when working on a new installation or while performing general maintenance.
- Do not smoke or use open flame during maintenance.

Lighthouse units are tested with Natural Gas before they leave the factory. If Natural Gas is to be used no carburetor adjustments are required. If Liquid Propane Gas is going to be used the carburetor solenoid will need to be connected, for the 9kW unit. Follow these steps to install the LP fuel orifice for LP Gas operation of the 15kW unit.

1. The main fuel line clamp will have to be loosened and the line removed from the carburetor.
2. Install the LP fuel orifice with a straight blade screwdriver. The fuel inlet to the carburetor is internally threaded to receive the LP orifice.
3. After the LP orifice is installed reattach the fuel line and retighten the clamp. The 15kW is now equipped to run off LP Gas.

The carburetor jets are factory set for LP Gas and no adjustments beyond orifice installation are necessary for LP Gas operation. Use only the vapor withdrawal type system if Liquid Propane Gas (LP) is to be used.

WARNING: The installation of this type of equipment must be done by licensed electrician's or contractors and licensed gas technician or plumbers. Installation must be in conformance with NEC and local electrical and building codes. Utility disconnect must be in the off position before you start any wiring. To insure safe installation of unit make sure Mode switch, on control box, is in the off position.

System Wiring

The installation of the Automatic Transfer Switch must be done by a qualified electrician. Under no circumstance should an unqualified person attempt to install this equipment. The instructions on the installation of the Automatic Transfer Switch are with the transfer switch and must be followed for correct installation and operation. Locate the transfer switch as close as possible to the distribution panel(s). The amperage rating of the transfer switch must be at least as large as the amperage rating of the distribution panel(s). A series 165, 100 amp ATS must be used with a distribution panel(s) up to 100 amps.

The recommended method to connect the Lighthouse system to the home desired circuits is through a Emergency Distribution Panel(s). This panel(s) must be sized to the generator amperage capability. Always follow the local codes and regulations. All selected emergency circuits are removed from main distribution panel(s) and reinstalled in the Emergency Distribution Panel(s). Total running load must not exceed generator rating or there will be a risk of overloading and damaging the generator.

Refer to the wiring diagrams contained in this manual for proper connection of the AC circuit. The two AC power leads must be connected directly to the main circuit breaker in the generator control box. The neutral wire must be connected to the neutral provided. A green ground wire from the ATS must also be connected to the ground connection in the control box. Ensure that all local codes are followed when making these connections. A ground lug is provided on the rear of enclosure to which a bare ground wire must be connected to a ground rod driven into the earth. A 120 volt circuit will need to be installed, inside the 240 volt conduit, from the utility to the control box of generator for the battery charger plug.

9kW UNIT

Refer to the wiring diagrams contained in this manual for proper connection of the DC circuit. The insulated quick connect terminals provided must be used to make these connections. A four wire cable (SJO16/4) is needed between the control panel and the transfer switch run through a different conduit from the AC leads. Remove ATS cover and locate the green connection block. Terminal Block (TB) positions 3,4,5,7 and 8 will be used. Connections at the generator are within the control panel at terminal strip positions 2,3,4, and 6. The insulated spades included must be used. Connections are:

ATS 3 connects to Generator position 6.
ATS 4 connects to Generator position 3.
ATS 7 connects to Generator position 4.
ATS 8 connects to Generator position 2.
ATS 5 connects to ATS 7 with provided diode. Diode cathode connects to position 5.

It is important that each wire be connected to the proper terminal, otherwise the system will not operate correctly.
Note page 6 for wiring diagram and preferred method of connection and installation of the DC circuit, transfer switch.

15kW UNIT

Refer to the wiring diagrams contained in this manual for proper connection of the DC circuit. The insulated quick connect terminals provided must be used to make these connections. A four wire cable (SJO16/4) is needed between the control panel and the transfer switch run through a different conduit from the AC leads. Remove ATS cover and locate the green connection block. Terminal Block (TB) positions 3,4,5,7 and 8 will be used. Connections at the generator are within the control panel at terminal strip positions 1,2,3, and 4. The insulated spades included must be used.
Connections are:
ATS 3 connects to Generator position 4.
ATS 4 connects to Generator position 3.
ATS 7 connects to Generator position 2.
ATS 8 connects to Generator position 1.
ATS 5 connects to ATS 7 with provided diode. Diode cathode connects to position 5.

It is important that each wire be connected to the proper terminal otherwise the system will not operate correctly.
Note page 32 wiring diagram for installation of the DC circuit.

⚠ WARNING

- **ACID BURN**
  Battery electrolyte fluids comprised of sulfuric acid that can be very dangerous and cause severe burns.
- Do not allow this fluid to contact eyes, skin, clothing, etc. If contact or spillage does occur, flush the area with water immediately.

⚠ WARNING

- **EXPLOSION HAZARD**
  Batteries contain sulfuric acid (when filled) and may emit explosive gasses.
- Read and follow safety instructions accompanying the battery.
- Keep sparks, flames and cigarettes away.
- Hydrogen gas is generated during charging and discharging.
- Always shield eyes, protect skin and clothing when working near batteries.

Battery Installation

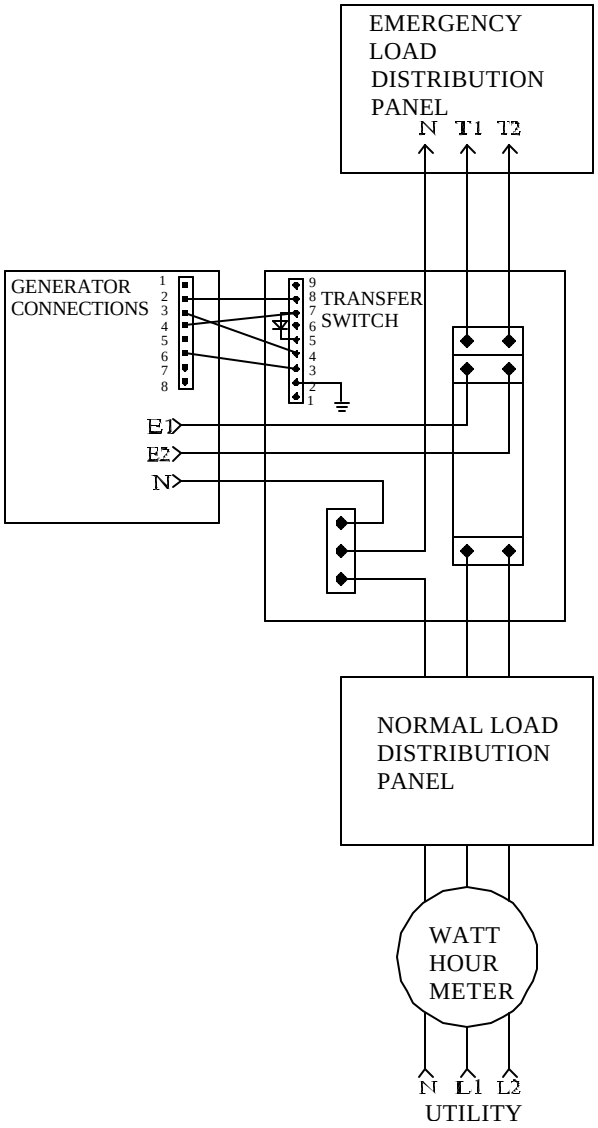
The battery will be supplied by the customer. The battery must have at least 235 cold cranking amps for a cold start for the 9kW, and the 15kW should have a minimum of 40 amp/hours. Recommended size for the battery is U1 lawn mower tractor battery. The dimensions must be 7.5”x 5” x 6.5”. To place the battery in the battery compartment, the screws on the top and side of the cover need to be removed. Place the cover and screws to the side. Once the battery has been placed and tied down, with the battery hold down bar, the leads can be connected to the respective battery post. Connect battery charger leads at the same time battery is connected. Always connect the positive cable first and the negative cable last, when disconnecting it is negative cable first and then positive cable last.

Caution: Failure to connect and disconnect in the proper sequence can cause equipment damage. Ensure there is a clean tight fit from the cables to the posts. Replace the cover and screws.

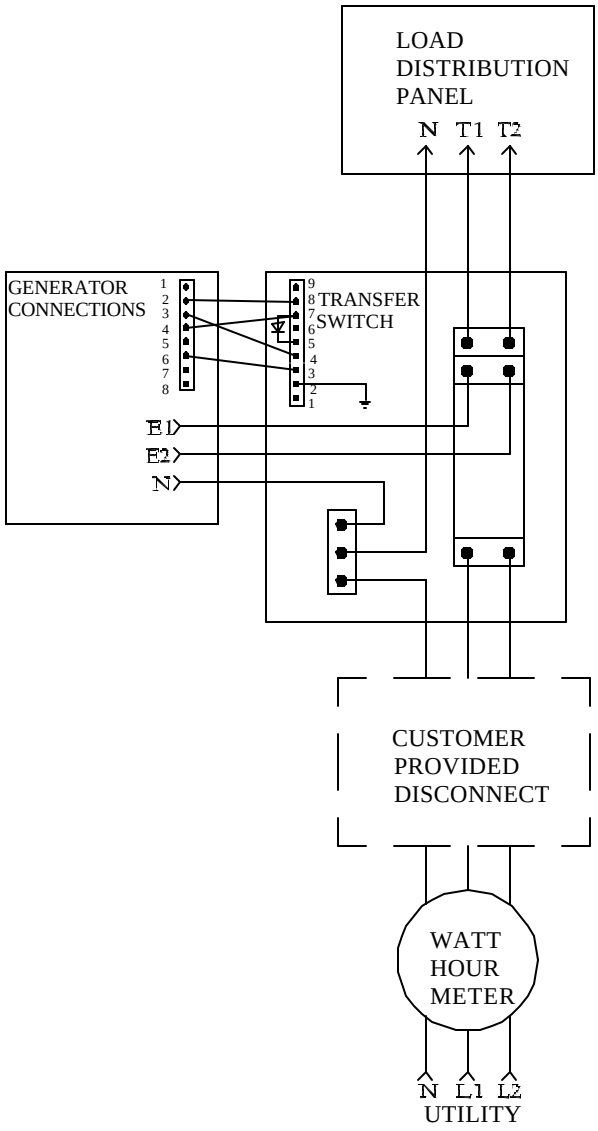
Note: At this time the main power can be turned back on. The ASCO Transfer Switch will light up with the exercise light flashing. Refer to the ATS manual for operation and settings of switch.

Recommended Installation Method

Note: The system wiring on recommended and alternative install is for the 9kW unit only.



Alternative Installation Method



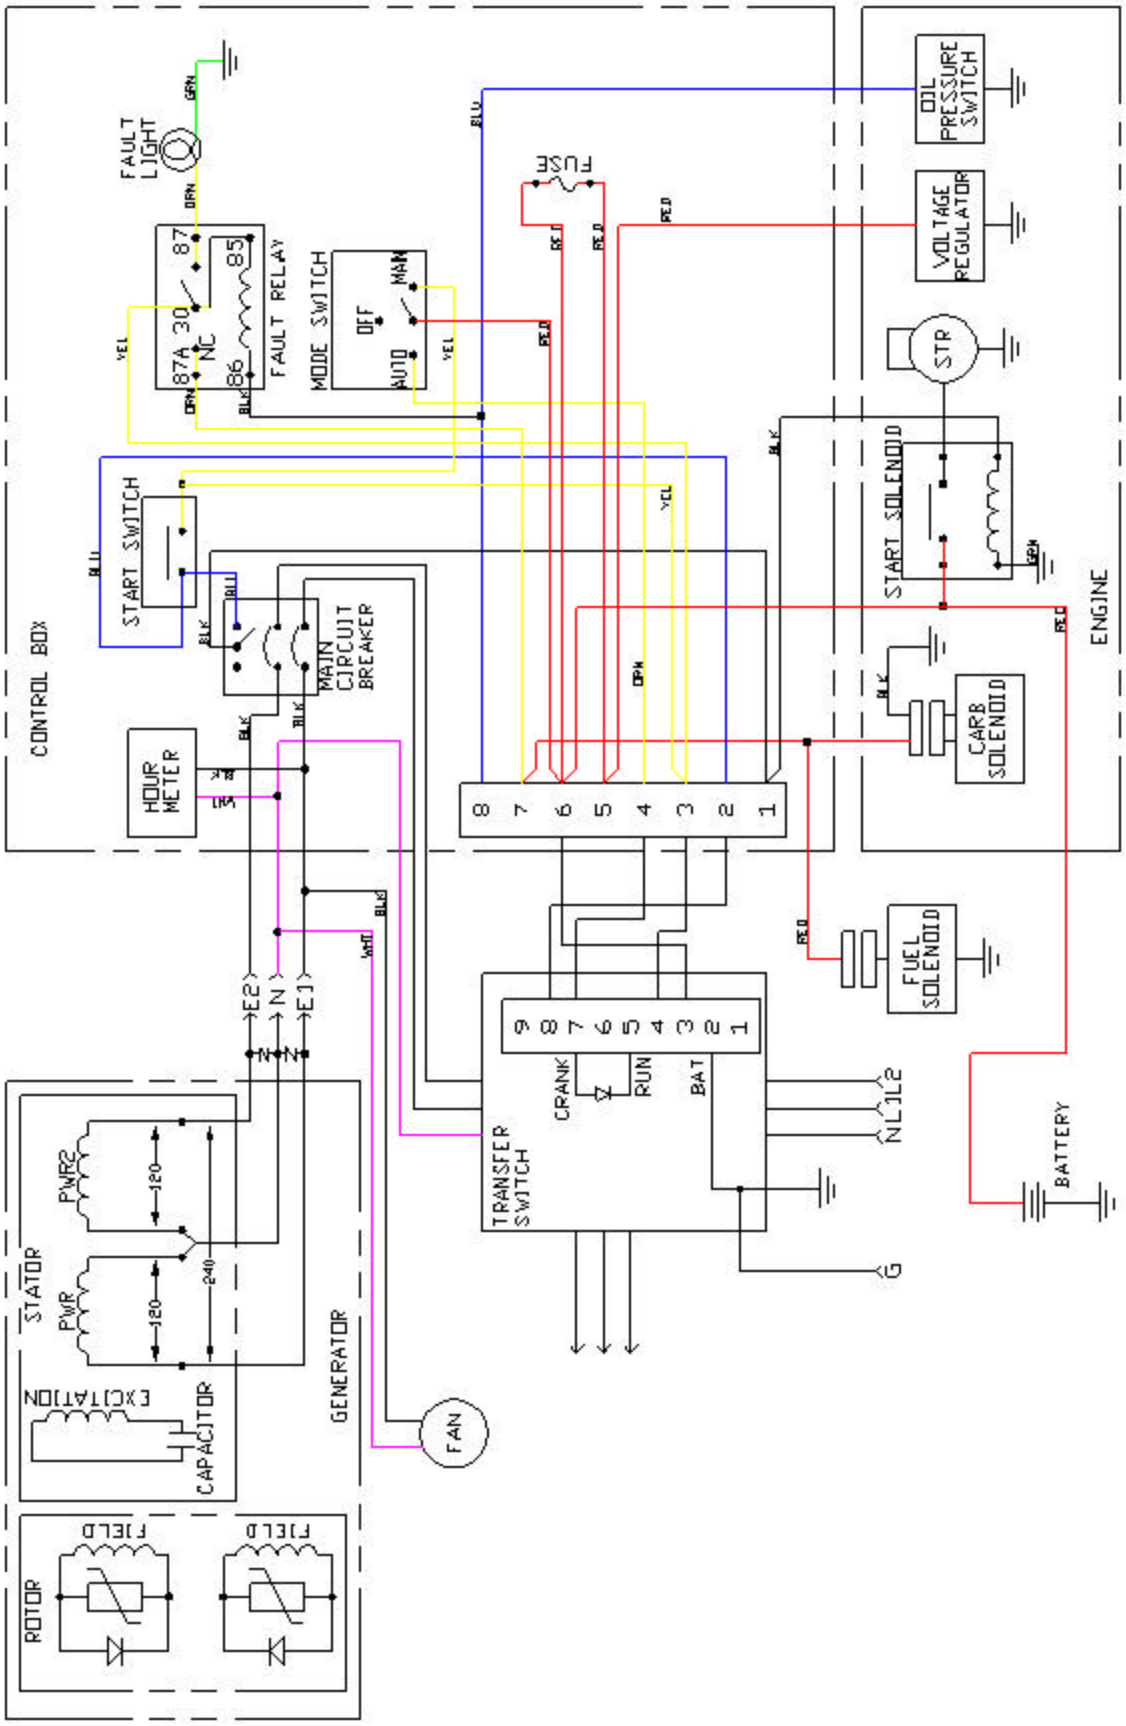
We recommend using an Emergency Distribution Panel when connecting the Lighthouse System to a house or business.

The System Interconnection Diagrams in this Generator Installation & Service Manual should be used when connecting the generator to the transfer switch. When connecting the ATS, refer to the Automatic Transfer Switch Owners/Installation Manual.

NOTICE:

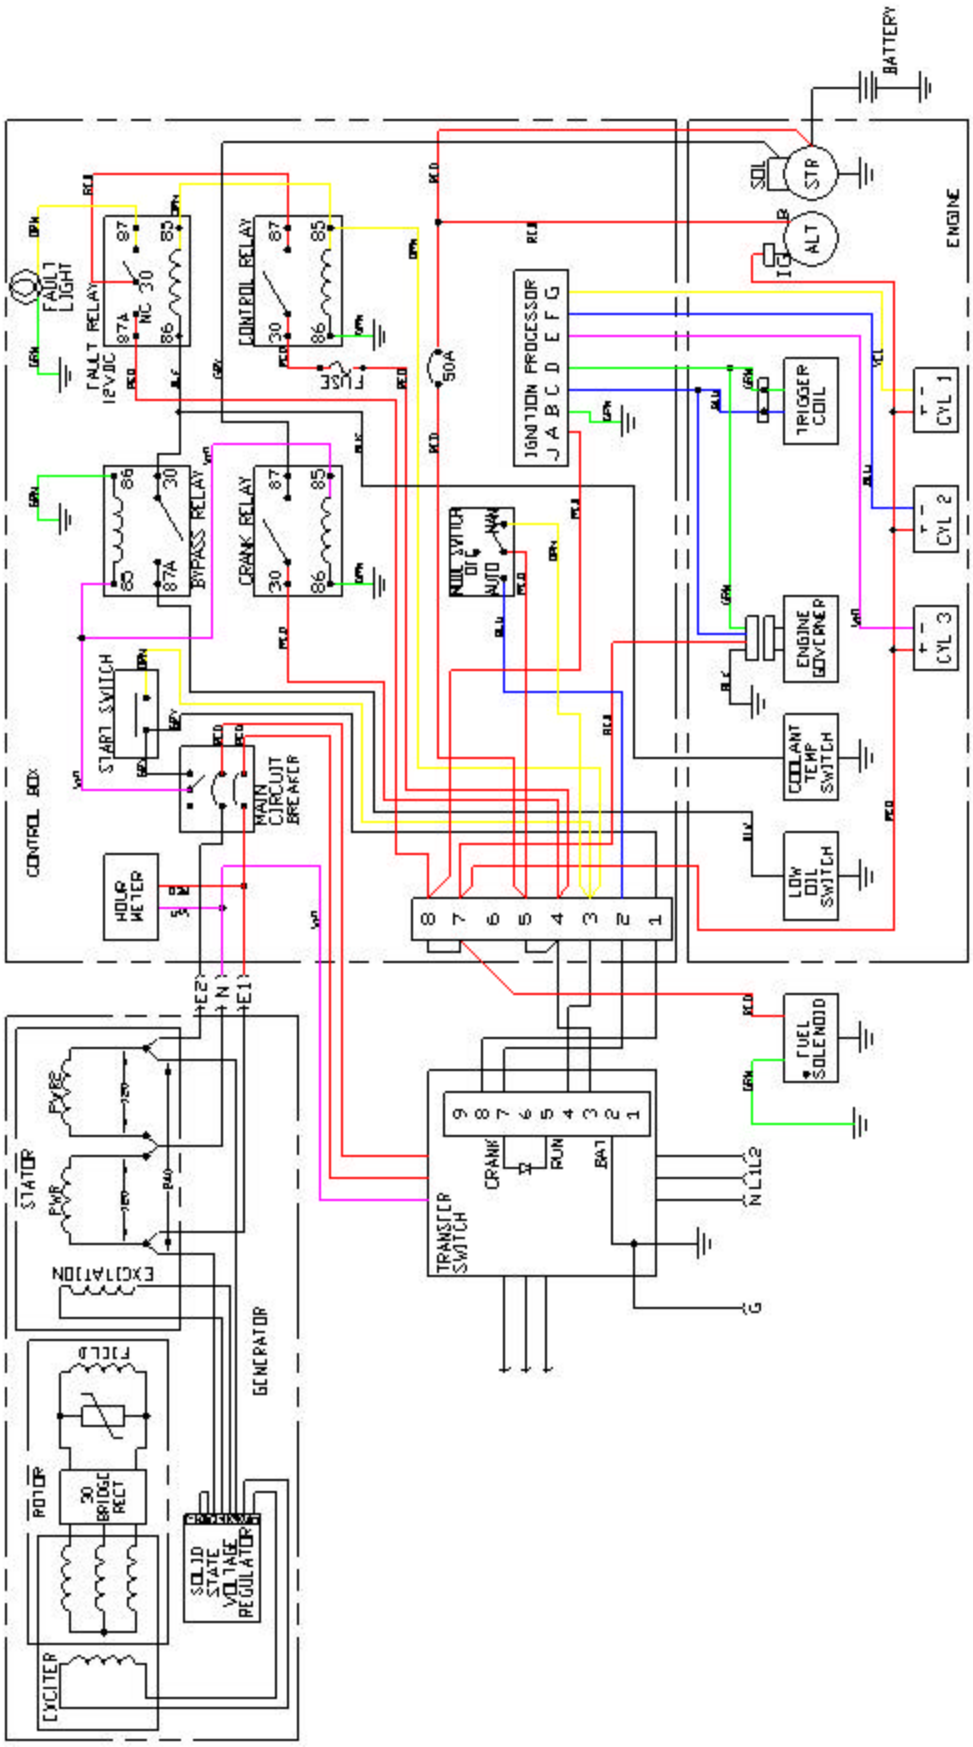
When the alternative method is used. The Transfer Switch is not service entrance rated. A disconnect must be installed, per NEC code, between the transfer switch and the utility supply.

NOTE: Wiring Schematic for 9kW unit only.



PAGE 7

NOTE: Wiring Schematic for 15kW unit only.



PAGE 8

SYSTEM START-UP CHECK

Inspect for the following:

1. Check for proper alignment of unit. Unit is square, side panels and lid. Unit is level.
2. Sufficient air space around unit, three feet on all four sides. Exhaust is pointed away from windows and doors.
3. Engine crank case is full of oil.
4. Fuel line is properly connected and routed with no leaks. Use soapy water in spray bottle to check.
5. Correct AC wire sizes and connections, and correct routing of line.
6. Correct DC wire sizes and connections, and correct routing of line.
7. Battery properly sized and mounted correctly.
8. Battery charger plugged in and wired correctly.

Start-up Procedure at Generator Location:

1. Make sure Mode switch is in the manual position. With circuit breaker on.
2. Turn the preferred source (utility) supply to the transfer switch off.
3. Connect AC volt and frequency meter to the alternator source.
4. Press the start button on the control panel and hold until engine starts, approximately 3 seconds or for 10 second intervals.
5. If unit fails to start refer to Troubleshooting Section D on page 11.

Engine Checks, No Load:

1. Adjust frequency and no load voltage if necessary.
   (No load voltage range shall be between 240-245. No load frequency shall be between 60-61 Hz).
2. Adjust engine speed up or down for no load specifications, voltage is not adjustable, 9kW units only.
3. Frequency and voltage are pre-set on the 15kW unit. Should not require adjustment.

Check Operation of ATS Switch per Loaded Volts and Frequency specifications:

1. Turn on the preferred source (utility) circuit breaker.
2. Turn on the alternate source (generator) circuit breaker. Mode switch to Auto.
3. Verify that utility (preferred source) acceptable light is on.
4. Verify that the transfer switch on utility (preferred source) light is on.
5. This step will start the generator. Press and hold the Push to Test button until generator (alternate source) acceptable light comes on and stays on. Then release the button.

   This light indicates that the generator is running and that its output voltage and frequency are acceptable. Under typical conditions, the light should come on after about 5 to 10 seconds. If the generator is running and fails to produce the proper voltage and frequency after 60 seconds then a malfunction has occurred, consult page 9 error codes.

6. About 15 seconds after the generator (alternate source) acceptable light comes on, the automatic transfer switch transfers the load from the utility to the generator. The transfer switch on generator (alternate source) light comes on.
7. At this time check the loaded volts and frequency at E1 and E2 (ATS). Voltage should not drop below 220 V and frequency should hold at 60 Hz. If unit does not meet specifications go to Generator Troubleshooting section. Page 15 of the manual.
8. Increase the amperage load by turning on appliances, lights, etc. Try to simulate a load which would be normal usage by the customer.
9. The transfer switch stays connected to the generator for 5 minutes. Then the load is transferred back to the utility. To bypass time delay, press and release the Push to Test button again.
10. After load retransfer to utility, the generator runs 1 minute (without load), then shuts down. The generator acceptable light goes off indicating that generator is off.

Check Automatic Operation of ATS by Shutting off Preferred Source (Utility).

1. The generator starting controls are set for automatic. Mode switch to Auto and circuit breaker on.
2. Turn the preferred source (utility) circuit breaker off. The utility source acceptable light goes off.
3. If the utility remains unacceptable for three seconds the automatic transfer switch cranks and starts the generator.
4. Once the generator starts, the automatic transfer switch waits until the generator voltage and frequency are acceptable. Then the generator source acceptable light comes on.
5. When the generator is acceptable, the automatic transfer switch waits 15 seconds to allow the generator to warm up. Then it transfers the load to the generator. The transfer switch on generator (alternate source) light comes on.
6. Increase the amperage load by turning on appliances, lights, etc. Try to simulate a load which would be normal usage by the customer.
7. Turn the preferred source (utility) breaker back on. When the utility again becomes acceptable the utility source acceptable light comes on.
8. The automatic transfer switch then waits 5 minutes to allow the utility to stabilize. Then it retransfers the load back to the utility. The transfer switch on utility (preferred source) light comes on.
9. After load retransfer the generator will continue to run unloaded for one minute for engine cool down. Then it is stopped. The generator acceptable light goes off.

TROUBLESHOOTING AUTOMATIC TRANSFER SWITCH

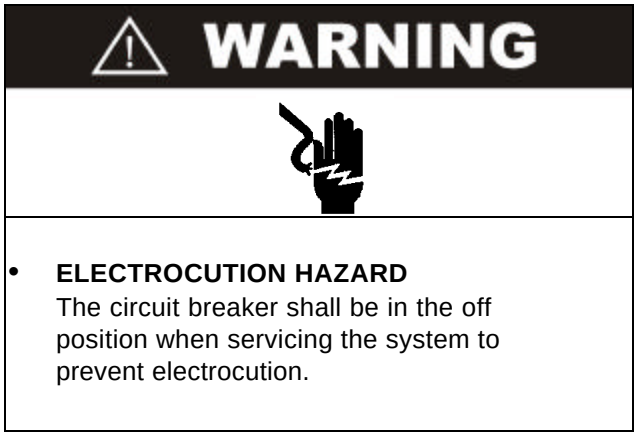
DANGER HIGH VOLTAGE; ELECTROCUTION - FLASH HAZARD
Do not replace parts in the transfer switch until both the utility and generator are off. Turn OFF both circuit breakers.

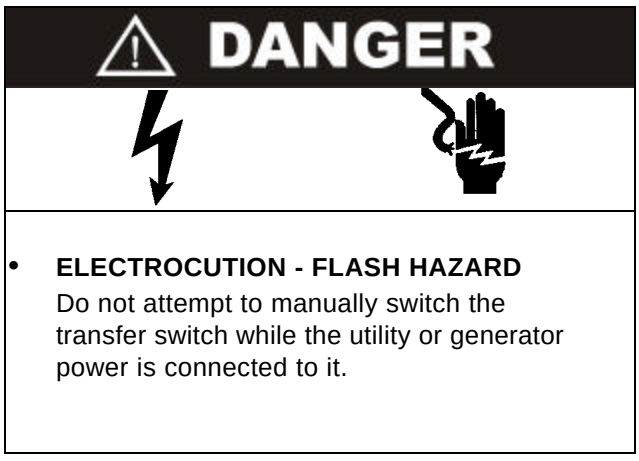
A. The UTILITY acceptable light does not come on when utility power is connected to the automatic transfer switch.

1. Verify that the utility feed is 240 V AC nominal and 60 Hz.
   CAUTION HIGH VOLTAGE PRESENT
2. Verify that the utility feed is wired to the terminal lugs on the bottom of the transfer switch marked L1 and L2.
3. Verify that the utility feed is connected and that its circuit breaker is ON.
4. With ALL POWER OFF, verify that the transfer switch harness is connected properly to the controller (plug at the bottom).

B. Power is connected (UTILITY acceptable light and/or GENERATOR acceptable lights are on) but both TRANSFER SWITCH position lights are off.

1. With ALL POWER OFF, verify that the transfer switch harness is connected properly to the controller (plug at the bottom).





C. Generator does not crank when the utility source fails or when the Push to Test button is pressed.

1. Verify that the generator starting controls are set for automatic operation, and that the generator circuit breaker is on.
2. Verify engine start low voltage wiring between controller terminal block TB7 (plug on the left) and the generator. Check
   that TB7 plug is properly seated in TB7 receptacle.
3. Verify that the generator battery is connected and that the battery voltage meets the generator manufacturer's recommendation.
4. Verify that the correct contact (normally open or normally closed) is being utilized (See the Generator Section).

D. Generator cranks but does not start when the utility source fails or when the Push to Test button is pressed.

1. Verify engine start low voltage wiring between controller terminal block TB7 (plug on the left) and the generator. Check that TB7 plug is properly seated in TB7 receptacle.
2. Verify proper generator operation (See Generator Manual).

E. The automatic transfer switch does not transfer the load to the generator (Generator "On" LED does not illuminate at ATS).

1. Verify that the generator source acceptable light is on. The transfer switch will not retransfer the load to the generator until the generator output is acceptable. If the light is off, verify that the circuit breaker for the generator feed is ON.
2. Wait 15 seconds, there is a 15 second delay after the generator output becomes acceptable to permit the generator to warm up.
3. If the generator source acceptable light still does not come on, see above problems C and D.

F. The automatic transfer switch does not transfer the load back to the utility (Utility “On” LED does not illuminate at ATS).

1. Verify that the utility source acceptable light is on. The transfer switch will not retransfer the load to the utility until the utility source is acceptable and the light is on. If light is off, verify that the circuit breaker from the utility feed is ON.
2. Wait 5 minutes, there is a 5 minute uninterrupted delay on retransfer to the utility.

G. The Generator source acceptable light does not go off after the automatic transfer switch retransfers the load back to the utility.

1. Wait 1 minute, after load retransfer to the utility, there is a 1 minute delay for generator cool down before shut down.

2. Verify proper operation of the generator (See the Generator Manual).

H. Both transfer switch position lights are flashing (this indicates an error condition).

1. Count the number of times the automatic generator exerciser light flashes (repeats after pause). This number is the error code.

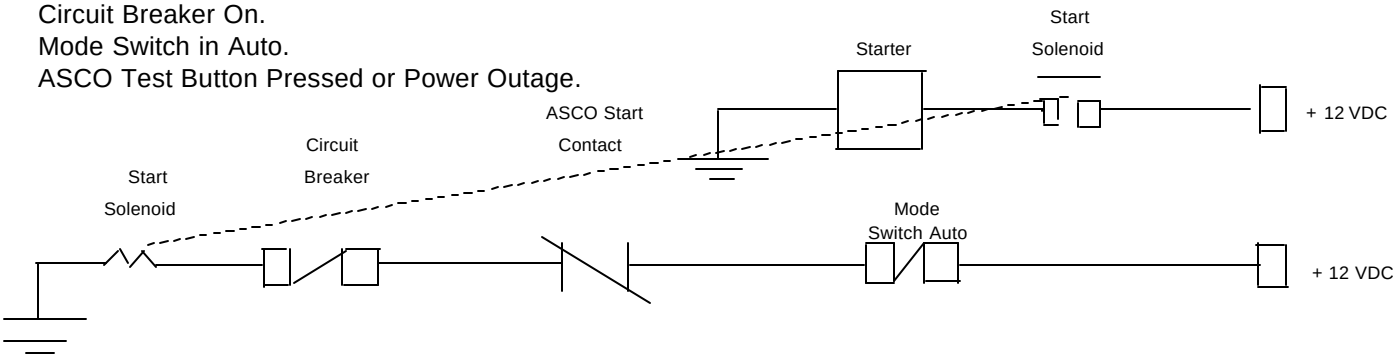
2. Error codes:	1 is unused / open
2 Generator failed to start.	See Problems C and D.
3 Generator failed after starting.	See Generator Troubleshooting Section.
4 Generator over or under frequency.	See Generator Troubleshooting Section.
5 Transfer Switch did not transfer the load to the generator.	Service required.
6 Transfer Switch did not transfer the load to the utility.	Service required.
7 Controller error.	Service required.

To clear error code, press and release Push to Test button.

TROUBLESHOOTING INDIVIDUAL CIRCUITS

A. Auto Crank Circuit Normal Run - No Faults

1. Conditions:
   Circuit Breaker On.
   Mode Switch in Auto.
   ASCO Test Button Pressed or Power Outage.



2. Operation: (Picture on page 12).
   a.) A power failure or pressing the ASCO test button applies 12 VDC to the start solenoid coil. Either of these states causes the crank relay to activate closing the crank contact momentarily.
   b.) The start solenoid coil closes the start solenoid contact applying 12 VDC to the starter.
   c.) The starter engages to the engine initiating cranking.

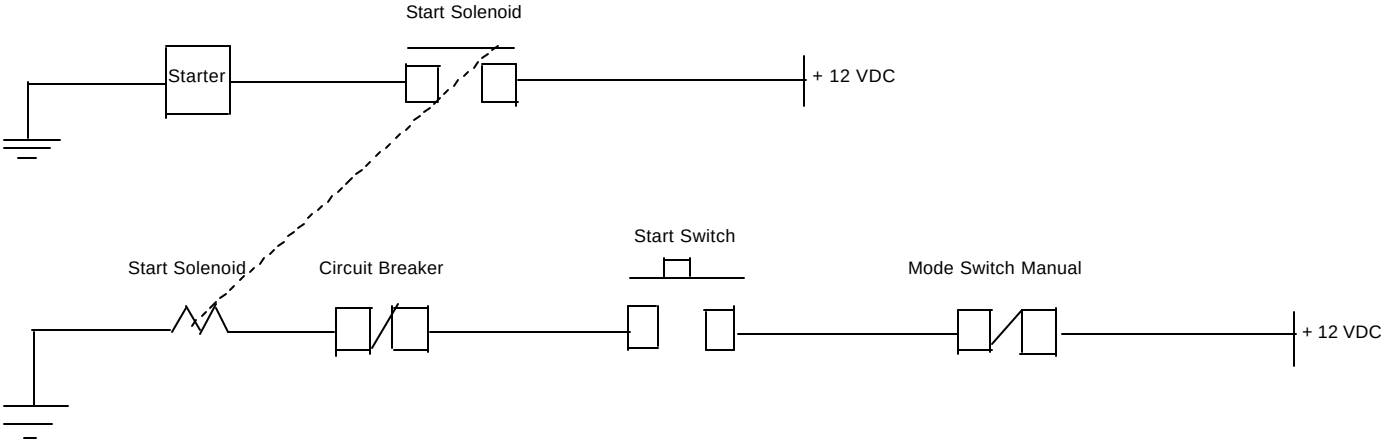
B. Auto Run Circuit Normal run - No Faults.

1. Conditions:
   a.) Circuit Breaker On.
   b.) Mode Switch in Auto.

   1.) The engine starts (see crank circuit).
   2.) Voltage is applied to the fuel and carb solenoids as long as the ASCO run contact is closed, and there are no faults. This ASCO run contact is controlled by power outages or test sequencers initiated by the test button.
   3.) Engine runs and generator set produces voltage to load.

C. Manual Crank Circuit Normal run - no Faults.

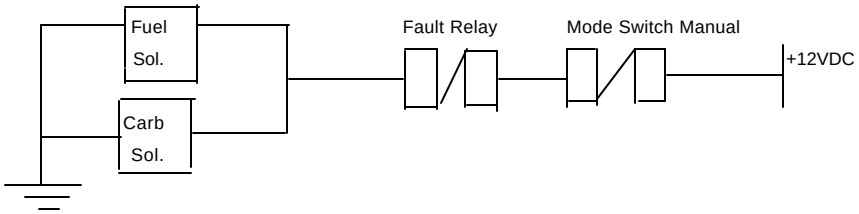
1. Conditions:
   a.) Circuit Breaker On.
   b.) Mode Switch in Manual Position.
   c.) Start Switch Pressed.



2. Operation:
   a.) Pressing the start switch applies plus 12 VDC to the start solenoid coil.
   b.) The start solenoid coil closes the start solenoid contact applying 12 VDC to the starter.
   c.) The starter engages to the engine initiating cranking.

D. Manual Run Circuit Normal run - no Faults.

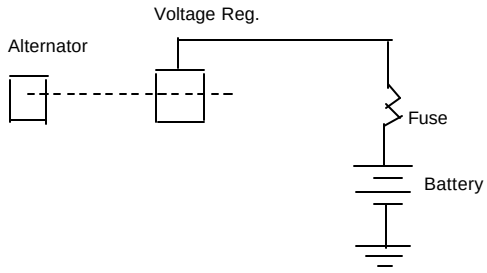
1. Conditions:
   a.) Circuit Breakers On.
   b.) Mode Switch in Manual.



2. Operation: (Picture on page 13).
   a.) The engine starts (see crank circuit).
   b.) Voltage is applied to the fuel and carb solenoids as long as the mode switch is in manual position and there are no faults.
   c.) Engine runs and gen set produces voltage to load.

E. Charge Circuit.

1. Conditions:
   a.) Unit is in one of its operating modes and generator is running.

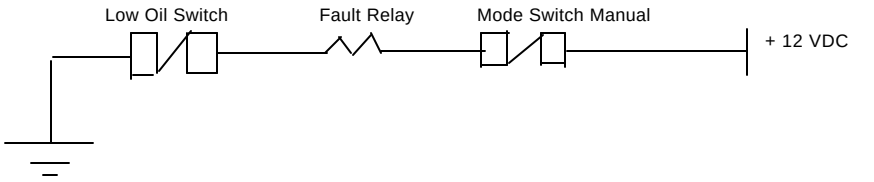


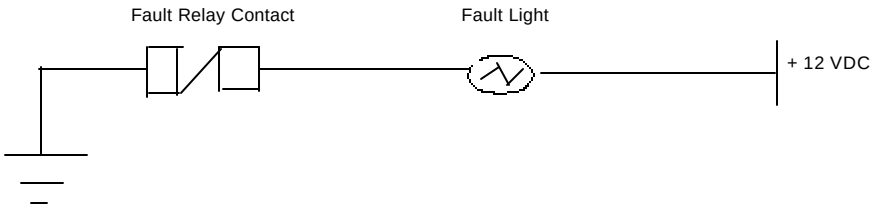
2. Operation:
   a.) The engine is on turning the alternator which produces a voltage to the voltage regulator.
   b.) The voltage regulator regulates the voltage to charge the battery.

F. Fault Circuit Manual Mode

1. Conditions:

   a.) Unit was running, Fault (low oil) occurred.



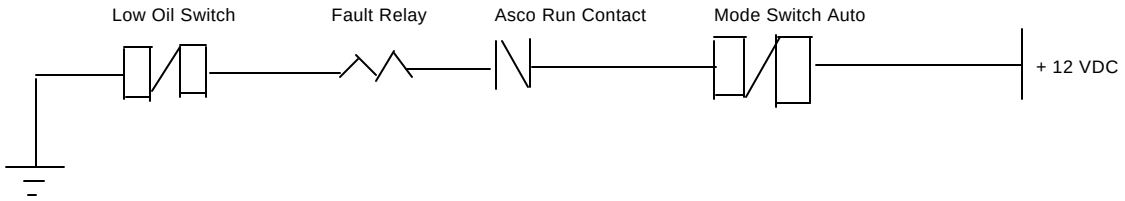


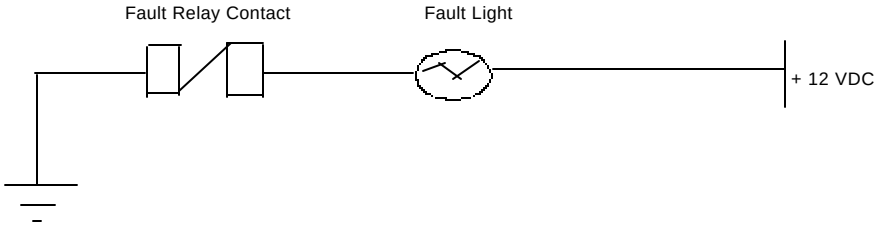
2. Operation:

   a.) Unit is running when the low oil switch closes.
   b.) Fault relay activates shutting unit down and lighting fault light.

G. Fault Circuit Auto Mode

1. Condition:
   a.) Unit was running, Fault (low oil) occurred.





2. Operation:

   a.) Unit is running when the low oil switch closes.
   b.) Fault relay activates shutting unit down and lighting fault light.

ELECTRICAL COMPONENT SPECIFICATIONS

A. Fuel Solenoid:
10.0 - 10.6 Ohms

B. Starter Solenoid:
Small Post to Ground 3.5 - 4.0 Ohms

C. Carb Solenoid:
29 Ohms

D. Fault Relay:
Post 30 to 87a = .2 Ohms
Post 85 to 86 = 90 Ohms
When 12 volts is put through 85 and 86 you will have continuity from 30 to 87.

E. Oil Pressure Switch:
.4 to .5 Ohms

TROUBLESHOOTING INDIVIDUAL CIRCUITS 15kW

Auto Mode Start Operation / Sequence -- Breakers Closed Fuse Good:

1. With battery hooked up there will be 12 volts at following locations; Starter motor terminal; “B” of Alternator, Pin 7 of transfer switch wiring harness; pin 30 of control relay, and pin 30 of crank relay.

2. When transfer switch senses a loss of power and initiates the start sequence the following things will happen:
   A. 12 volts is applied from transfer switch crank contacts, through main breaker to pin 85 of crank relay. This energizes relay applying 12 volts to start solenoid energizing it and engaging starter.

   B. 12 volts is applied from transfer switch crank contacts to pin 85 of bypass relay energizing it. This opens normally closed contacts 87A - 30 of bypass relay removing ground from oil pressure switch circuit.

   C. 12 volts is applied to pin 85 of control relay from run contacts of transfer switch, energizing it. This allows power to flow to pin 30 of fault relay from pin 87 of control relay.

   D. Oil pressure sensor switch is normally closed. This puts ground at pin 87A of bypass relay until pressure builds enough to open oil pressure sensor circuit.

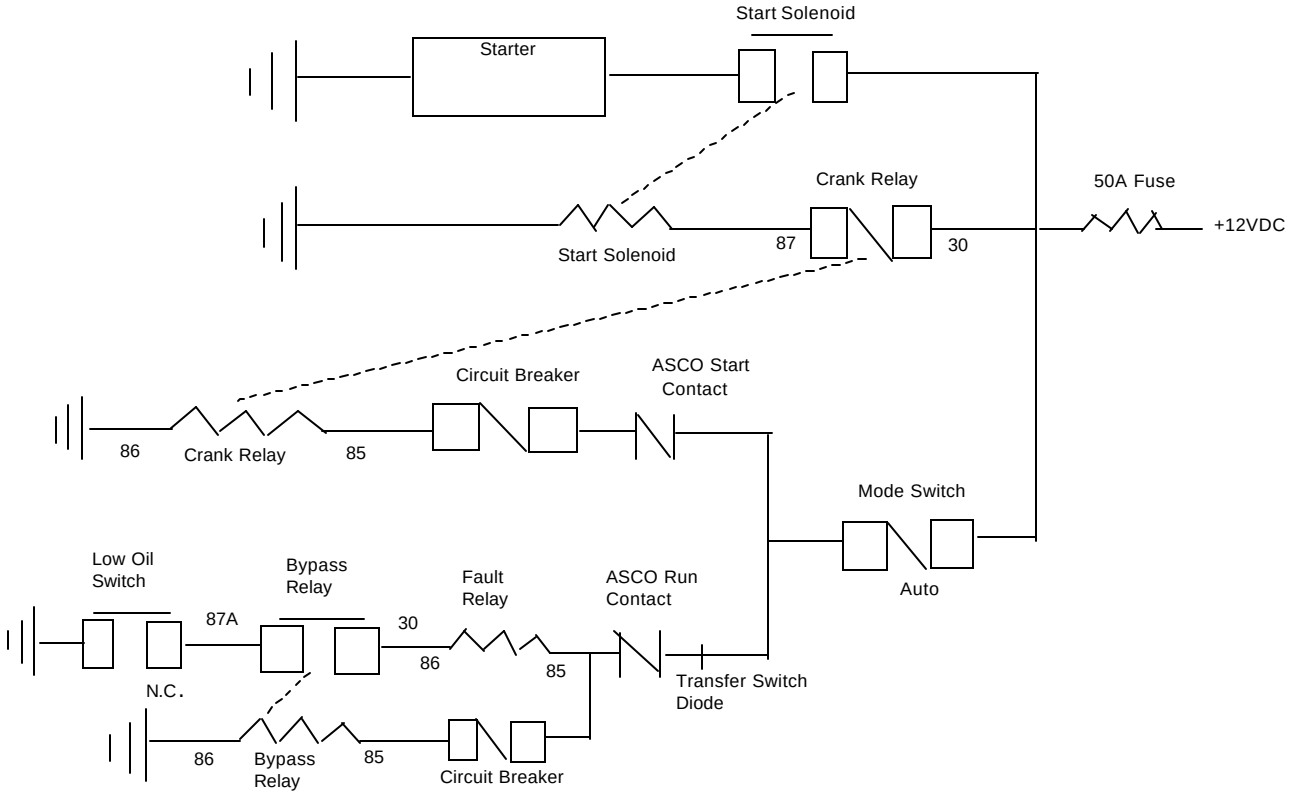
   E. If engine coolant switch is not closed (engine temp ok) it will have no effect. If engine coolant switch is closed (engine overheated) ground will be applied at pin 86 of fault relay. This will energize fault relay shutting engine down and activating fault light.

   F. If oil and temperature are both ok the fault relay will remain closed. 12 volts DC will be applied to fuel solenoid, governor, ignition processor, alternator, and cylinder coils. Engine will run and voltage will be produced.

3. Oil shut down circuit:
   A. Oil sensor is normally closed. This means ground is present when engine starts. During start sequence the coil in the bypass relay is activated opening contact 87A. This eliminates the ground that would normally feed through to pin 86 of fault relay. When the oil pressure builds the oil sensor switch opens removing ground. When the crank sequence ends terminal 87A and 30 make again. However, since ground is not present nothing happens. If oil pressure drops the oil sensor switch makes reapplying ground to terminal 87A of bypass relay on to terminal 86 of fault relay. This activates relay breaking contact 87A killing power to operating circuits and lighting the fault light though terminal 87.

A. Auto Crank Circuit Normal Run - No Faults

1. Conditions:
   a. Circuit breaker on.
   b. Mode switch in auto.
   c. ASCO test button pushed or power outage.

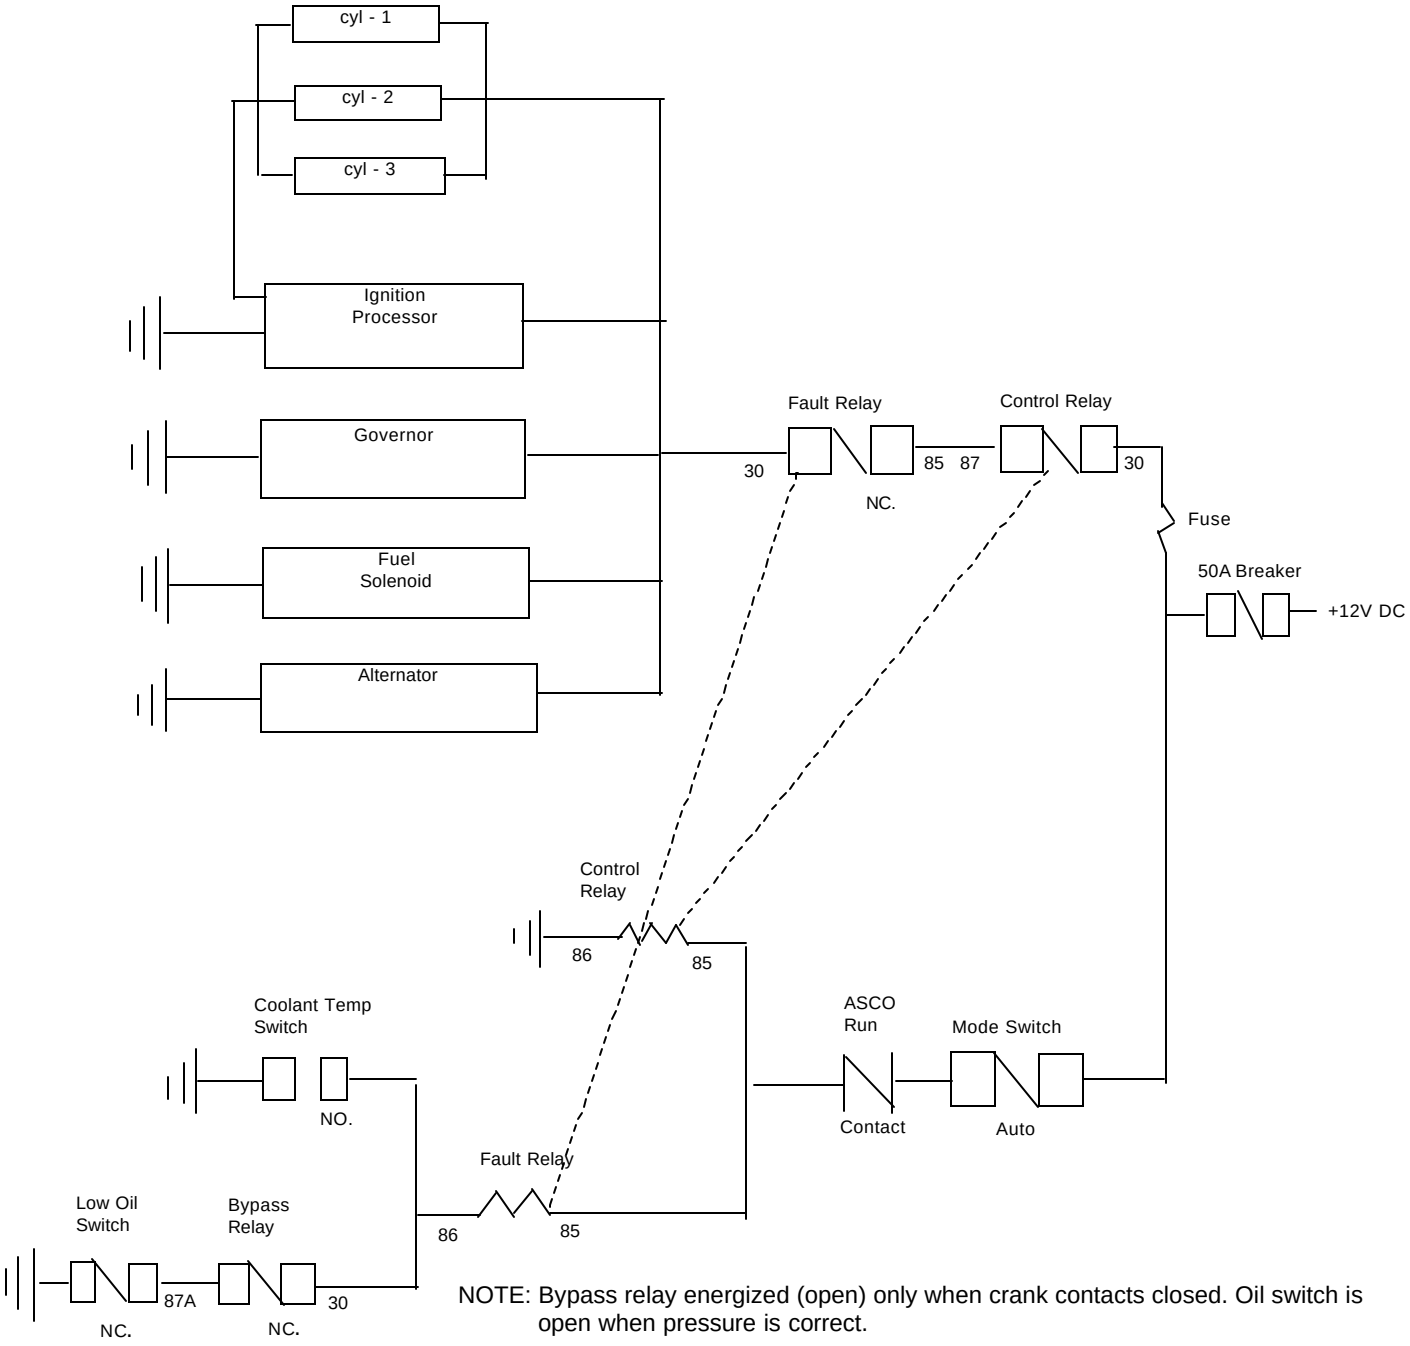


2. Operation:
   a. A power failure or pressing the ASCO test button applies 12VDC to crank relay energizing it.
   b. 12VDC is applied to start solenoid through crank relay.
   c. The starter engages engine initiating cranking.
   d. At same time 12VDC is applied through transfer switch diode through circuit breaker to bypass relay. Opening low oil sensor circuit.
   e. Low oil sensor pressurizes opening switch and removing ground from 87A of bypass relay in preparation of run sequence.

B. Auto run circuit normal run - No faults

1. Conditions:
   a. Circuit breaker on mode switch in Auto.

2. Operation:
   a. The engine cranks (see crank circuit).



NOTE: Bypass relay energized (open) only when crank contacts closed. Oil switch is open when pressure is correct.

   b. 12VDC is applied to control relay coil closing control relay.
   c. Voltage is applied to fuel solenoid, governor, ignition processor, alternator, and the three cylinder coils as long as the ASCO run contact is closed and there are no faults. The ASCO run contact is controlled by power outages or test sequences initiated by the test button.
   d. Engine runs and generator set produces voltage to load.

TROUBLESHOOTING INDIVIDUAL CIRCUITS 15kW

Manual Mode Start Operation / Sequence -- Breakers Closed Fuse Good:

1. With the battery hooked up there will be 12VDC at the following locations; starter motor terminal, “B” of alternator, pin 85 of control relay, pin 85 of fault relay, pin 30 of control relay and start switch.

2. When the start switch is pushed the following things happen;
   A. 12VDC is applied to pin 85 of crank relay closing relay and allowing 12VDC from pin 30 to pass through to start solenoid. This activates solenoid engaging starter.

   B. Oil pressure sensor switch is normally closed. This puts ground at pin 87A of bypass relay until pressure builds enough to open oil pressure sensor switch.

   C. 12VDC is applied to pin 85 of bypass relay energizing it. This opens normally closed contacts 87A - 30 of bypass relay removing ground from fault relay circuit.

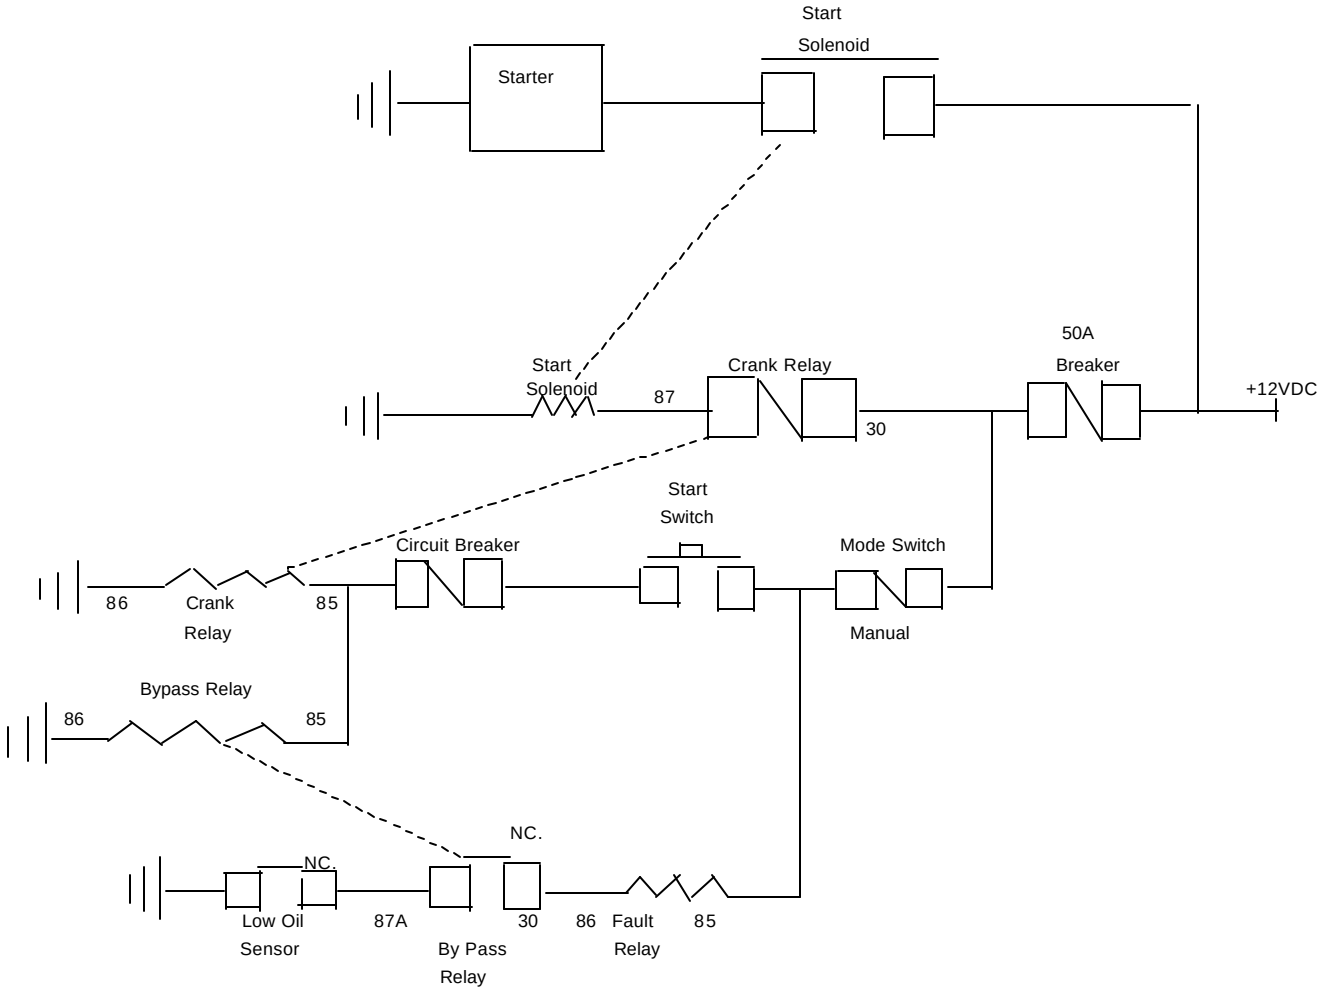
   D. If engine coolant switch is not closed (engine temp ok) it will have no effect. If engine coolant switch is closed (engine overheated) ground will be applied at pin 86 of fault relay. This will energize fault relay shutting engine down and activating fault light.

   E. If oil and temperature are both ok the fault relay will remain closed, 12VDC will be applied to fuel solenoid, governor ECU, ignition processor, alternator and cylinder coils. Engine will run and voltage will be produced.

3. Oil shut down circuit;
   A. Oil sensor is normally closed. This means ground is present when engine starts. During start sequence the coil in the bypass relay is activated opening contact 87A. This eliminates the ground that would normally feed through to pin 86 of fault relay. When the oil pressure builds the oil sensor switch opens removing ground. When the crank sequence ends terminal 87A and 30 make again. However, since ground is not present nothing happens. If oil pressure drops the oil sensor switch makes reapplying ground to terminal 87A of bypass relay on to terminal 86 of fault relay. This activates relay breaking contact 87A, killing power to operating circuits and lighting the fault light though terminal 87.

C. Manual crank circuit normal run - No faults.

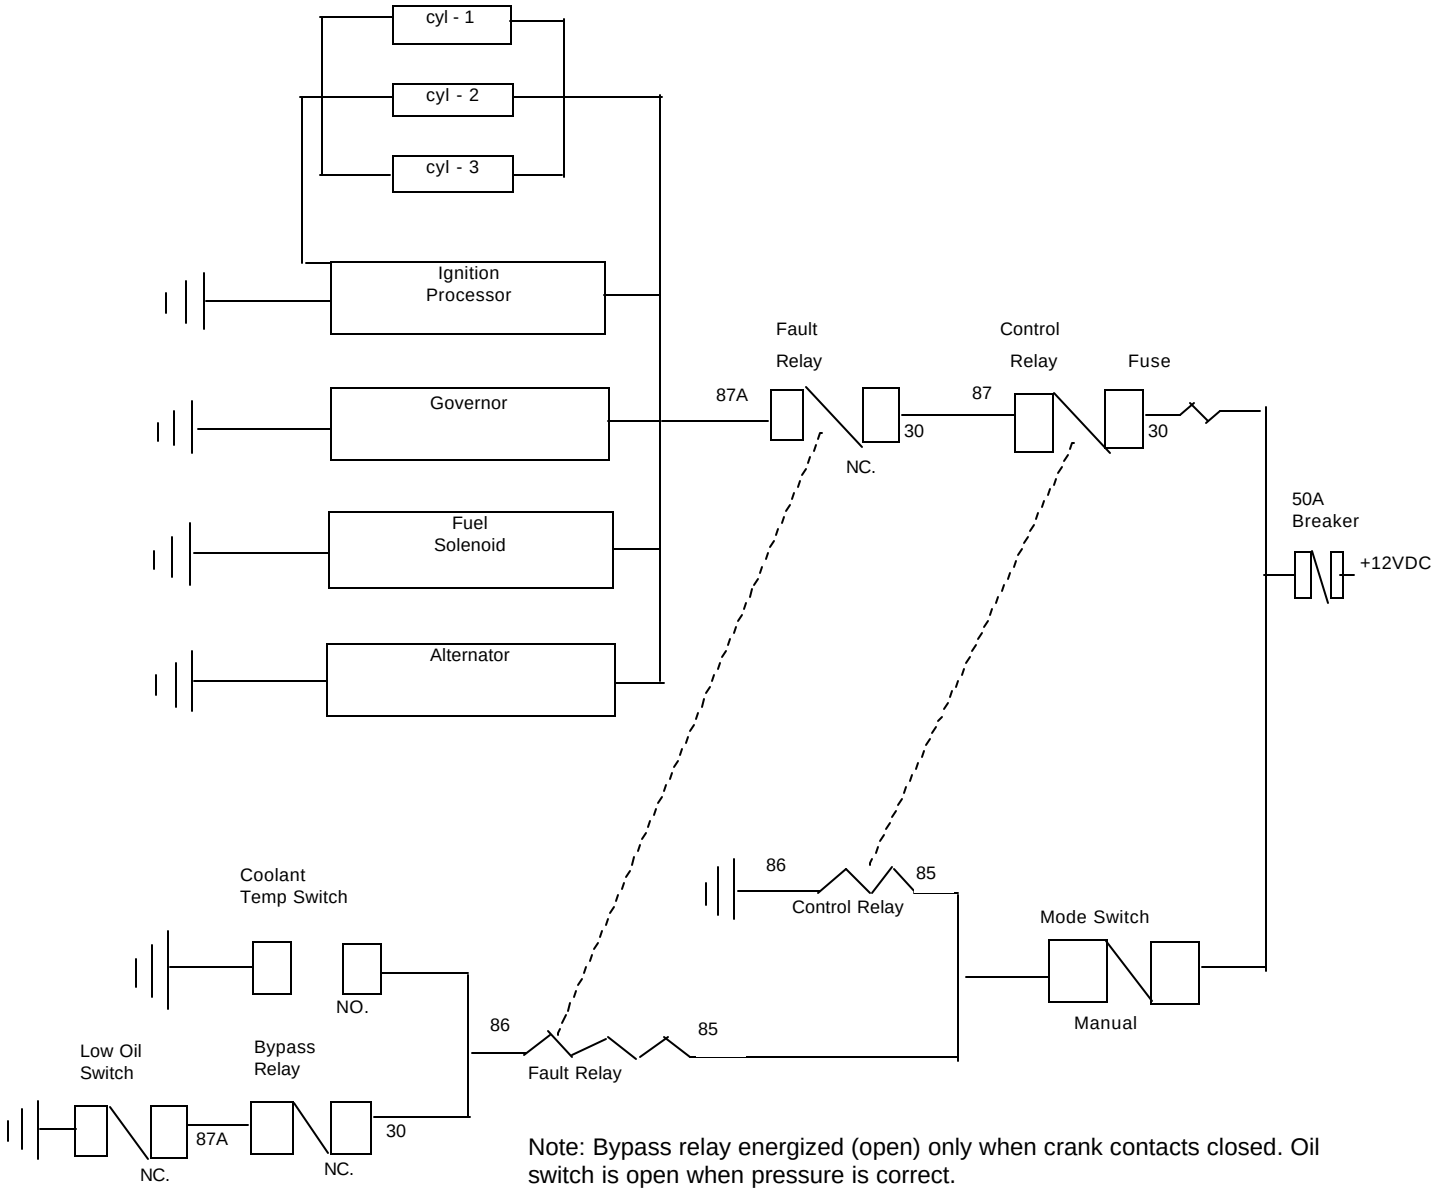
1. Conditions:
   a. Circuit breaker on.
   b. Mode switch in manual.
   c. Start switch pressed.



2. Operation:
   a. Pressing the start switch applies 12VDC to crank relay coil.
   b. Crank relay closes applying 12VDC to start solenoid.
   c. Start solenoid closes applying 12VDC to starter.
   d. Starter engages engine initiating cranking.
   e. At the same time 12VDC is applied to the bypass relay opening the low oil sensor circuit.
   f. Low oil sensor pressurizes, opening switch and removing ground from 87A of bypass relay in preparation of run sequence.

D. Manual run circuit normal run - No faults.

1. Conditions:
   a. Circuit breaker on.
   b. Mode switch in manual.



Note: Bypass relay energized (open) only when crank contacts closed. Oil switch is open when pressure is correct.

2. Operation:
   a. The engine cranks (see crank circuit).
   b. 12VDC is applied to control relay coil closing control relay.
   c. 12VDC is applied to fuel solenoid, governor, ignition processor, alternator, and the three cylinder coils as long as there are no faults.
   d. Engine runs and generator set produces voltage to load.

TROUBLE SHOOTING GENERATOR SECTION 9kW

A. Generator has no Output, Volts or Frequency:

1. Re-excite generator section with 12 volt battery. Control cover will have to be removed so excitation can be done by touching positive and negative wires to black (pos.) and white (neg.) main power posts.
2. Test capacitors, insuring they discharge and charge at the same rate, or that they have the proper MF readings.
3. Check Ohm's resistance reading for Stator and Rotor.
   Rotor - 5.9-6.0 Ohm's each winding.
   Stator - Black to White .30-.50 Ohm's
   Red to Red 1.4 to 1.6 Ohm's
   Green to Green 1.4 to 1.6 Ohm's

B. Generator will not pull load:

1. Check engine speed by measuring no load Volts or Hz readings.
   Volts - 240-245
   Hz - 60-61
2. Inspect engine for dirty or oil soaked air filter. Spark plug gap .030, plug wires connected correctly.
3. Fuel flow should be checked at utility side of regulator with manometer. Pressure should be 7 to 14" water column, or 4 to 8 oz. flow.
4. Diode on rotor has opened. Should only read continuity through diode in one direction.
5. Rotor has partial broken or open winding. Check resistance (Ohm's) of windings on rotor.
6. Dead short or open winding in stator. Check resistance (Ohm's) of windings in stator.

C. Engine will not start:

1. Check oil level, and low oil sender unit.
2. Check battery for full charge.
3. Check to make sure fuel is turned on. Fuel pressure should be 7 to 14" water column, or 4 to 8oz. flow.
4. Check starter solenoid. Should have reading between big posts. Should get a reading between the positive and little post when starter is engaged.
5. Check starter motor.

DISASSEMBLY AND ASSEMBLY INSTRUCTIONS 9kW UNIT

1. Remove lid by taking nyloc nuts and bolts off lid support arms. Close lid and remove mounting screws on back for hinges. Lift lid off unit and set a side. Disconnect battery cables and remove battery.
2. To remove front cover, turn middle two and bottom two screws one half turn counter clockwise to unlock. The top two are just pins, pull out on front cover and remove.
3. To remove engine end panel first make sure fuel is shut off at fuel supply. Remove fuel line from regulator. Remove all screws on end panel. Pull end panel out two inches to access mounting bolts for oil cooler, remove bolts and panel.
4. To remove generator end panel remove screws and panel.
5. To remove back panel disconnect AC and DC power cables. Remove screws and take off panel.
6. Remove the muffler heat shield.
7. Remove stator assembly. Unbolt stator isolators from stator bracket. Place block of wood under engine adapter. Use a three hook puller or rubber mallet to work stator assembly off unit.
8. Remove rotor assembly. Remove rotor bolt. With rubber mallet strike rotor shaft bearing at a 90' angle to break wedge loose. Hold on to rotor with free hand, when wedge breaks loose remove rotor.
9. Engine may be removed from frame at this time.

ASSEMBLY INSTRUCTIONS 9kW UNIT

1. Install four isolators to engine torque to 10-17 ft./lbs. (13.56 to 23.05Nm).
2. Install ground wire (star washer with lock) (starter side) two holes same side closest to shaft.
3. Attach engine to frame, four 5/16 nyloc nuts and flat washer. Torque to 10-17 ft./lbs.(13.56 to 23.05Nm). Attach ground wire to frame with star washer under wire head.
4. Bolt engine adapter to engine with solid side of adapter to the top, put blue loctite on adapter whiz bolts and torque to 10-17 ft./lbs.(13.56 to 23.05Nm).
5. Install rotor on engine shaft. Install 13mm nut and flat washer on rotor bolt, loctite engine end of bolt. Install rotor bolt and torque to 10 to 17 ft./lbs.(13.56 to 23.05Nm).
6. Install stator to adapter start lower bolt on exhaust side first with J clamp and nut with flat washer. J hook out, horizontal to frame, twist to 90 degree. With rubber mallet tap stator housing onto rotor bearing.
7. Loosen screw on governor spring retainer. Install manifold shield tightening screw governor spring retainer and installing shield screw on exhaust side.
8. Install three remaining adapter to gen head bolts nuts and flat washers torque to 10 to 17 ft./lbs.(13.56 to 23.05Nm).
9. Attach control box to top of stator housing.
10. Stator hook up; black to black. Remove nut and washer from right hand stud. Both small black ring terminals then second black, make sure terminals do not touch each other. Remove nut and washer two small white wires to one of the white posts. Attach ground (starwasher).
11. Engine wire hook up. Put harness into J hook. Attach blue wire to oil pressure sensor. Connect voltage regulator lead. Connect black insulated wire to solenoid. Connect red ring terminal to empty stud of starter and large red battery cable, pointing to the left.
12. Install muffler and muffler shield. Note; when tightening muffler hanger bolt do not put hole in muffler.

    NOTE: WHEN PUTTING IN THE #10-16 x .50 SCREWS WITH RUBBER WASHER DON'T OVER TORQUE. ONLY TIGHTEN UNTIL RUBBER WASHER FLATTENS OR 10 inch lbs. (1.13Nm)
13. Attach (genset) end panel, back side muffler shield first. Line muffler up closer to top. Tighten muffler clamp torque 8 to 12 ft./lbs.(10.84 to 16.27Nm).
14. Attach back panel; screw back panel to end panel first. Attach manifold to muffler shield. Attach muffler shield to back panel.
15. Set engine end panel to unit; hook up fan. Hook up red wire (solenoid) to regulator. Attach panel to back panel.
16. Oil cooler top hose goes to top fitting. Bottom hose goes to bottom fitting.
17. Hook up fuel line to regulator (clamp).
18. Attach ground wire (starwasher) attach propane ground wire.
19. Attach battery box. Feed cables into battery box.
20. Attach front panel.
21. Attach lid. Attach lid supports.
22. Test unit. Refer to page 9 and 10.

TROUBLESHOOTING GENERATOR SECTION 15kW UNIT

A. Generator has no output: Volts or Frequency

1. Re-excite the generator with a 12 volt battery, by touching just for an instant, pins 3 & 1 on the voltage regulator with a 30 Ohm resistor in series. Positive to pin 3, negative to pin 1 on regulator board.
2. Generator has no output after being excited. Check connections per attached drawings.
3. Check Ohm readings for stator and rotor.
   Stator windings:
   Exciter - Disconnect wire from terminal 1 on regulator board. Check across that wire to pin 3 on regulator board. Reading should be 15 - 17 Ohm.
   Auxiliary winding - Unfasten wires from pin 4 on regulator board. Use Ohm meter to determine which wire goes directly to V1. on the connector board. Measure from the other wire that was on pin 4 to pin 3 on regulator board. Reading should be 1.4 - 1.6 Ohm.
   Main winding - Measure between U2 & W1 and between V1 & V2 on connector board. Each should be .08 to .10 Ohm's.
   Rotor
   Excitor - There are 3 small red wires soldered in with the diodes. Should read 1.3 to 1.5 Ohm between any of the 3. Should read .7 to .8 Ohm between any of the small red wires and either of the large white wires.
   Main Winding - There are two large white wires on end of rotor soldered in with diodes. Should read 9 -10 Ohm across these.

CAUTION: Reading may very depending on accuracy and calibration of your meter. Use these readings as a general guideline.

B. Low Voltage / Frequency at no load:

1. Units are preset and adjusted at factory for proper voltage and frequency (240 - 245 volts & 59.5 - 60.5 Hz).
2. Both the generator and the governor on this unit will attempt to increase output to proper level. Check the engine RPM's, should be approximately 3700 RPM. If the RPM's are low, try to physically open up the governor. If the RPM's increase the problem is in the governor, replace governor. If the RPM's are correct, calibrate the voltage using the volts potentiometer on the regulator board. **CAUTION !** Move potentiometer very slowly. Small movement clockwise produces large increase in voltage.
3. Check windings for possible short.

C. High Voltage / Frequency at no load:

1. Check engine RPM's, should be approximately 3700. If RPM's are high try to physically close the governor. If the RPM's decrease and voltage comes down the problem is in the governor, replace governor.
2. If the RPM's are correct calibrate the voltage using the volts potentiometer on regulator board. **CAUTION !** Move potentiometer very slowly. Small movement counterclockwise produces large decrease in voltage.

D. Generator will not pull load:

1. Check engine speed by measuring no load voltage and hertz readings.
   Volts - 240 - 245
   Hertz - 59.5 - 60.5
2. Inspect engine for dirty or oil soaked air filter. Check spark plug for correct gap (.030). Plug wires connected correctly.
3. Fuel flow should be checked at utility side with manometer 7 - 14" water column.
4. Check fuel pressure at utility side 4 - 8 oz. psi.
5. Check diodes on rotor. Should only have continuity in one direction.
6. Rotor has partial short or open winding. Check Ohm reading on rotor.
7. Short or open winding in stator. Check Ohm reading on stator.

E. Engine will not start:

1. Check oil level and low oil sender unit.
2. Check battery for full charge.
3. Check to make sure fuel is turned on. Fuel pressure should be 7 to 14” water column or 4 to 8 oz psi.
4. Check starter solenoid. Should have reading between big posts. Should get reading between the positive and little post when starter is engaged.
5. Check starter motor.

DISASSEMBLY INSTRUCTIONS - 15kW UNIT

1. Remove lid by taking nyloc nuts and bolts off lid support arms. Remove locking screw from panel beside hinge. Slide lid of hinge pins.
2. Remove front cover by removing screws from panel at top on each side. Turn middle and bottom screws one half turn counterclockwise to unlock. Set front aside.
3. Remove front top brace by removing the two screws on each end of brace.
4. Remove generator end panel by removing the 4 screws from the back panel.
5. Make sure gas is turned off. Disconnect gas line from valve. Disconnect gas valve wires. Disconnect gas line from carberator.
6. Remove battery compartment lid. Disconnect cables and remove battery.
7. Remove the generator head cover. Disconnect the three wires coming from the control panel.
8. Remove cover from control box, disconnect AC & DC power cords. Disconnect wire block connector.
9. Remove 8 screws from back panel that hold the control and battery box and set aside.
10. Remove the 4 nuts holding the exhaust to the manifold.
11. Remove the screws from the back panel that hold it to the engine end panel.
12. Remove the back panel with muffler assembly and set aside.
13. Remove the 4 screws that hold the protecting screen over the generator air vent. Remove the 6 hex drive bolts inside that fasten generator rotor plate to engine plate. Remove the 8 bolts that fasten generator housing to engine housing. Remove the 2 bolts fastening generator to frame. The generator may now be removed.
    CAUTION: Unit is very heavy.
14. Drain radiator, remove hoses from engine. Remove radiator and panel and set aside.
15. Remove 2 bolts fastening engine to frame. Engine may now be removed.

ASSEMBLY INSTRUCTIONS - 15kW UNIT

1. Attach the 2 mounting brackets to the engine with 4 bolts. Torque 7 - 10ft./lb.
2. Attach antifreeze overflow bracket to mounting bracket on front side of engine.
3. Attach black ground wire to engine block on back side.
4. Remove governor from old engine and attach to new engine.
5. Attaching generator head. Remove the 4 screws holding the protective screen on the front of the generator.
6. Align the generator and the engine. Start 2 bolts through the generator into the engine housing on each side. Do not tighten. Attach lift bracket through the generator into the engine housing with 2 bolts. Finger tighten only.
7. Align the rotor plate on the generator with the engine plate. The generator flange must fit inside the engine plate. Start the 6 hex drive bolts through the generator flange into the engine plate. Finger tighten bolts only.
8. Raise unit and install 2 bottom bolts through the generator head into engine housing. Tighten all 8 bolts, torque to 30 - 50 ft./lb.
9. Make sure the generator flange fits snug into engine plate. Tap bearing on end of generator if necessary to move rotor forward. Generator flange should be approximately 1/32” inside engine plate. Tighten the 6 hex drive bolts inside generator, torque to 10 - 17 ft./lb.
10. Replace protective screen on generator. Place unit on metal frame and attach with 4 bolts.
11. Follow disassembly instructions in reverse to complete assembling metal cabinet.

25kW LIGHTHOUSE SERVICE MANUAL

WARNING: 1. This manual is only intended for Katolight Master Reps or Distributors.
2. Only Qualified Installers.
3. Before reading this manual please read all manuals accompanying unit.

The installation of this equipment must be done by licensed electrician's or contractor's and licensed gas technician or plumber's. Installation must be completed in conformance with NEC and local electrical and building codes.

INTRODUCTION

General Information

Read this manual carefully before operating or servicing generators to familiarize yourself with proper safety, operation and maintenance procedures. FAILURE TO COMPLY WITH INSTRUCTIONS IN THIS MANUAL COULD RESULT IN PERSONAL INJURY, PROPERTY DAMAGE AND/OR VOIDING OF THE WARRANTY. KATOLIGHT WILL NOT BE LIABLE FOR ANY DAMAGE BECAUSE OF FAILURE TO FOLLOW THESE INSTRUCTIONS. Check the unit over for any signs of freight damage.

This manual is not all inclusive. Each operating unit has a manual specific to its use.

Basic Generator Operations (Simplified)

The Lighthouse is manufactured for our customers to supply reliable emergency electrical power. The generator is a compact water cooled unit, designed to supply the power for your critical needs when utility power fails. Electric power is produced in the Lighthouse generators by a magnetic field rotating inside a stator. This is a brushless four pole type generator. To start producing electricity, it is the residual magnetism in the rotor's metal core which induces a small amount of current in the stator. This current is fedback into the rotor (increasing the magnetic field and the amount of current induced) until the rotor's magnetic field reaches saturation. At this point there is sufficient energy present in the stators output windings to operate the unit at its rated capacity.

Usage

The Lighthouse generator is connected with the home electrical distribution panel(s), via the transfer switch. It is intended that this unit be used in the following manner.

When the normal electrical service is interrupted the Automatic Transfer Switch (ATS) will signal the generator control circuit to start the engine. When the generator output voltage reaches a predetermined level, the ATS will automatically switch the load distribution panel to the generator output power. After utility service has been restored, the ATS switches the load back to the utility power and the generator shuts down after a short cool down period.

GENERATOR TERMINOLOGY

ALTERNATING CURRENT	Alternating current or AC is the flow of electrons in a conductor, first in one direction then in the other.
AMPERES (AMPS)	The rate of electron flow through a conductor is measured in amperes, which is a measurement of electrons flowing past a given point at a given time.
DIRECT CURRENT	Direct current or DC is the flow of electrons in only one direction through the conductor.
HERTZ	A unit of frequency equal to one cycle per second.
OHM	One Ohm is the amount of resistance that will permit one ampere of current to flow in a conductor when one volt of electro-motive force is applied.
ROTOR	The rotor is essentially an electro-magnet, since the flow of direct current through its windings creates a magnetic field around those windings. The strength of the magnetic field can be increased by (a) forming the wires into a coil, (b) increasing the wire size, or (c) increasing the current flow through the wires.
SINE WAVE	A wave diagram (sine wave) of alternating current shows that current goes from zero value to a maximum positive value, reversing itself again and returns to zero. Then it goes to a maximum negative value, reversing itself and returns to zero.
STATOR	The number of turns of wire in a stator winding are determined when it is manufactured. A typical stator assembly may be a single-phase type, or a three phase type. The greater the number of turns of wire in a stator winding, the greater the induced EMF when magnetic lines of flux cut through the windings.
VOLTS	The volt is the amount of electro-motive force (EMF) that will result in a current (electron) flow of one ampere through a resistance of one Ohm.
WATTS	One watt is equal to one ampere of current flow under pressure of one volt. Calculate electrical power by using the formula: WATTS = VOLTS x AMPERES.

UNIT SPECIFICATIONS

Generator

Rated Wattage - (Standby) 25,000 Watts at 1.0PF LPG
25,000 Watts at 1.0PF NG
Voltage - 120/240 volts
Rated Current - 208/104 amps LPG
Frequency - 60 HZ
Power Factor - 1.0
Max. Ambient Temp Rise - 105°C
Insulation class - H

Note: Rated wattage is specified at sea level, 60°F ambient temperature and propane fuel (with2500BTU/Cu.Ft).

Rated wattage decreases approximately 3.5% for each 1000 Ft. above sea level and approximately 1% for each 10°F above 60°F ambient temperature. For operation with Natural Gas (1000BTU/Cu.Ft). rated power will decrease approximately 10% below the propane rating.

Engine

Ford 2.5 - Liter
Type - Water cooled inline (4 cylinders)
RPM - 1800
Displacement - 2500cc (153in^3)
Bore X Stroke: 3.78in X 3.40in.
Compression Ratio: 9.37:1
Valve Arrangement - Overhead Valve
Governor - Electronic, Isochronous
Ignition System - Solid State
Starter - 12vdc, Solenoid Shift
Alternator - 12vdc, 90A
Oil Capacity - 4.0 qt. (3.79L) without filter, 4.50 qt (4.26L) with filter change.
Oil Filter - FL 300 (Ford)
Radiator capacity - 2.5 gallons, (9.46L). Shipped with 50/50 mix of water and propylene glycol antifreeze.
Spark Plug - Motorcraft AWSF 52C.
Battery - BCI Group 26, minimum 550 CCA, side posts for ring terminals on battery cables.

Fuel

Minimum Content Requirements:
1000 BTU’s per cubic foot for Natural Gas(NG)
2520 BTU’s per cubic foot for Liquid Propane Vapor (LPG)
Fuel supply pressures must be between 4oz (7” w.c.) and 6oz (11” w.c.) at inlet to the unit.

Consumption at Full Load:
345 cubic feet per hour of Natural Gas (NG)
3.77 gallons per hour of Liquid Propane Vapor (LPG)
(1 gallon is equal to 4.26 pounds LPG)

Dimensions

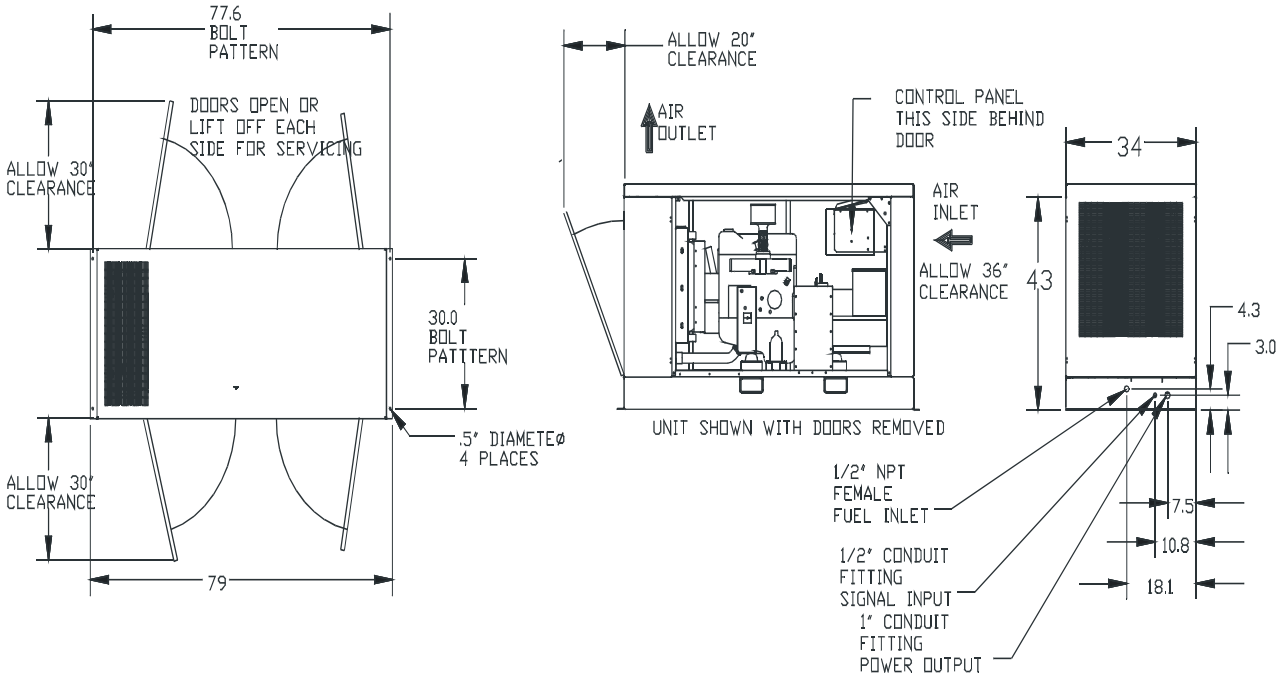
79”L x 34”W x 43”H (See next page for installation drawing).
Shipping Weight: 1525 lbs.

INSTALLATION

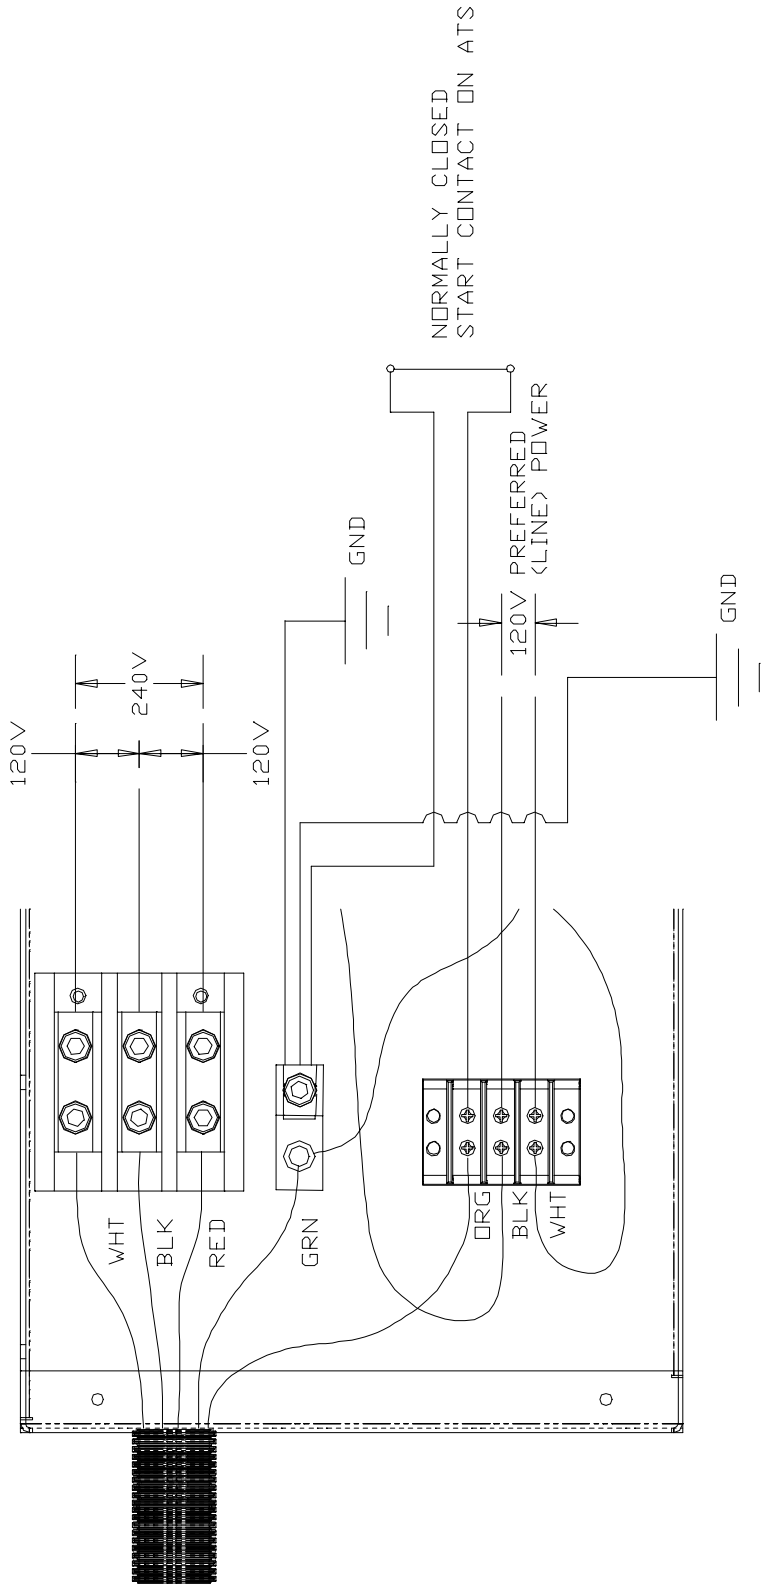
Site Selection and Preparation

Location - The unit should be placed in an area that allows plenty of room around the generator for ventilation and maintenance. Approximately three feet on each side. Covering or restricting the air passages on the sides of the generator units will cause the unit to overheat. Examples would be landscaping, piles of leaves, or piles of snow. Leaving a three foot open area around the unit will help in preventing any over heating. When placing the generator, the direction of the exhaust should be pointing away from windows, doors and any ventilation systems. **Do not install indoors.** The recommended method to remove the generator from the pallet and place it on a pad is to use a forklift, running the forks through the cross tubes.

Cement Pad - The unit should be bolted on a wire reinforced cement pad that is four to six inches thick. Holes have been placed in the frame for this purpose as shown in the diagram. The unit is mounted to the frame on rubber isolators to make the unit run as vibration free as possible.



JUNCTION BOX CONNECTIONS



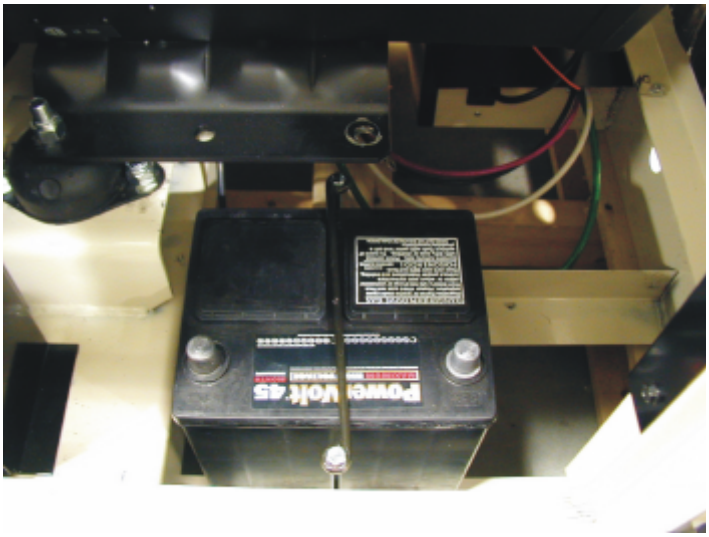
We recommend using an Emergency Distribution Panel when connecting the Lighthouse System to a house or business. The System Interconnection Diagrams in this Generator Installation & Service Manual should be used when connecting the generator to the transfer switch. When installing and connecting the ATS, refer to the Automatic Transfer Switch Owners/Installation Manual to make all connections.

BATTERY INSTALLATION

Minimum recommended battery size is a BCI Group 26 with a minimum of 550 CCA (Cold Cranking Amps). Place the battery in the battery rack as shown and secure using the hold down hardware provided. Once the battery has been placed and tied down with the battery hold down bar, connect the leads to the respective battery post. Always connect the (red) positive cable first and the negative (black) cable last. When disconnecting remove negative cable first and then positive lead last. The 25kW has ring terminals on the battery cables for use with side post batteries.

Note: The battery charger will automatically charge the battery to keep a full charge. This charger is connected to your normal electrical supply to keep your battery charged while the generator is idle.

The charger is not intended to recharge a battery which has become completely discharged.



⚠ WARNING

- ACID BURN
  Battery electrolyte fluids comprised of sulfuric acid that can be very dangerous and cause severe burns.
- Do not allow this fluid to contact eyes, skin, clothing, etc. If contact or spillage does occur, flush the area with water immediately.

⚠ WARNING

- EXPLOSION HAZARD
  Batteries contain sulfuric acid (when filled) and may emit explosive gasses.
- Read and follow safety instructions accompanying the battery.
- Keep sparks, flames and cigarettes away.
- Hydrogen gas is generated during charging and discharging.
- Always shield eyes, protect skin and clothing when working near batteries.

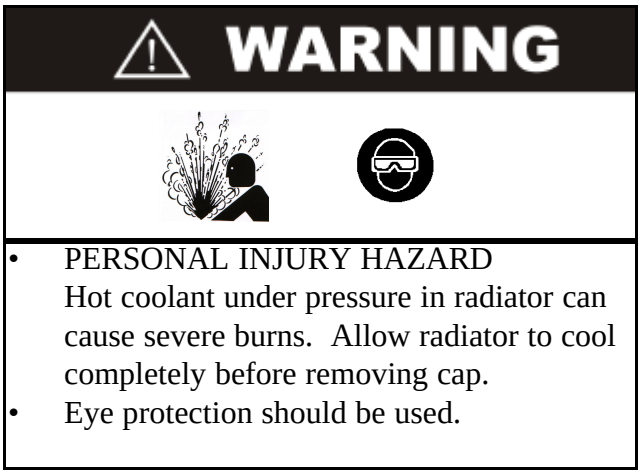
⚠ CAUTION

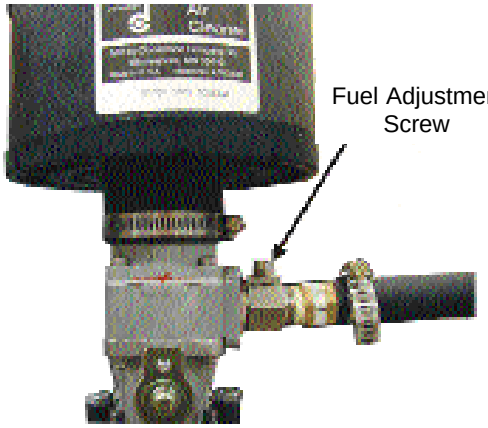
- Caution: Failure to connect and disconnect in the proper sequence can cause equipment damage. Ensure there is a clean, tight fit from the cables to the post.

LUBRICATION AND COOLING

Check oil level before start-up. The unit is shipped with the proper type of oil in the crankcase for operation above 40°F, (30W motor oil). Follow the engine manufacturer's recommendations for oil at temperatures below 40°F. Check oil periodically to ensure that unit is properly lubricated. Follow the engine manufacturer's recommended service schedule. Engine oil capacity is 4.0qt. (3.79L) without a filter change and 4.50qt. (4.26L) with a filter change.

Before initial start-up of the unit, check the coolant level in the radiator. Low coolant levels can cause insufficient engine cooling and possible engine damage. The unit is shipped with a 50/50 mix of water and propylene glycol antifreeze in the radiator. Check coolant levels and concentration periodically, especially in extreme climates. Follow engine manufacturer's recommended service schedule. If radiator is drained and refilled, make sure to disconnect bypass hose to purge air from radiator and engine head water passages.





CARBURETOR ADJUSTMENTS

Natural Gas Settings: Lighthouse units are tested with Natural Gas before they leave the factory. If Natural Gas is to be used no adjustments are required. The fuel select switch, located on bottom of control panel, should be in the NG position. The NG position is with the switch depressed away from front of control panel.

Propane Vapor Settings: The fuel select switch position is with the switch depressed toward the front of the control panel. (Fuel select switch is shown in picture of control panel on next page). The main adjustment screw is located on the side of the fuel mixer, as shown in illustration above. Start unit at no load and verify proper operation. Loosen jam nut on adjusting screw. Slowly load unit to full load, adjusting load screw counter-clockwise as required to achieve maximum power. Once smooth full load operation is achieved, tighten adjustment screw jam nut, then return unit to no load to verify proper operation. **Connection to gas supply MUST BE done by a licensed plumber or licensed gas technician and must comply with applicable building and local codes.**

FUEL REQUIREMENTS

For the best operation of the Lighthouse unit the fuels used should have a minimum content of 1000 BTU's per cubic foot for Natural Gas (NG) and 2520 BTU's per cubic foot for Liquid Propane Vapor (LPG). Contact local fuel supplier for local BTU content. Fuel supply pressures must be between 4 oz. (7" w.c.) and 6 oz. (11" w.c.) at the inlet to the unit.

FUEL CONSUMPTION

The Lighthouse 25kW at full load consumes 345 cubic feet per hour of Natural Gas (NG) and 3.77 gallons per hour of Liquid Propane Vapor (LPG).

⚠ WARNING

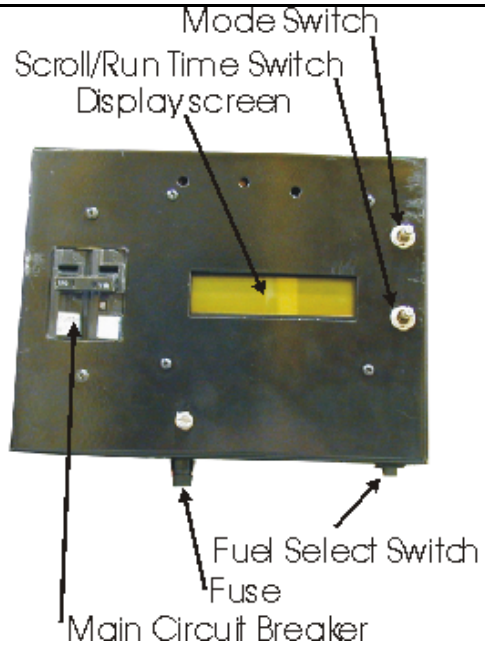
- EXPLOSION HAZARD
  Natural Gas is highly explosive.
- Natural Gas is lighter than air and will collect in high places.
- Extreme caution should be taken when working on a new installation or while performing general maintenance.
- Do not smoke or use open flame during maintenance.

⚠ WARNING

- EXPLOSION HAZARD
  Liquid Propane is highly explosive.
- Liquid Propane vapor is heavier than air and will collect in lower places.
- Extreme caution should be taken when working on a new installation or while performing general maintenance.
- Do not smoke or use open flame during maintenance.

CONTROL PANEL

The control panel contains a mode switch with a fault light, display panel and main circuit breaker.



MODE SWITCH

The mode switch has three positions, AUTO, OFF and MANUAL. This will control the operation of the unit. With the mode switch in the OFF position, the generator will not operate. This position of the switch should be used when the generator is being serviced or for an emergency stop. In the MANUAL position, the engine cranks and starts when the switch is moved to this position. This switch position should be used during testing or for manual operation of the system. In the AUTO position, the unit will operate in an automatic mode when utility fails.

MAIN CIRCUIT BREAKER

This circuit breaker is provided to disconnect the generator output from a load in the event of a current overload. (110 amp 240 volt)

DISPLAY SCREEN

The LCD screen displays the status of the generator system at all times. With the MODE switch in the OFF position, the display flashes a NOT IN AUTO message and displays battery voltage. Placing the Mode switch in the AUTO position causes the display to read IN AUTO and display battery voltage. Placing the Mode switch in the MANUAL position causes the display to read IN MANUAL and display battery voltage. When the generator is running, the display scrolls through voltage and amperage for each phase, while continuously displaying output frequency and battery voltage. In the event of a generator fault, the specific fault is displayed.

SCROLL/RUN TIME SWITCH

This switch is used to scroll through the controller display screens or to display the accumulated unit run time.

SCROLL LOCK POSITION

Moving the switch to this position will freeze the VOLTS, PHASE, and AMPS display. Placing the switch back to the center position resumes scrolling.

RUN TIME POSITION

Moving the switch to the RUN TIME position will display the accumulated hours on the genset. Hours displayed are the total number of hours the set has run since new.

FAULT LIGHT

In the event of a generator fault, the fault light illuminates until the controller is manually reset. When the fault light is illuminated the specific fault is displayed on the controller display screen.

RELAY CIRCUIT FUSE

The crank and fuel solenoid circuits are protected via an inline 10A fuse. If the engine does not crank or shuts down without displaying a fault, check the fuse by turning the fuse holder cap clockwise to remove the fuse.

FUEL SELECT SWITCH

The Fuel Select Switch located on the bottom side of the control panel selects either Natural Gas or Liquid Propane Vapor. When the Fuel Select Switch is depressed away from the Control Panel face, that is the Natural Gas position. When the Fuel Select Switch is depressed toward the Control Panel face, this is the Liquid Propane Vapor position.

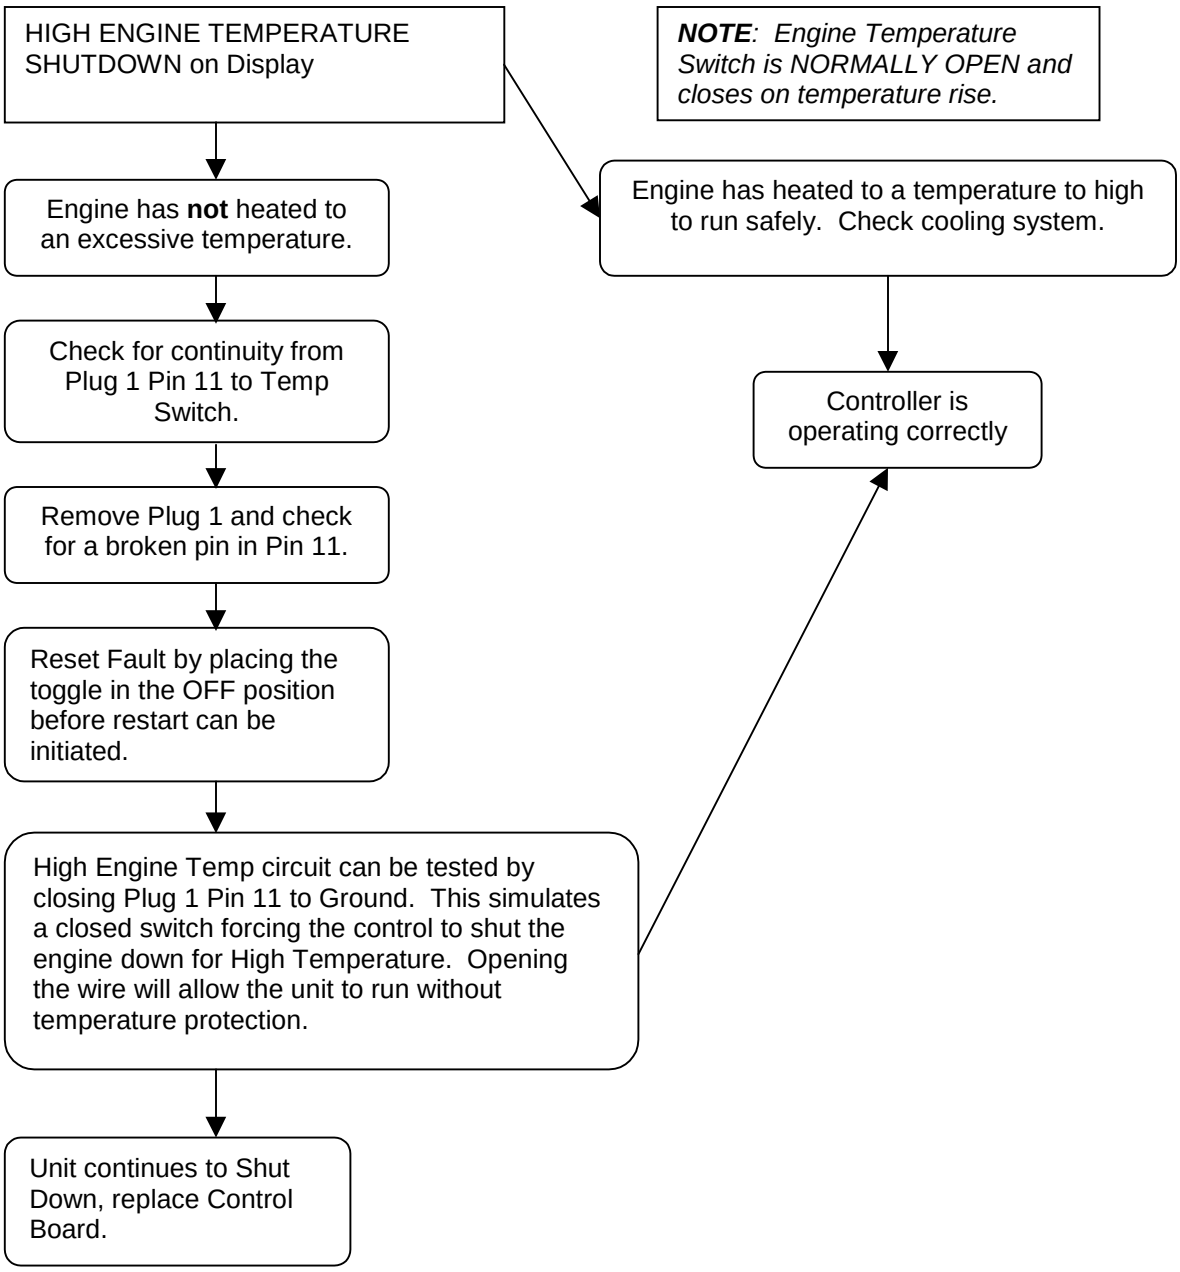
FAULT CONDITIONS

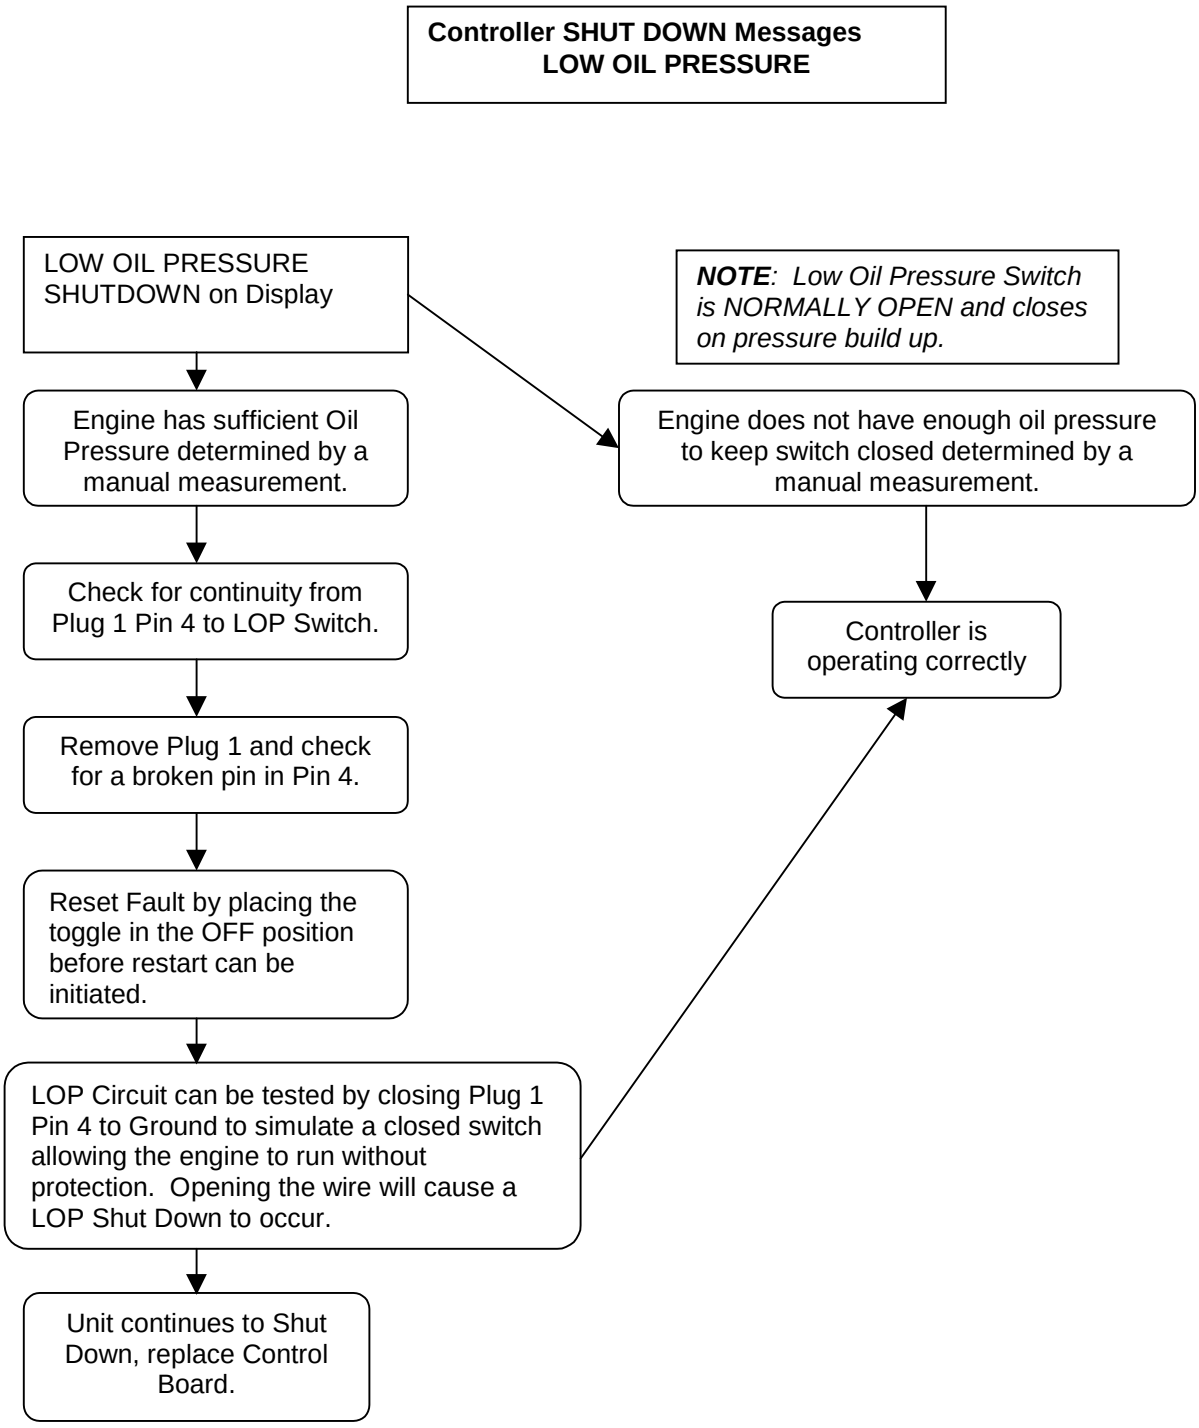
There are several features built into the Lighthouse system that will cause a shut down of the engine in the event of an abnormal operating condition. Under these conditions, the fault light illuminates and the specific fault is displayed until the controller is manually reset. LOW OIL PRESSURE. If the engine oil pressure falls below a preset level a switch activates and shuts the engine off. The fault light on the control panel will illuminate. Verify correct oil level, then reset controller by moving the Mode switch to OFF position. ENGINE OVERSPEED: If the generator frequency reaches 66HZ the controller signals the engine to shut down and the fault light will illuminate. Reset controller by moving Mode switch to OFF position, then back to desired operating mode. HIGH COOLANT TEMPERATURE SHUTDOWN: If the engine coolant exceeds 230°F the engine will automatically shut down. The fault light on the control panel will illuminate. Check coolant level and/or clear any cooling passage obstructions. Reset controller by moving Mode switch to OFF position, then back to desired operating Mode. OVERCRANK: If the generator completes five, 10 second on/10 second off crank cycles without starting an overcrank error occurs. The fault light on the control panel will illuminate. Correct the starting problem, and reset the controller by moving the Mode switch to the OFF position. Return the controller to the desired operation mode by moving the Mode switch to the appropriate position.

UNIT OPERATION TROUBLESHOOTING

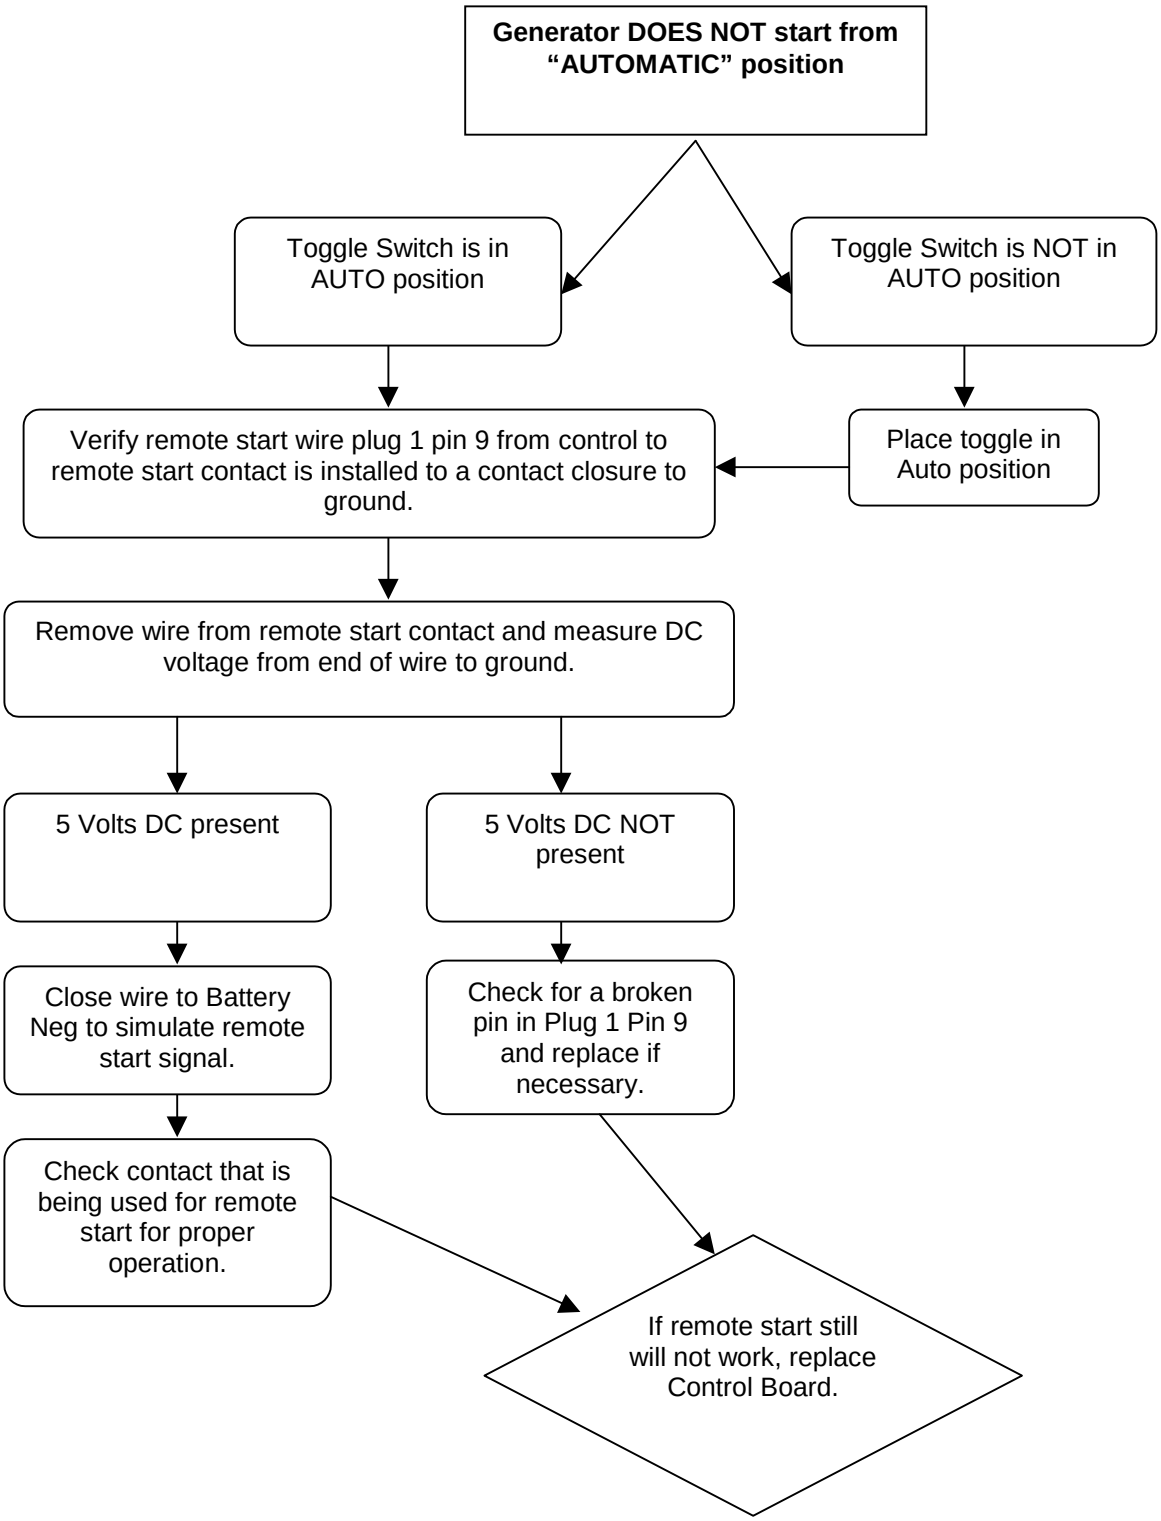
SYMPTOM	POSSIBLE CAUSE	CORRECTIVE ACTION
Engine will not crank in Manual mode.	1. Defective battery.	Recharge or replace battery.
	2. Blown control panel fuse.	Replace fuse.
	2. Loose or dirty connections.	Check and clean D.C. connections.
	3. Defective crank relay.	Replace crank relay.
	4. Defective starter.	Replace starter.
	5. Defective control.	Replace control.
Engine will crank in Manual mode, but will not start.	1. No fuel.	Check fuel supply and manual operated fuel valves.
	2. Defective controller.	Check connections, replace.
	3. Defective fuel solenoid.	Replace fuel solenoid.
	4. Problem with engine ignition system.	Test and replace.
Engine runs, but no A.C. output from the generator.	1. Main circuit breaker tripped.	Reset breaker.
	2. Defective generator.	Test and replace defective part.
	3. Improper output connections.	Reconnect properly.
Fault light on, engine will not start.	1. Low oil pressure.	Check oil level.
	2. High coolant temperature.	Allow unit to cool.
	3. Overcrank error.	Check fuel and ignition systems. Check battery and connections.
Engine starts, but shuts down immediately.	1. Low oil pressure.	Check oil level.
	2. Low fuel pressure.	Check fuel supply, pipe size.
	3. Defective controller.	Replace controller.
Battery will not stay charged.	1. Defective battery.	Replace battery.
	2. Defective connections.	Clean and tighten connections.
	3. Defective alternator.	Replace alternator
	4. Defective battery charger.	Replace battery charger.
Engine will not run at full speed, or runs rough.	1. Insufficient fuel volume.	Check fuel line. Replace fuel regulator. Check regulator vent for obstructions.
	2. Engine electrical problem.	Replace spark plugs. Check ignition wiring.
	3. Engine configured for wrong fuel.	Check fuel select switch and regulator orientation.
	4. Generator over loaded.	Reduce load.

Controller SHUT DOWN Messages
HIGH ENGINE TEMPERATURE

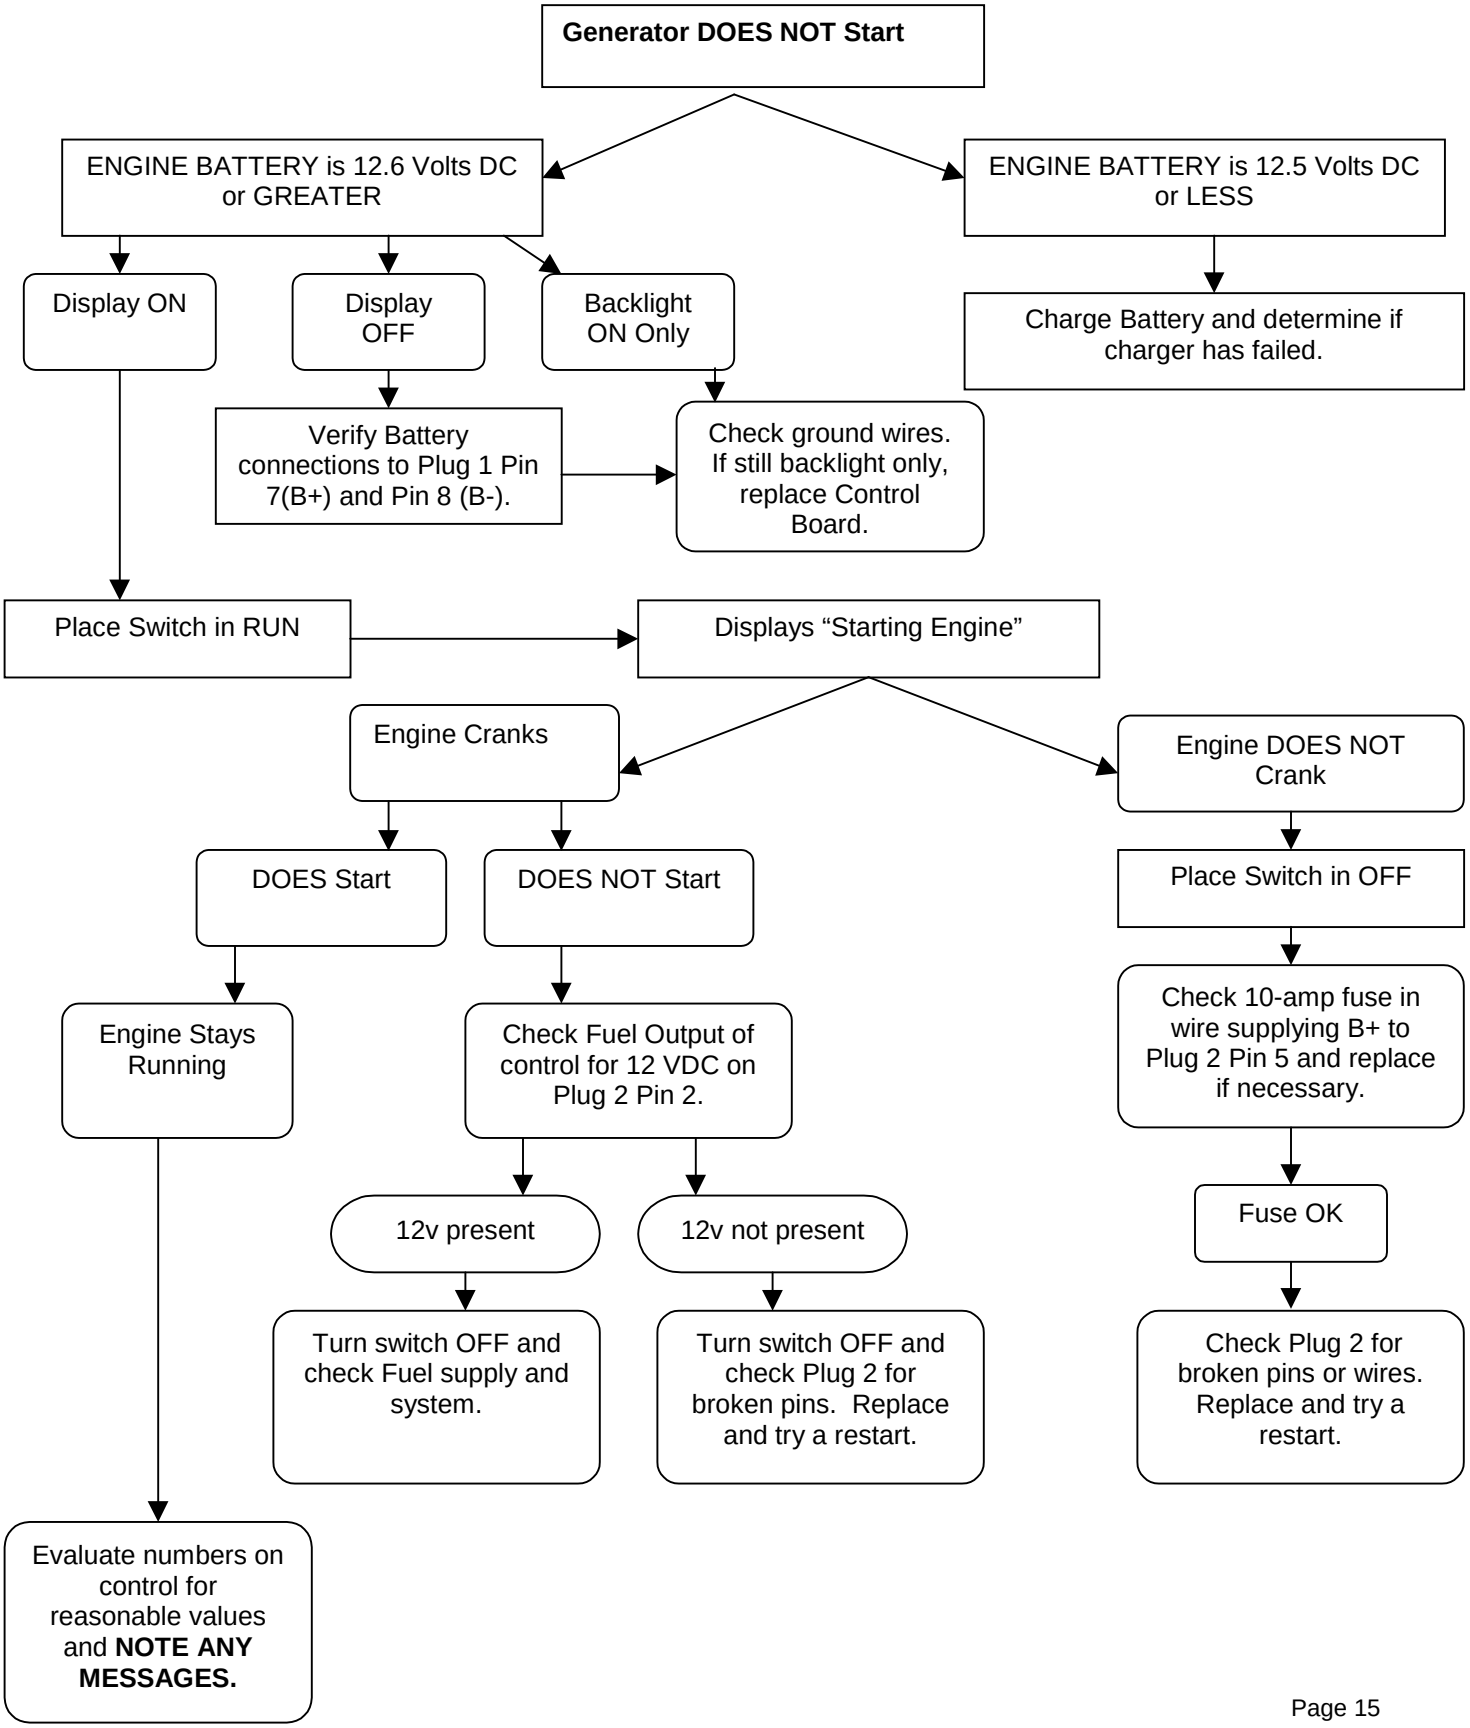




Controller SHUT DOWN Messages
LOW OIL PRESSURE
LOW OIL PRESSURE SHUTDOWN on Display
NOTE: Low Oil Pressure Switch is NORMALLY OPEN and closes on pressure build up.
Engine has sufficient Oil Pressure determined by a manual measurement.
Engine does not have enough oil pressure to keep switch closed determined by a manual measurement.
Check for continuity from Plug 1 Pin 4 to LOP Switch.
Controller is operating correctly
Remove Plug 1 and check for a broken pin in Pin 4.
Reset Fault by placing the toggle in the OFF position before restart can be initiated.
LOP Circuit can be tested by closing Plug 1 Pin 4 to Ground to simulate a closed switch allowing the engine to run without protection. Opening the wire will cause a LOP Shut Down to occur.
Unit continues to Shut Down, replace Control Board.

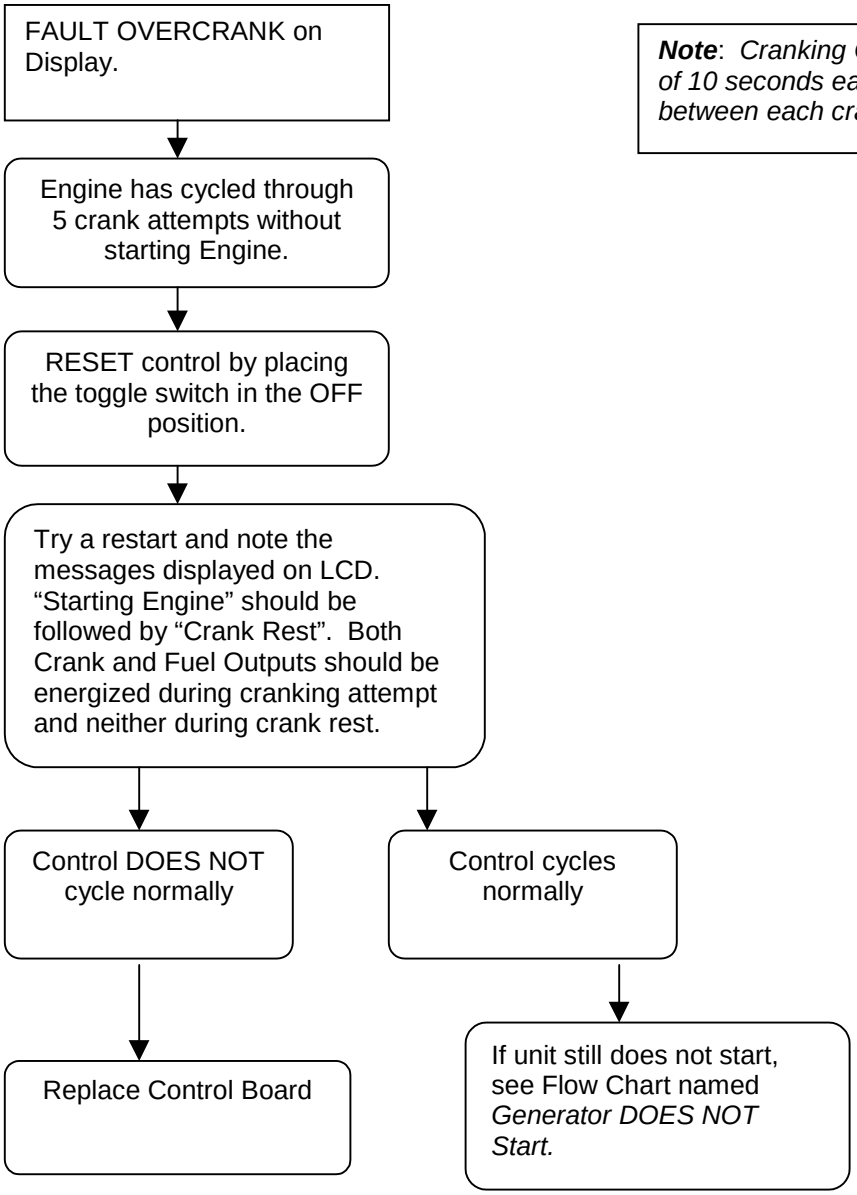


Generator DOES NOT start from "AUTOMATIC" position
Toggle Switch is in AUTO position
Toggle Switch is NOT in AUTO position
Verify remote start wire plug 1 pin 9 from control to remote start contact is installed to a contact closure to ground.
Place toggle in Auto position
Remove wire from remote start contact and measure DC voltage from end of wire to ground.
5 Volts DC present
5 Volts DC NOT present
Close wire to Battery Neg to simulate remote start signal.
Check for a broken pin in Plug 1 Pin 9 and replace if necessary.
Check contact that is being used for remote start for proper operation.
If remote start still will not work, replace Control Board.

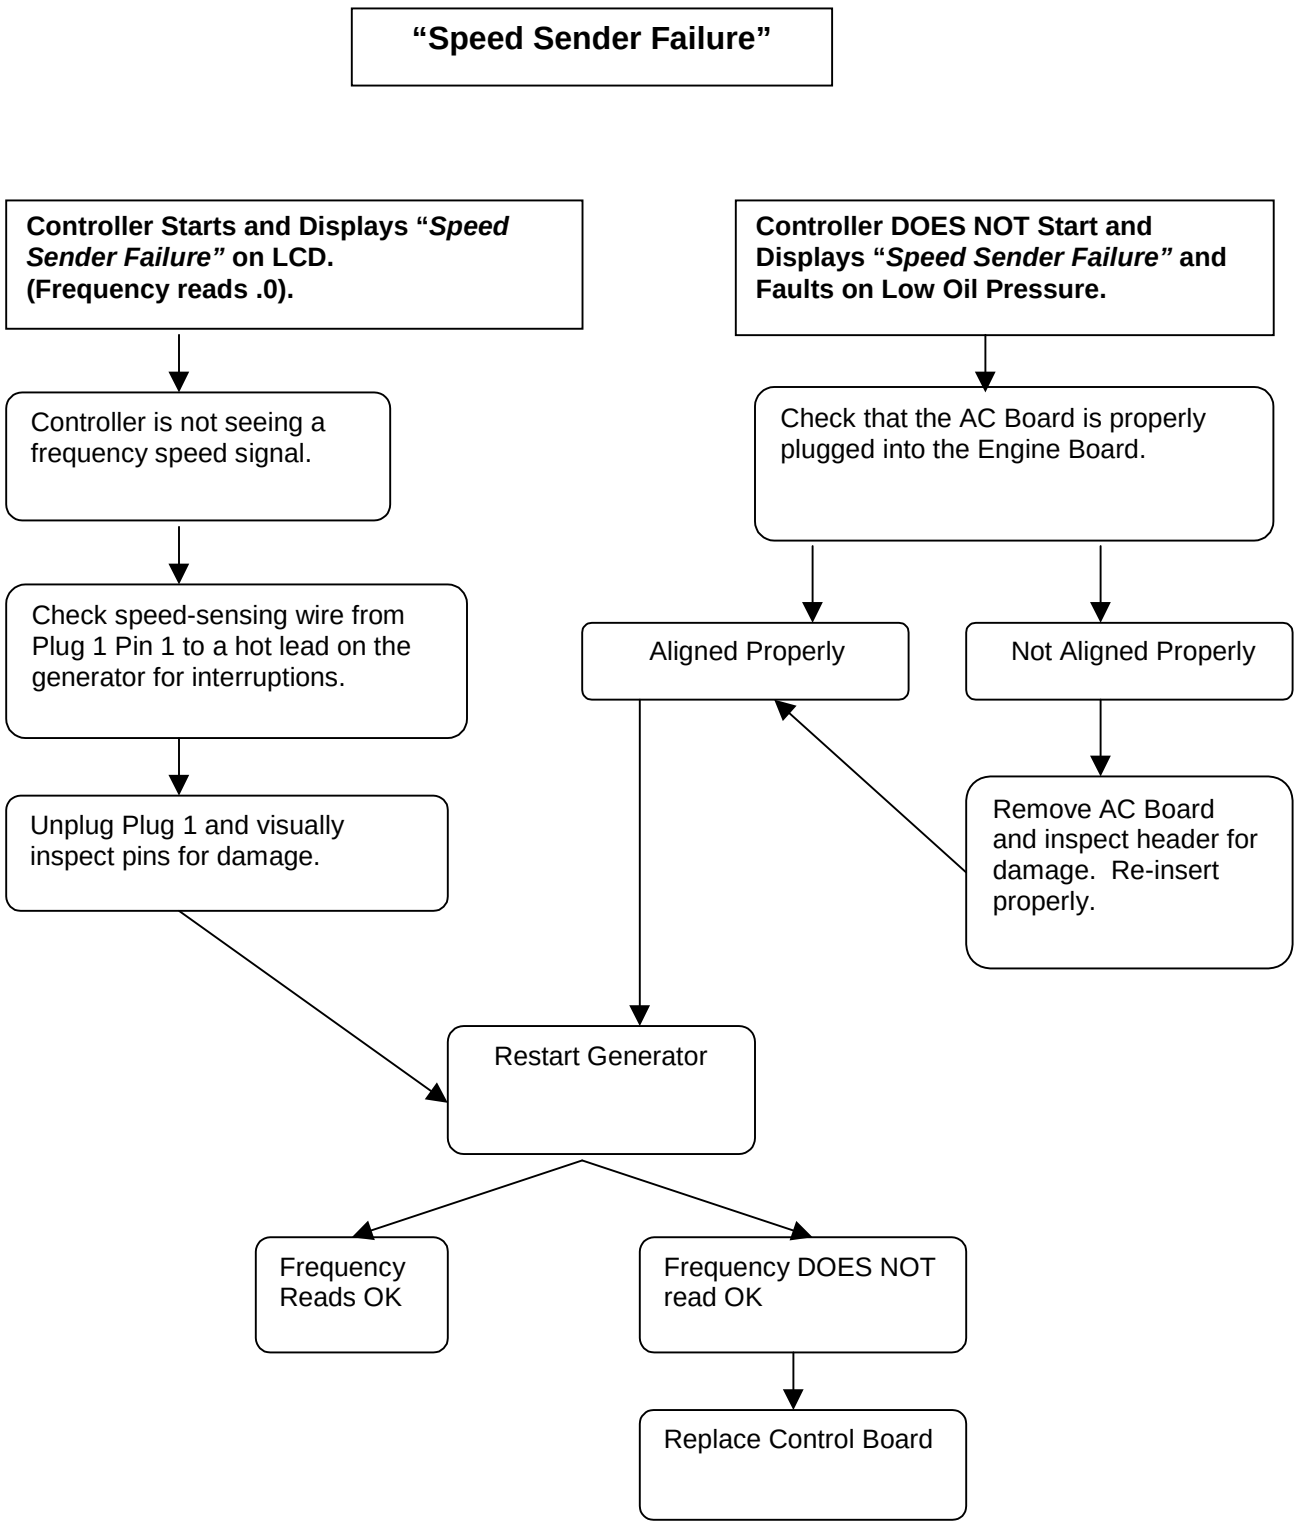


Generator DOES NOT Start
ENGINE BATTERY is 12.6 Volts DC or GREATER
ENGINE BATTERY is 12.5 Volts DC or LESS
Display ON
Display OFF
Backlight ON Only
Charge Battery and determine if charger has failed.
Verify Battery connections to Plug 1 Pin 7(B+) and Pin 8 (B-).
Check ground wires. If still backlight only, replace Control Board.
Place Switch in RUN
Displays “Starting Engine”
Engine Cranks
Engine DOES NOT Crank
DOES Start
DOES NOT Start
Place Switch in OFF
Engine Stays Running
Check Fuel Output of control for 12 VDC on Plug 2 Pin 2.
Check 10-amp fuse in wire supplying B+ to Plug 2 Pin 5 and replace if necessary.
12v present
12v not present
Fuse OK
Turn switch OFF and check Fuel supply and system.
Turn switch OFF and check Plug 2 for broken pins. Replace and try a restart.
Check Plug 2 for broken pins or wires. Replace and try a restart.
Evaluate numbers on control for reasonable values and NOTE ANY MESSAGES.

Controller SHUT DOWN Messages
OVERCRANK



Note: *Cranking Cycle is 5 crank attempts of 10 seconds each with a 10-second rest between each crank cycle.*



"Speed Sender Failure"
Controller Starts and Displays "Speed Sender Failure" on LCD. (Frequency reads .0).
Controller DOES NOT Start and Displays "Speed Sender Failure" and Faults on Low Oil Pressure.
Controller is not seeing a frequency speed signal.
Check that the AC Board is properly plugged into the Engine Board.
Check speed-sensing wire from Plug 1 Pin 1 to a hot lead on the generator for interruptions.
Aligned Properly
Not Aligned Properly
Unplug Plug 1 and visually inspect pins for damage.
Remove AC Board and inspect header for damage. Re-insert properly.
Restart Generator

The purpose of this manual is to provide the user of KATO KAMAG 14 generators with the information required to install, operate and maintain the generator.

—— NOTICE ——

THROUGHOUT THIS MANUAL FREQUENCY IS EXPRESSED IN HERTZ RATHER THAN CYCLES PER SECOND (CPS).

50 Hertz = 50 CPS
60 Hertz = 60 CPS

THIS MANUAL INCLUDES BOHT ENGLISH AND METRIC SYSTEM OF MEASUREMENTS. DIMENSIONS ARE GIVEN IN INCHES AND MILLIMETERS (MM). TEMPERATURE IS GIVEN IN FARENHEIT AND CENTIGRADE AND PRESSURE IS GIVEN IN PSI AND KG/CM^2.

– CAUTION –

CONNECT LOAD LINES AND WIRES WITHIN TERMINAL BOX. THEN INSULATE AND TAPE THE CONNECTIONS BEFORE STARTING GENERATOR SET. REFER TO TABLE D PAGE 2-11 FOR APPROPRIATE ELECTRICAL CONNECTION DIAGRAM. FAILURE TO OBSERVE THIS PRECAUTION CAN RESULT IN SERIOUS ELECTRICAL SHORT CIRCUITS.

KATO KAMAG 14 SERIES GENERATORS

This manual contains installation, operation and maintenance instructions for the KAMAG 14 series brushless synchronous revolving field generators. The generators are manufactured in both a single bearing and a two bearing line. Single bearing generators are designed for direct coupling to industrial engines while two bearing generators are designed for flexible coupling or belted coupling to electrical motors or other types of prime movers.

The series is manufactured in three phase 60 hertz ratings of from 10 to 50 kilowatts. The units can be used for 50 hertz operation at 5/6 of the three phase 60 hertz rating and single phase at 2/3 of the three phase rating. A list of the standard sizes of KAMAG 14 generators is given in TABLE A on page 1-3 of this publication. The various voltages obtainable from standard KAMAG 14 generators is given in TABLE B on page 1-3 of the publication.

The KAMAG 14 generator includes brushless exctier mounted within the generator frame and a saturable transformer voltage regulator mounted within the generator outlet box. The saturable transformer voltage regulator utilizes a solid state preamplifier for voltage error detection and control and includes a series-boost circuit which increases regulator output during periods of high line current demands such as when motors are started or if a short occurs in the load. An auto voltage adjust potentiometer, which is standard on all units, permits the user to change the generator output voltage over a range of approximately ten percent below to ten percent above the nominal values given in TABLE B on page 1-3. TABLE D on page 2-11 lists the different ways the generator can be connected to obtain the various output voltages.

The KAMAG14 series has the overall dependability of KATO Engineering Company products. The brushless design and use of saturable transformer type voltage regulator eliminate all movable contacts and brushes. The absence of brushes and contacts which are subject to wear and arcing insures maximum service life with a minimum of periodic preventive maintenance and permits use in hazardous locations where electrical codes do not require explosion proof enclosures. The KAMAG 14 rotor turns on pre-packed shielded ball bearings oversized for maximum service life. No periodic replenishment of grease is required.

In general, the KAMAG 14 generator should require little maintenance other than keeping the unit clean.

For best performance and longest service life, the following procedures are especially important:

MAKE CERTAIN THE GENERATOR IS PROPERLY CONNECTED TO THE PRIME MOVER.

MAKE CERTAIN THE GENERATOR IS CORRECTLY CONNECTED FOR THE LOAD IT IS SUPPLYING.

MAKE CERTAIN THE LOAD DOES NOT EXCEED THE GENERATOR RATING.

MAKE CERTAIN SUFFICIENT COOLANT AIR IS AVAILABLE. KEEP ALL AIR PASSAGES CLEAR OF DUST AND OTHER FOREIGN MATERIAL.

MAKE CERTAIN GENERATOR SPEED IS CORRECT – FREQUENCY IS DIRECTLY PROPORTIONAL TO GENERATOR SPEED. VARIATIONS IN SPEED WILL CAUSE VARIATIONS IN OUTPUT FREQUENCY. RUN GENERATOR 1800 RPM TO PRODUCE OUTPUT FREQUENCY OF 60 HERTZ. RUN GENERATOR 1500 RPM TO PRODUCE OUTPUT FREQUENCY OF 50 HERTZ.

WARRANTY

Kato Engineering Company warrants that the apparatus manufactured by us will deliver its rated output, providing such apparatus is properly installed, properly cared for, and properly operated under normal environmental conditions.

Standard products manufactured by Kato Engineering Company are warranted to be free from defects in workmanship and material for a period of one year from the date of shipment, and any products which are defective in workmanship or material will be repaired or replaced at the option of Kato Engineering Company. Final determination as to whether a product is actually defective rests with Kato Engineering Company. The obligation of Kato Engineering Company hereunder shall be limited solely to repair and replacement at its factory, of products that fall within the foregoing limitations, and shall be conditioned upon receipt by Kato Engineering Company of written notice within the warranty period of any alleged defects or deficiency. No products shall be returned to Kato Engineering Company without its prior consent. In no case can Kato Engineering Company accept shipping charges incurred either through return of defective items to its factory or return of repaired or replacement item to the user. Kato Engineering Company cannot assume responsibility or accept invoices for unauthorized repairs to its components, even though defective. In the case of components, parts, or units purchased by Kato Engineering Company, the obligation of Kato Engineering Company shall not exceed the settlement that it is able to obtain from the supplier thereof.

The life of the products of Kato Engineering Company depends to a large extent upon type of usage thereof, and Kato Engineering Company makes no warranty as to period of service nor as to fitness of its product for specific applications by the buyer unless Kato Engineering Company specifically agrees to otherwise in writing after the proposed usage has been made known to it. In no event will Kato Engineering Company be liable for consequential or incidental damages or for any expense incurred by Buyer due to use or sale of products sold by Kato Engineering Company.

The foregoing warranty is exclusive and in lieu of all other warranties expressed or implied, including but not limited to any warranty of merchantability or of fitness for a particular purpose.

This Warranty does not apply to experimental or developmental products.

SECTION 1 INTRODUCTION & DESCRIPTION

1.1 INTRODUCTION

1.1.1 The KAMAG 14 series by Kato Engineering Co. is a complete electrical power generating system including AC generator, brushless exciter and magnetic amplifier type voltage regulator designed and built to be light enough to be easily movable, rugged enough to be durable and versatile enough to be part of any fixed installation.

1.1.2 The magnetic amplifier type voltage regulator includes such features as 2% regulation, current boost to provide short circuit current capabilities and excellent motor starting capabilities. RFI suppression to meet MIL-1-16910, ruggedness and simplicity of design.

1.1.3 The KAMAG 14 generator and voltage regulator has been designed as an electrical power generating system and therefore complete component compatibility can be assured.

1.1.4 The instruction manual has been compiled to provide receiving and inspection procedures, precautions and recommendations as to assembly to prime movers and location for operation, initial start-up and operation instuctions, and routine maintenance recommendations. With proper maintenance and operation, the KAMAG 14 generator will provide many years of trouble-free service.

1.2 KAMAG 14 ELECTRICAL POWER GENERATING SYSTEM

1.2.1 The KAMAG 14 electrical power generating system can be divided into three basic components; the AC generator, brushless exciter and static regulator. Each component has been designed and built to insure maximum simplicity and reliability without sacrificing quality and performance.

1.3 KAMAG GENERATOR

1.3.1 The KAMAG Generator in a word is versatility. Many different configurations can be supplied to aid in coupling to the prime mover. The two bearing arrangement can be used wherever it is impracticable to have the power output shaft of the prime mover support the drive end of the generator rotor. KAMAG 14 generators of two bearing design use an antifriction bearing on each end of the shaft to support the rotor assembly. The two bearing type generator can be driven through any non-weight bearing coupling such as "V" belts, rubber block, spring, etc.

1.3.2 The KAMAG Generator is also manufactured in a single bearing line where the power input end of the rotor is supported by the prime mover. The generator frame and rotor can be purchased to fit any standard SAE flywheel and flywheel housing in its size range. Adaption can also be made to several commonly used non-SAE drives. A weight bearing semiflexible laminated plate coupling is furnished with the single bearing units for direct coupling to the prime mover.

1.3.3 When the single bearing configuration is requested it will be furnished with mounting feet on the adaptor unless otherwise specified. These mounting feet will allow the generator to support the power output end of the prime mover to simplify subbase design.

1.4 KAMAG BRUSHLESS EXCITER

1.4.1 The KAMAG Brushless Exciter is a revolving armature, three phase, high frequency generator, the output is rectified by a three diode rectifier bridge mounted directly on the main generator shaft. The exciter armature is pressed into position on the main generator shaft and held in place by a square key and locking nut. The exciter stator is secured to the endbell assembly. The purpose of the exciter is to provide a rotating magnetic amplifier to supply power to the main generator field.

1.4.2 By using the brushless design, components such as slip rings, commutators, brushes, or any form of sliding contacts that wear and need periodic maintenance have been eliminated. The rectifiers used in the rectifier bridge are of a type that are self protected against failure from voltage transients.

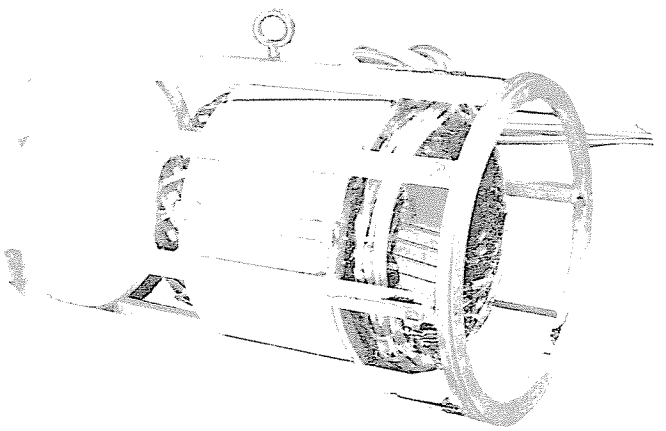

FIGURE 1-2 GENERATOR FRAME & STATOR ASSEMBLY

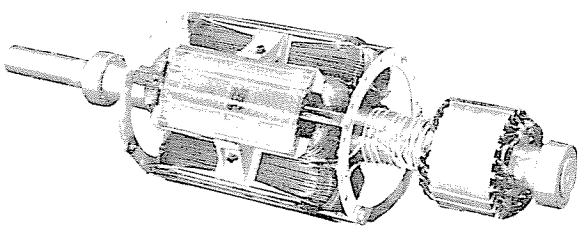

FIGURE 1-3 GENERATOR ROTOR & EXCITER ARMATURE ASSEMBLY

1.5 KAMAG VOLTAGE REGULATOR

1.5.1 The brushless generator uses a stationary exciter field to control the generator output power. The regulator provides power to the exciter field, changing field excitation automatically to maintain the generator output voltage at a near constant level regardless of changes in the load.

1.5.2 The regulator is designed to maintain the generator output voltage within 2% of the pre-set value, from no load to full rated KW and is capable of providing more than 200% rated short circuit current for motor starting loads. The regulator obtains its power from the generator output voltage and the generator output current.

1.5.3 The regulator is of the magnetic amplifier type. A highly reliable saturable transformer and solid state pre-amplifier are used.

1.5.4 The KAMAG voltage regulator consists of four basic circuits:

1) Sensing and differential detector
2) Differential preamplifier
3) Saturable transformer
   (basically a magnetic amplifier)
4) Output rectifier bridge

The first two circuits are incorporated on a rugged printed circuit board that is securely mounted to the regulator base plate. The components are mounted on the printed circuit board and are epoxied to the board to prevent movement under vibration from the operation of the unit. The saturable transformer is mounted on the voltage regulator base plate. The regulator base plate is a rigid formed steel plate with provision for three point mounting in the outlet box.

1.5.5 The regulator is designed so that the generator voltage and current add vectorially in a saturable transformer TS-1 to provide the field excitation necessary to maintain the generator output within the regulation band. A dc control winding on the saturable transformer is able to control the output of the secondary of the transformer.

1.5.6 A transistor amplifier senses the generator voltage, compares it with a reference voltage, and causes the dc control current to respond to varying load conditions. Increasing control current causes a reduction in generator voltage and a decrease in control current causes an increase in generator voltage.

1.5.7 The saturable transformer TS-1 and linear reactor L1 are designed to match the generator open-circuit exciter field characteristics. The current boost is designed to match load conditions.

1.5.8 In order to provide voltage range adjustments and compensate for temperature variations, the dc control winding provides control over the maximum flux density in the saturable transformer and therefore the maximum voltage output that the transformer will support.

1.5.9 The output of the saturable transformer is rectified and fed to the exciter field. Thus, the generator terminal voltage is maintained at the pre-set level by controlling the regulator output. The setting of the voltage adjust potentiometer and voltage range adjust potentiometer determines the pre-set level. Adjusting the voltage adjust potentiometer allows an adjustment of the generator voltage.

1.5.10 Since the dc control winding consists of a large number of turns and the flux density depends on ampere-turns the control current can be in the order of milliamperes. The resultant current gain allows the use of a transistor pre-amplifier for close regulation.

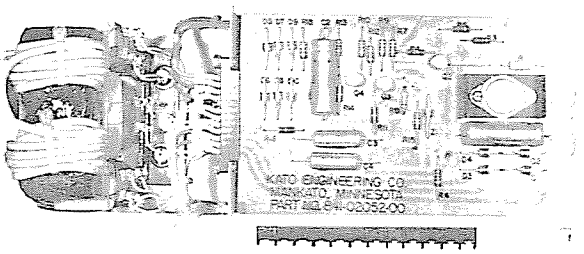

FIGURE 1-4 KAMAG STATIC REGULATOR ASSEMBLY

1.6 POWER RATINGS

1.6.1 The KAMAG 14 generator is manufactured utilizing a three phase stator winding. Twelve leads are connected to the stator windings and brought out to the outlet box at the end of the generator. By making the proper connection, this feature permits use of the KAMAG 14 generator to supply common three phase and single phase voltages. The units will also operate at either 60 hertz or 50 hertz.

1.6.2. TABLE A, page 1-3 lists the standard sizes of KAMAG 14 generator, gives the three phase, 60 hertz rating and also gives the comparative rating for 50 hertz and single phase operation. TABLE B, page 1-3 lists the various voltages obtainable from the KAMAG 14 generator when the appropriate connections are made. A voltage adjust rheostat provides a means of obtaining additional changes in voltage. It permits a voltage change over a range of approximately ten percent below to ten percent above the values given in TABLE B. TABLE D, page 2-11 lists the connections that must be made to obtain the desired voltage. The various connections are shown in figures 2-16 through 2-21, pages 2-12 through 2-14.

1.6.3. The standard KAMAG 14 generator is manufactured with a three phase, 60 hertz temperature rise rating of 70° centigrade.

The following conditions apply to all standard KAMAG 14 generators:

1. All units capable of 50 hertz operation at 5/6ths of the 60 hertz voltage and KVA.

2. All three phase units reconnectable to single phase at 2/3 rating. All single phase units reconnectable to three phase at 3/2 single phase rating.

3. All standard KAMAG 14 generators are rated 70° C temperature rise for three phase operation. When connected single phase, the temperature rise will be 90° C.

4. Three phase units have overload capacity of ten percent NEMA standby. No overload capabilities are offered when connected single phase.

5. By turning the voltage adjust potentiometer, the operator of KAMAG 14 generators can obtain output voltage over a range of approximately ten percent lower to ten percent higher than the nominal values given in TABLE B.

1.7 THEORY OF OPERATION

1.7.1 The generator output voltage is produced in the generator stationary armature (stator). Voltage is induced into the stator windings by a rotating magnetic field produced by the turning generator field.

1.7.2 In order for the generator field to become magnetized and produce a rotating magnetic field, a dc voltage (excitation) must be fed to the generator field coils and the generator rotor must be turning.

1.7.3 The excitation voltage is supplied by the exciter. The exciter field poles retain some permanent magnetism thus producing a magnetic field in the exciter. When the generator is started, voltage is induced in the exciter armature windings, fed to the rotating rectifiers, rectified and fed to the generator field. The generator field then becomes magnetized and produces a rotating magnetic field. Control of the degree of magnetism of the generator field and thus the voltage induced into the generator stator windings is dependent on the voltage it is supplied by the exciter. This is controlled by regulating the exciter field by controlling the field current fed to the exciter. The voltage regulator supplies and controls the field current fed to the exciter field.

TABLE A POWER RATINGS OF KAMAG 14 GENERATORS

MANUFACTURER'S CODE	3 PHASE 60 HERTZ		3 PHASE 50 HERTZ		SINGLE PHASE 60 HERTZ		SINGLE PHASE 50 HERTZ	
	KW	KVA	KW	KVA	KW	KVA	KW	KVA
4P1-0300	10	12.5	8.33	10.42	6.67	8.33	5.55	6.95
4P1-0300	15	18.75	12.50	15.63	10	12.5	8.33	10.42
4P1-0400	20	25.0	16.67	20.83	13.33	16.67	11.11	13.89
4P1-0600	30	37.5	25	31.25	20	25	16.67	20.83

TABLE B FREQUENCY AND VOLTAGE RATING OF KAMAG 14 GENERATORS

RPM	HERTZ	VOLTAGE	
		3 PHASE	SINGLE PHASE
1800	60	120/208 - 139/240 240/416 - 277/480	120/240
1500	50	100/173 - 115/200 200/346 - 230/400	115/230

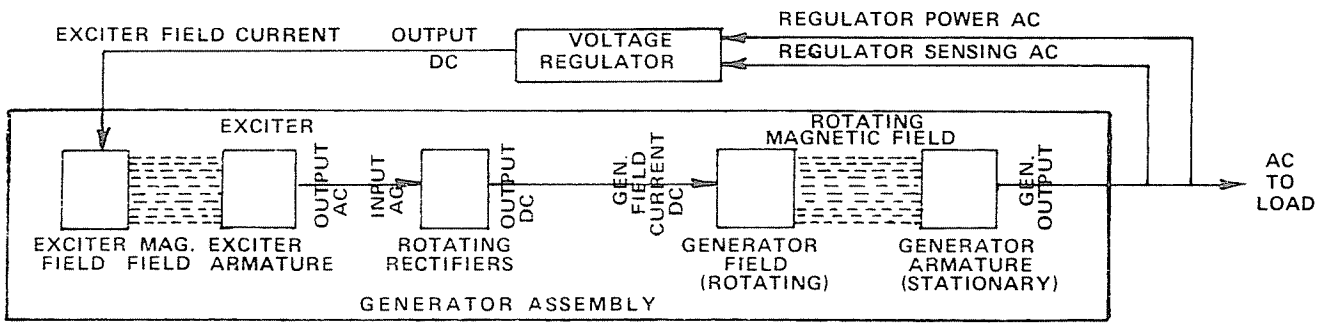

FIGURE 1-5 BLOCK DIAGRAM KAMAG 14 ELECTRICAL POWER GENERATING SYSTEM

SECTION 2 INSTALLATION

2.1 RECEIVING INSPECTION

2.1.1 The KAMAG 14 generator is carefully packed and crated for shipment, and can withstand most shocks incurred during transit. Before accepting shipment from the transportation company examine the crating carefully to determine if any damage has occurred during shipment. Unpack the unit as described in paragraph 2.2 and then carefully examine the sheet metal frame and exciter cover for signs of damage. Remove terminal box cover and examine the inside of the terminal box for signs of damage to wiring and components. Inspect for loosely mounted components and the presence of moisture. Inspect to make certain foreign material such as crating nails, loose bolts or packing material which may have fallen into the machine during unpacking are removed. On two-bearing machine turn the rotor by hand to make certain it rotates freely without binding. If damage is noted, determine the extent of damage and immediately notify the transportation company claims office and KATO Engineering Company. Be sure to give complete and accurate details when reporting damage.

2.1.2 If the generator is to be placed in storage repackage and crate the generator set. Recommended procedures for storage are contained in paragraph 2.2.

2.2 UNPACKING AND STORAGE

2.2.1 If the generator is received during cold weather, let the crated unit slowly warm to room temperature before removing the protective crating and packing material. This precaution will minimize the condensation of moisture on coil surfaces, eliminating the possibilities of wet windings and insulating materials which could cause early malfunctions of the generator.

2.2.2 Unpack the generator with care to avoid damage to the unit. Move the generator to the mounting location by attaching an overhead hoist to the eye-bolts installed in the generator frame. Determine that the hoist, when used, is of sufficient strength to adequately support the weight of the generator. Hoist and hoist cables should have a rating of not less than 1½ times the weight of the generator.

CAUTION

ALWAYS MAKE CERTAIN EXTREME CARE IS TAKEN WHEN MOVING THE GENERATOR TO PREVENT ITS STRIKING OTHER OBJECTS OR PERSONNEL. NEVER APPLY A LIFTING FORCE TO STRUCTURAL POINTS OTHER THAN THE LIFTING EYELETS.

2.2.3 If the generator is not to be installed in its operating location as soon as received, it should be stored in a clean, dry area, not subject to sudden temperature or humidity changes. If possible, storage should be in an ambient temperature of approximately normal room temperature. Units which cannot be stored in a temperature and humidity controlled area and which are to be in storage for a period of longer than six months should be prepared for storage as follows:

a. Install desiccant bags under the generator cover and inside the terminal box and vacuum seal the unit in a covering of polyethelene.

b. Adequately tag the unit to ensure that desiccant bags are removed before the generator is placed in operation.

2.3 LOCATION

2.3.1 The KAMAG 14 series generator can be installed in any well ventilated area which affords sufficient accessibility for operation and maintenance of the unit and allows a sufficient unobstructed flow of coolant air. Avoid locations which subject the generator to excessive moisture, dust, steam or the fumes from acids, alkalines or other corrosive chemicals. If such exposure cannot be avoided, establish a rigidperiodic preventive maintenance schedule. The adverse effect of excessive moisture can usually be eliminated or at least greatly lessened by the use of space or strip heaters. If the generator windings have become wet, check winding insulation resistance and if low, dry windings before operating generator. Refer to paragraphs 4.5 and 4.6.

2.3.2 The foundation or supports which mount the generator and prime mover must be rigid, level and of ample size and strength to support the weight of the generator and prime mover. Although a reinforced concrete foundation usually makes the best foundation for heavy machinery, the generator and prime mover may be placed on any concrete, steel or other structural material which will adequately support the weight of the unit. Bearing loads of structural materials can be obtained by referring to engineering handbooks.

2.4 MOUNTING SINGLE BEARING GENERATORS

2.4.1 The generator can be mounted on an extension of the engine base or on a separate foundation which is properly aligned and level with the engine foundation. Install shims between the generator base and the mounting surface as necessary to level and properly align the generator with the prime mover.

2.5 COUPLING & ALIGNMENT OF GENERATOR WITH DISK COUPLING AND ENGINE ADAPTOR

2.5.1 The disk coupling consists of several steel disks which are securely bolted to the generator rotor and to the engine flywheel. Because close tolerances are maintained in the manufacture of the engine components, generator frame and drive disks, the only alignment procedures which should normally be required are to make certain the rotor shaft and the engine flywheel are properly aligned and that the generator bearing has a nominal endclearance of: Total engine crankshaft axial movement plus 1/16 inch (1.588 millimeter). To insure proper alignment check the dimensions listed in the following steps.

NOTE: Clean accumulations of dirt or grease from mounting surfaces before checking dimensions or assembling the generator to the engine.

1. Remove generator wrapper cover and terminal box cover.

2. Check generator bearing endclearance and alignment of exciter field and exciter armature. Dimension a' ,figure 2-1 should compare with dimension given in instruction INS-2-70A supplied with generator. Exciter field and exciter armature should be aligned horizontally.

3. Check the distance from the engine bell housing mounting surface and the drive disk recess (dimension C, figure 2-2) and check the distance from the generator endring mounting surface to the outside surface of the drive disks (dimension "Y" figure 2-2). Dimension "Y" should equal dimension "C".

NOTE: The generator rotor shaft should be parallel with the generator frame when checking dimension "Y".

If "C" is more than "Y" install additional spacers between the generator drive hub and the drive disks.

NOTE: An additional spacer is normally supplied with generator.

If "Y" is more than "C" remove spacers from between the generator drive hub and drive disks.

4. Check the diameter of the drive disks and the flywheel drive disk recess, dimensions S and S , figure 2-2. If the drive disks are over or under size return them to the factory. Do not attempt to grind the drive disks.

5. Check to make certain drive disk and flywheel drive disk recess bolt hole centers are equal, dimensions B and B , figure 2-2. Return drive disks and give flywheel data if disks do not "match" flywheel dimensions. Never attempt to drill out drive disk holes.

6. With indicator base mounted on the flywheel and the indicator finger on the flywheel housing as shown in figure 2-4, turn the engine through one revolution. Maximum total indicator reading should not exceed .003 inch per foot diameter or approximately .025 millimeter per 100 millimeter diameter of the flywheel housing. See TABLE C. If runout exceeds limits, contact KATO Engineering Company and the engine manufacturer for recommendations. State flywheel housing size and runout recorded.

7. With indicator base mounted on the flywheel housing and the indicator finger on the drive disk recess as shown in figure 2-5, turn the engine through one revolution and check runout. Maximum total indicator reading should not exceed .003 inch per eachfoot diameter or approximately .025 millimeter per 100 millimeter diameter of the flywheel. Refer to TABLE C. If runout exceeds limits, contact KATO Engineering Company and the engine manufacturer and state flywheel size and runout recorded.

2.5.2 When dimensions are satisfactory, assemble the generator to the engine as described in the following steps:

NOTE: The generator is connected to the engine by inserting bolts from the generator side and tightening them into the threaded holes in the engine flywheel and flywheel housing. Bolts must be of proper length to assure adequate threading into the holes in the engine flywheel and flywheel housing.

1. Make two pilot bolts by removing heads of bolts and starting them into the holes in the engine flywheel and flywheel housing on a line across the center of the mounting surfaces as shown in figure 2-6.

2. Install lockwashers on the generator adapter endring to bell housing bolts. Install lockwashers on the drive disk to flywheel bolts.

NOTE: If there is not sufficient clearance in flywheel to permit tightening of the bolts which secure the drive disks to the flywheel, the use of spacers as shown in figure 2-9 will usually alleviate the problem.

3. Most fans are made up of two halves. This type fan can be taken apart for more working space.

NOTE: The fan was set at the factory with clearance between the fan and baffle which would provide maximum efficiency of the fan. Before loosening and moving the fan, mark position of fan on shaft. Reinstall fan to marked position approximately ½ inch or 12.7 millimeters clearance between fan and fan baffle is normal.

4. Support the generator from an overhead hoist and move the generator horizontally into place. Make certain drive disks fit completely into the drive disk recess in the flywheel.

5. Install the flywheel bolts. Tighten bolts alternately and evenly. Remove the pilot bolt and install and tighten remaining bolt.

CAUTION

Make certain bolts are not of excessive length, such that they bottom out in flywheel before they tighten against drive disks.

6. Install and tighten alternately and evenly the flywheel housing bolts. See figure 2-7. Remove the pilot bolt and install the remaining bolt.

CAUTION

Make certain bolts do not bottom out before they securely hold generator adapter against the flywheel housing.

7. Retighten each bolt completely around the mounting of both the disk coupling and generator adapter.

8. Use a feeler gage to see if there is a gap between the generator mounting feet and the generator mounting base. Add shims as necessary between the generator mounting feet and the base and then bolt the generator to the base.

9. If space permits, attach a dial indicator to the generator adapter with the dial indicator point on the generator shaft as shown in figure 2-8. Turn the engine through one revolution. Maximum total indicator reading should not exceed .005 inch or .127 millimeter.

NOTE: FAN MUST BE MOVED TO PERMIT ACCESS TO DIAL INDICATOR.

10. When alignment checks are satisfactory, reposition and tighten fan.

NOTE: Install fan to its original position on shaft. This should have been indicated by marking the shaft before moving or removing fan. Fan should be between ¼ and ½ inch or 6.35 and 12.7 millimeter from baffle when properly positioned.

2.5.3 After coupling and alignment of the generator and engine is complete but before placing generator set in operation, check clearance between generator stationary and rotating parts, especially the exciter field and exciter armature. Replace all covers and guards before placing generator set in operation.

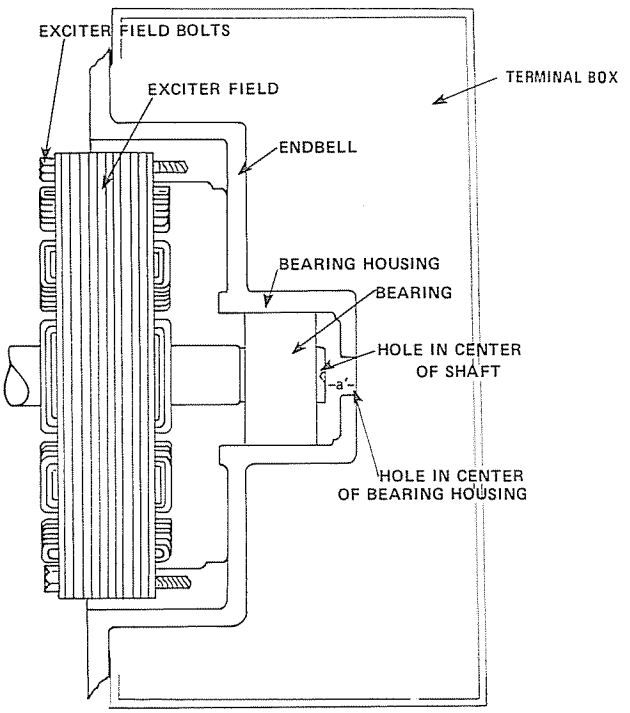

FIGURE 2-1 CHECKING BEARING END CLEARANCE
Refer to Instruction INS-2-70A supplied with the generator.

2.6 MOUNTING TWO BEARING GENERATORS

2.6.1 Two-bearing belt driven generators can be mounted on an extension of the prime mover base or on a separate foundation. Two-bearing generators which are connected to the prime mover by solid or flexible couplings or gear drives must be mounted on a rigid base. This base must provide mounting for both the generator and prime mover. The base must be placed on a level foundation and secured in place before the prime mover and generator are aligned. Refer to paragraphs 2.7 through 2.16.

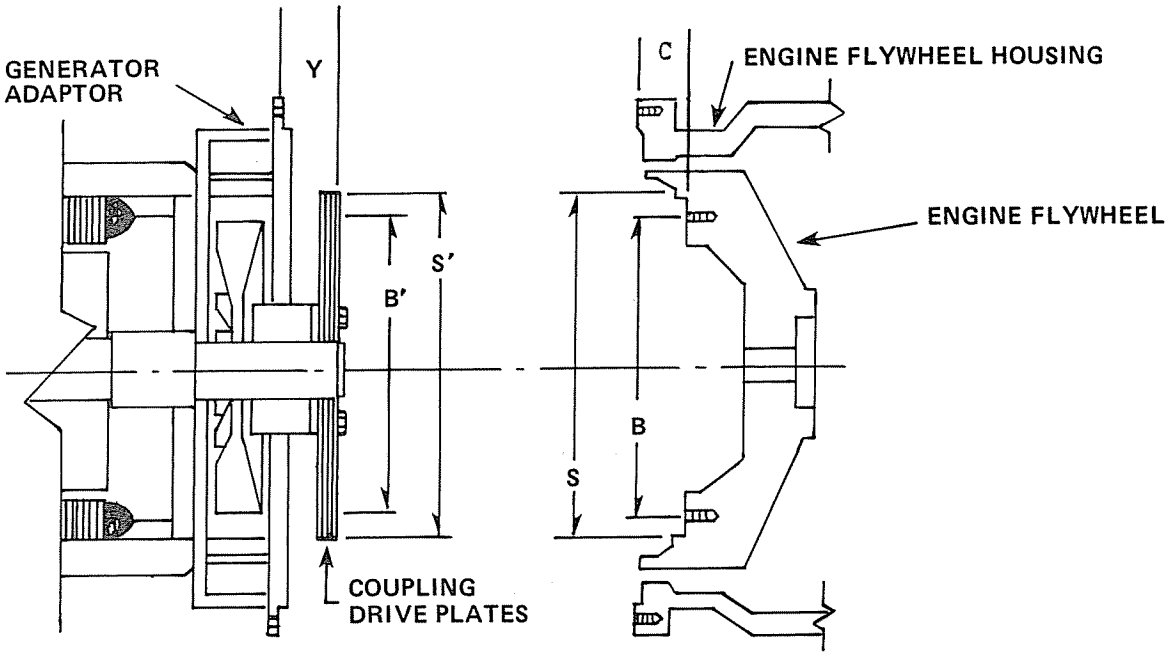

FIGURE 2-2 ENGINE AND GENERATOR COUPLING DIMENSIONS

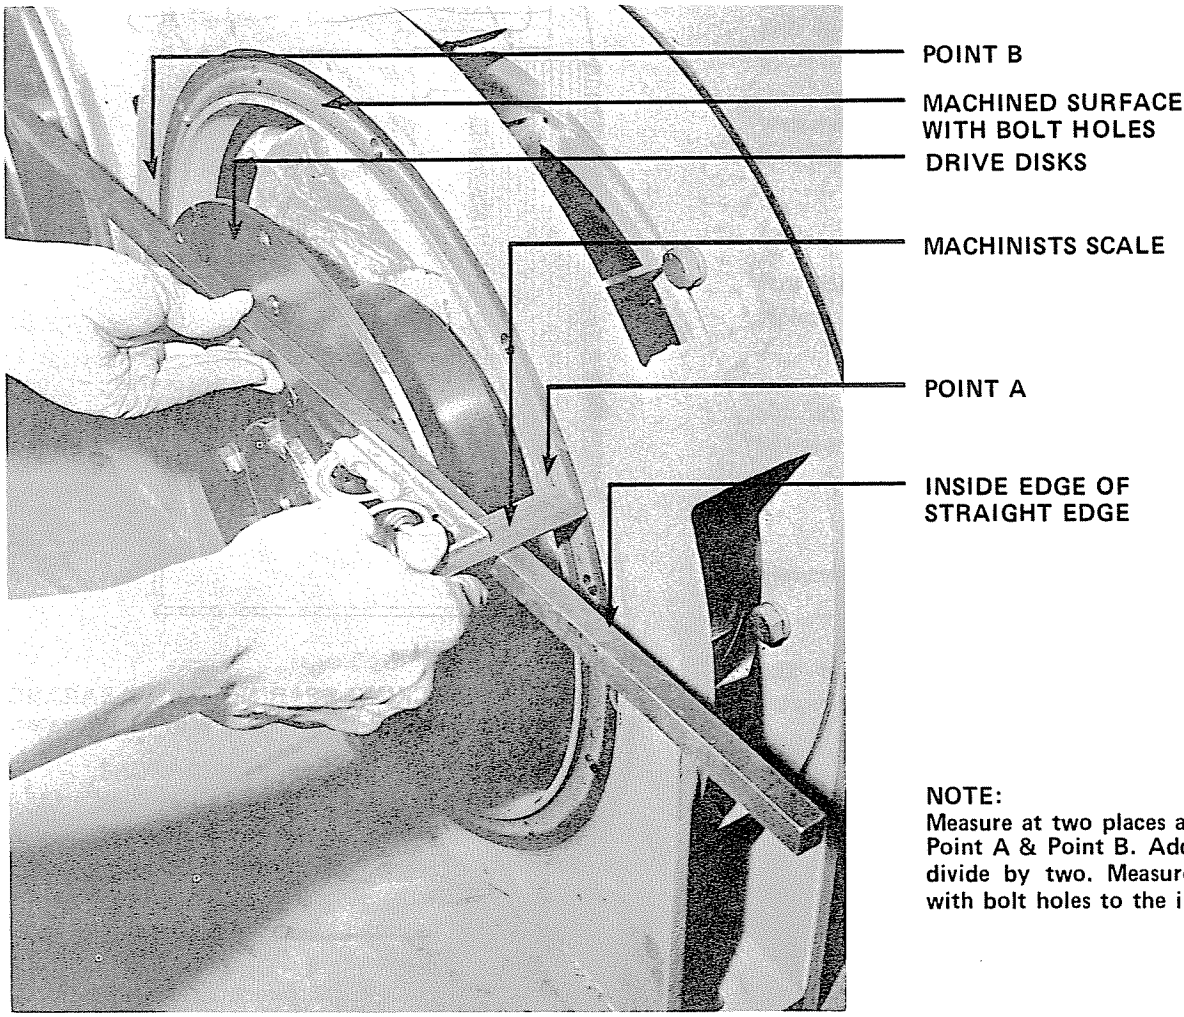

NOTE:
Measure at two places approximately 180° apart. Point A & Point B. Add the two dimensions and divide by two. Measure from machined surface with bolt holes to the inside edge of straight edge.

FIGURE 2-3 MEASURING DISTANCE FROM GENERATOR ADAPTER TO DRIVE DISKS, DIMENSION "Y"

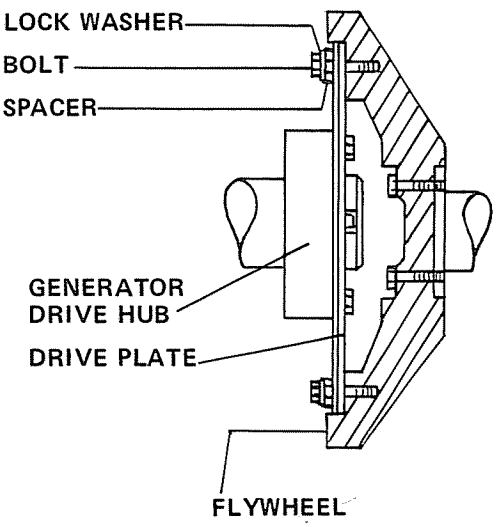

FIGURE 2-9 CROSS-SECTIONAL VIEW - DRIVE DISKS AND FLYWHEEL

2.7 SELECTION OF DRIVES FOR TWO BEARING GENERATORS

2.7.1 Satisfactory generator operation will depend upon careful selection of drive couplings. In general, solid couplings are not recommended except when the generator and prime mover frames are directly connected and belt drives should not be used when belt speed exceeds 5000 feet per minute or 1524 meters per minute.

2.8 BELT DRIVES - GENERAL INFORMATION

2.8.1 Proper alignment and tightness of belt drives is essential. Improper alignment and belt tightness will increase belt wear as well as increase bearing loads and vibration. Select belt drive in accordance with belt manufacturer's specifications. Make certain generator and prime mover are rigidly mounted.

2.9 V - BELT

2.9.1 Use only matched belt sets and avoid minimum pitch sheaves and belts. Follow the V-belt manufacturer's specifications or NEMA limits for sheave pitch.

2.9.2 Make certain the shaft axis of the prime mover and generator are parallel. Belts must enter and leave sheaves with no side bending. Tighten just enough to prevent slippage at full load. Never grease or use belt dressing on belts.

2.10 FLAT BELT

2.10.1 Selection of belts and pulleys of ample width will reduce amount of tension required to prevent slippage at full load. Lower belt tension reduces bearing loads and belt wear.

2.10.2 Position the pulleys so crowns are in the same plane. Make certain motors and generator shafts are paralleled. Observe belt manufacturer's or NEMA limits for pulley sizes.

2.11 GEAR BELTS (TIMING BELTS)

2.11.1 In general, installation of gearbelts will be the same as for flat belts. The following precautions should be taken when installing a gearbelt drive:

a. Gearbelts should be installed with snug fit, neither too tight or too loose. High initial tension is not necessary but when torque is unusually high a loose belt may "jump grooves". If the belt "jumps the grooves" the tension should be increased gradually until satisfactory operation is attained.

b. Be sure that shafts are parallel and pulleys are in alignment. On a long center drive, because of the tendency of the belt to run against one flange, it is sometimes advisable to offset the driven pulley to compensate.

c. On a long center drive, it is imperative that belt sag is not enough to permit teeth in the slack side to engage the teeth at the tight side.

d. It is important that both prime mover and generator are mounted rigidly to prevent variation in belt tension.

e. Although belt tension requires little attention after initial installation, provision should be made for some center distance adjustment for ease in installing and removing belt. Do not force belt over flange of pulley.

2.12 GEAR AND FLEXIBLE COUPLINGS - GENERAL INFORMATION

2.12.1 When drives of these types are used instead of belt drives the prime mover and generator shafts must be carefully aligned and following alignment, the motor and generator must be firmly mounted to a rigid base to prevent misalignment of the unit shafts during operation. Excessive misalignment may be the cause of vibration, noisy operation, excessive coupling or gear wear or premature bearing failure.

2.13 GEAR DRIVE

2.13.1 Accurate alignment and rigid mounting are essential for satisfactory operation with gear drives. Pitch diameter and width should not be outside recommended NEMA limits. Avoid use of couplings which will impose excessive thrust on bearings.

2.13.2 In all cases, gear teeth must be centered with each other. Gear faces must be parallel and correct shaft center distance maintained. Avoid engagement of teeth so deep that they will bind or deflect. Refer to National Gear Manufactures Association specifications.

2.13.3 Test for proper alignment by rotating shafts by hand. Check for backlash through at least one revolution of the shafts. Check backlash and gear face parallelism after tightening mounting bolts. Install or remove shims from under mounting feet to bring gear faces parallel.

2.14 INSTALLATION AND ALIGNMENT OF FLEXIBLE COUPLED DRIVES

2.14.1 The procedures outlined are for aligning flexible coupled drives. Follow the tolerances specified by the coupling manufacturer if they are less than described in this manual.

2.14.2 Install coupling hubs on generator and drive shafts in accordance with the installation procedures supplied by the manufacturer of the coupling. Then check for angular misalignment by scribing a reference mark on the coupling hub at the button or finger of the indicator to mark its position on the hub. Rotate both shafts simultaneously, keeping the finger or button of the indicator at the reference marks on the coupling hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to figure 2-10 for test setup.

ANGULAR MISALIGNMENT OF THE SHAFTS MUST NOT EXCEED .001 INCH FOR EACH INCH (0.01 MILLIMETER FOR EACH CENTIMETER) OF RADIUS OF THE COUPLING HUB TOTAL INDICATOR READING.

2.14.3 If angular misalignment is excessive, loosen motor and generator mounting bolts and place slotted shims under motor and generator mounting pads, as necessary, to correct alignment. Re-check alignment. Install or remove shims from under the mounting pads until aligned.

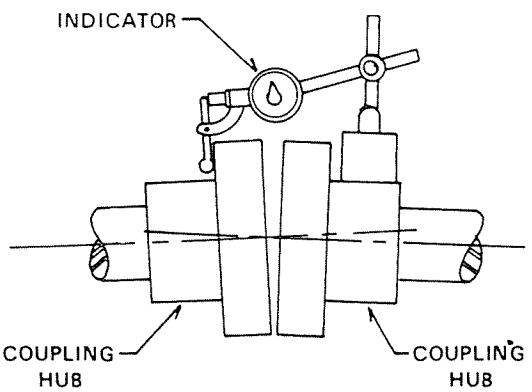

FIGURE 2-10. TESTING ANGULAR ALIGNMENT OF MOTOR AND GENERATOR SHAFTS

NOTE: If the motor generator set is moved to a new location, make test setup with coupling installed as shown in figure 2-11 and then rotate shafts and check alignment as described in paragraph 2.14.2.

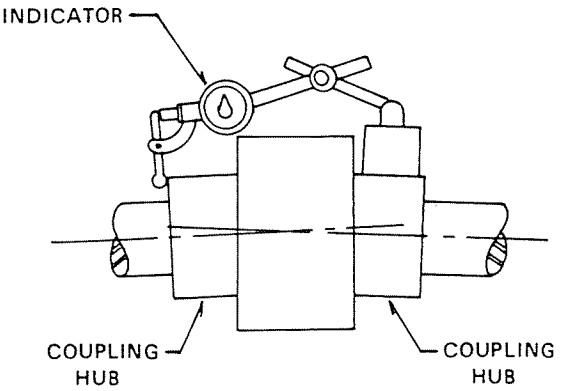

FIGURE 2-11 TESTING ANGULAR ALIGNMENT OF MOTOR & GENERATOR SHAFTS FOLLOWING COUPLING INSTALLATION

2.14.4 Check for parallel shaft (run-out) alignment by scribing a reference mark on the ground or machine diameter of the coupling hub at the finger or button of the indicator. Rotate both shafts simultaneously, keeping the button or finger of the indicator at the reference mark on the hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to figure 2-12 for test setup.

TOTAL RUN-OUT BETWEEN HUBS SHOULD NOT EXCEED .002 OF AN INCH OR .0508 MILLIMETER.

2.14.5 When run-out between hubs is excessive, install or remove shims from under each of the motor or generator mounting pads; then re-check alignment. Add or remove shims until shafts are parallel. Tighten motor and generator mounting bolts following angular and run-out alignment. Check base mounting bolts for tightness. Re-check alignment before operating unit.

NOTE: If the motor generator set is moved to a new location check for parallel alignment by making test setup as shown in figure 2-13 and then rotate shafts and check alignment as described in paragraph 2.14.4.

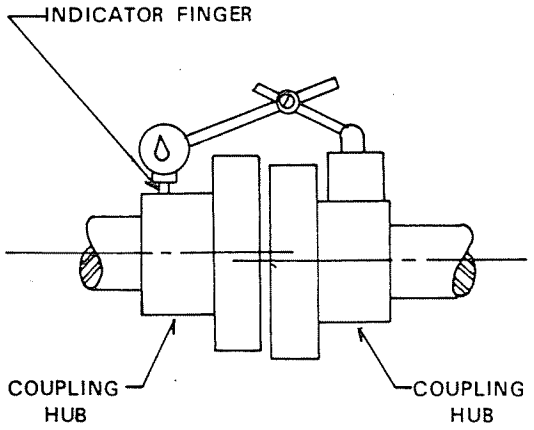

FIGURE 2-12. TESTING PARALLEL ALIGNMENT OF MOTOR AND GENERATOR SHAFTS

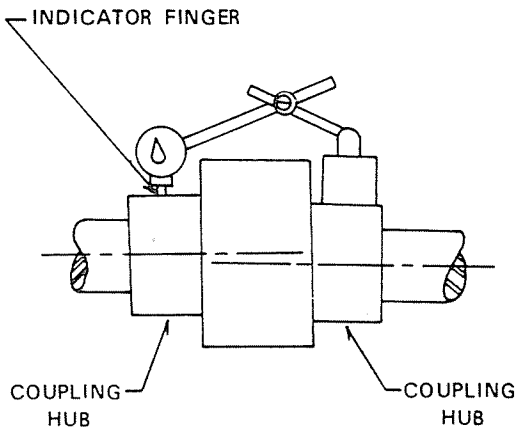

FIGURE 2-13. TESTING PARALLEL ALIGNMENT OF MOTOR AND GENERATOR SHAFTS FOLLOWING COUPLING INSTALLATION

2.15 VIBRATION

2.15.1 After alignment of motor generator set has been completed, run unit at no load and check for excessive vibration (See Operation Instructions, Section 3). If vibration is excessive loosen one motor mounting bolt slightly and if vibration decreases, add shims until retightening of bolt reduces or eliminates vibration. Repeat in turn for all motor mounting bolts.

2.15.2 When vibration and alignment of motor are within limits, run motor generator set at low load and check again for vibration. If excessive, add shims under generator mounting pads in same manner as for the motor. Re-check alignment after any change in shims to control vibration.

2.16 DOWELING

2.16.1 Doweling generator sets will prevent movement of the units during operation should the mounting bolts loosen slightly. Install dowels as follows:

a. Check the alignment after the generator set has been in operation about 40 hours. Correct alignment if not satisfactory (refer to preceding paragraphs).

b. Through opposite generator pads drill holes through and into the base. Holes should have a diameter slightly smaller than the dowel pin.

c. Ream the holes to the proper diameter for the pins, clean out chips and then install pins.

d. Repeat procedure for doweling of motor.

NOTE: Dowel prime movers (engine or motor) manufactured by others than Kato Engineering Company in accordance with the instructions supplied by the manufacturer of the prime mover.

2.17 PROTECTIVE DEVICES

2.17.1 Engine driven sets must be protected with adequate engine governors and against excessive overspeed. Refer to National Electrical Code and local electrical codes for minimum electrical requirements for the generator set. The output to the load of the KAMAG generator should always be protected with an overload protection device - circuit breaker or fuses.

2.18 ELECTRICAL CONNECTIONS

2.18.1 Before connecting the generator to the electrical power load, check nameplate for the electrical characteristics and connect the generator exactly as shown in the connection diagrams. Refer to National Electrical Code or applicable local regulations for minimum specifications for wire size, conduit and protective devices.

2.18.2 Connection Diagrams for KAMAG 14 generators are shown on figures 2-15 through 2-21. Table D shows voltages for the various connections.

2.18.3 When connecting for different voltage than the factory connection, the following connections may be left connected:

1. Leave exciter field leads F1 and F2 connected to F+ and F-.

2. Leave voltage adjust potentiometer R18 connected to terminals 7 and 8 on the voltage regulator.

3. If the unit has a separate boost transformer leave leads E and F connected.

When reconnecting for a different voltage, remove insulating tape and break connections. Reconnect as shown on appropriate drawing. Make sure all connections are securely tightened. Table D and Figures 2-15 through 2-21 show the various single and three phase connections.

CAUTION

LOOSE CONNECTIONS IN THE TERMINAL BOX CAN RESULT IN SERIOUS DAMAGE TO THE KAMAG GENERATOR AND THE EXTERNAL LOAD.

AFTER THE KAMAG GENERATOR IS RECONNECTED AND THE CONNECTIONS ARE DOUBLE CHECKED, RETAPE ALL CONNECTIONS WITH A HIGH GRADE ELECTRICAL INSULATING TAPE. ALWAYS USE NEW TAPE, DO NOT REUSE TAPE REMOVED FROM OLD CONNECTIONS.

NOTE

Close switch when generator is running lower than the rated speed of 1800 RPM, 60 HZ. or 1500 RPM, 50 HZ.

Open Idle Switch when unit is at rated speed, check voltmeter reading for correct generator output voltage and then close output circuit breaker and apply load.

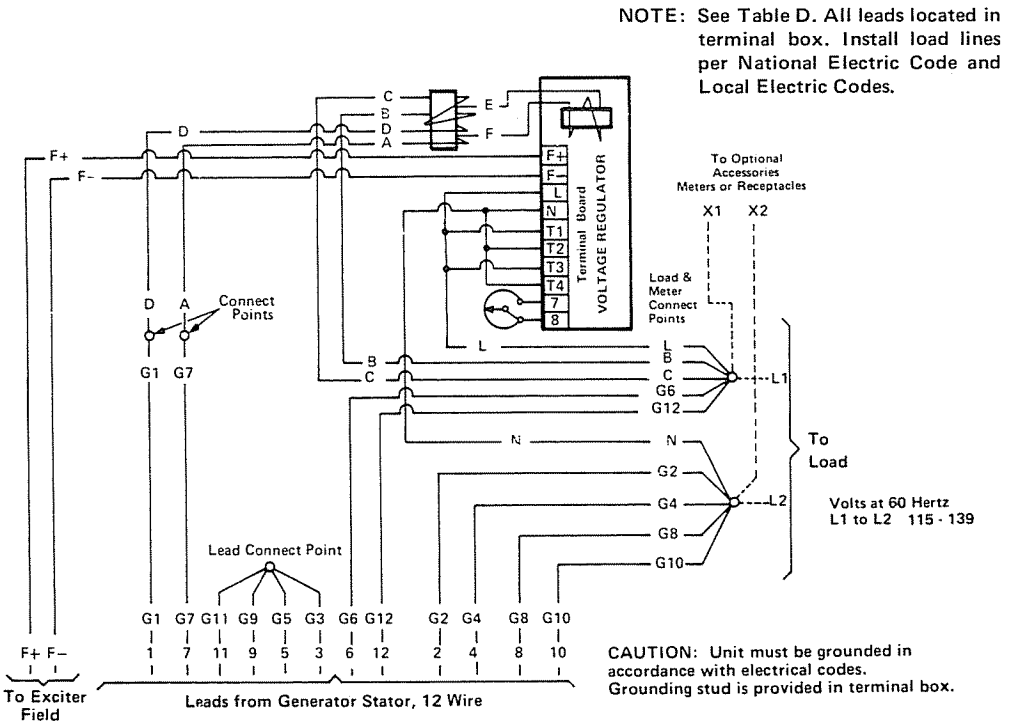

FIGURE 2-21 - ELECTRICAL CONNECTION DIAGRAM, SINGLE PHASE, TWO WIRE

SECTION 3 OPERATION

3.1 PRE-OPERATION EQUIPMENT CHECK

3.1.1 After the KAMAG 14 AC generator is completely installed and wired, but before operating the unit for the first time, perform a check of the equipement as follows:

a. If the generator has been subjected to extreme dampness during shipment or storage it may be necessary to dry out windings before placing the unit in operation. Refer to the procedures for testing winding insulation resistance and the procedures for drying windings described in Section 4 of this manual. Generators placed in operation after being subjected to very low temperatures should be slowly warmed to prevent condensation.

b. Check all interconnecting wiring against the connection diagrams. (See Section 2, Figures 2-15 through 2-21 and Table B). Make certain connections are insulated and taped.

c. Make certain no foreign objects are lodged in the generator. Remove all tools and shop clothes from the vicinity of the equipment.

d. Make certain all covers and guards are installed.

3.2 INITIAL START PROCEDURES FOR THE KAMAG 14 GENERATOR

3.2.1 After installation is complete and the checks listed in paragraph 3.1.1 have been completed, make an initial start and operational checkout of the equipment as listed in the following general instructions:

a. Open the Output Circuit Breaker to disconnect the generator from the load.

b. Turn AUTO VOLTAGE ADJUST potentiometer to maximum resistance (full counter-clockwise).

c. Start the generator set in accordance with the prime mover manufacturer's specifications. Bring up to rated speed.

NOTE: If engine idle switch is used, open switch when generator is at rated speed.

d. Stop generator set. Check rotation as unit slows to stop

e. Again start generator set and bring up to rated speed. Monitoring output voltage with a voltmeter, turn AUTO VOLTAGE ADJUST potentiometer slowly clockwise to obtain desired voltage. See figure 3-2.

NOTE: If desired voltage cannot be obtained by turning the AUTO VOLTAGE ADJUST potentiometer it may be necessary to adjust the VOLTAGE RANGE ADJUST potentiometer. Turning potentiometers clockwise increases voltage by decreasing resistance and turning potentiometers counter-clockwise decreases voltage by increasing resistance.

f. Start and stop generator set several times, observe any unusual conditions such as excessive noise or vibration. Allow sufficient time between starts for cooling.

g. Close Output Circuit Breaker and apply a light load. Adjust AUTO VOLTAGE ADJUST potentiometer to obtain desired output voltage. Slowly increase load to the generator rated power factor fully load value. Adjust AUTO VOLTAGE ADJUST potentiometer as necessary, to obtain desired output voltage.

h. Check voltage regulation. If voltage is not stable or response is slow, adjustment of the Stability Adjust resistor may be necessary. Paragraph 3.9 describes procedures for setting Stability Adjust Resistor R8.

i. During operation, observe the generator at regular intervals so that any abnormal conditions can be corrected before serious damage occurs.

j. With a steady rated power factor full load applied, check current on each line. Use clip-on ammeter if an ammeter is not incorporated in generator set.

k. Check line voltage. On three phase, phase 1 to 2, phase 2 to 3 and phase 1 to 3. On single phase: L1 to L2, L1 to N and L2 to N.

3.3 SINGLE GENERATOR OPERATION INSTRUCTIONS

3.3.1 If generator windings are wet, check winding insulation resistance and dry windings before operating generator. Refer to Section 4, Paragraphs 4.5 and 4.6.

3.3.2 Start and operate the generator set in accordance with the following general instructions:

a. Start the generator set in accordance with the operating instructions supplied by the manufacturer of the prime mover. Operate at rated speed.

NOTE: If engine idle switch is provided, open switch (set to run position) when generator is at rated speed.

b. When the AUTO VOLTAGE ADJUST potentiometer and VOLTAGE RANGE ADJUST potentiometer has been adjusted to provide the desired output voltage, no further adjustment of these devices is required prior to placing the generator set in operation. If previous voltage setting is not known, turn the AUTO VOLTAGE ADJUST potentiometer to midpoint position before placing set in operation. During operation turn AUTO VOLTAGE ADJUST potentiometer to obtain desired output voltage.

NOTE: If desired voltage cannot be obtained, the Voltage Range Adjust potentiometer may need adjustment. Turning potentiometers clockwise increases voltage and when they are turned counter-clockwise voltage will decrease.

c. Check voltage regulation with rated power factor load applied. Refer to procedures outlined in paragraph 3.2.1, if output voltage or voltage regulation is not satisfactory.

d. During operation, observe the generator at regular intervals so that any abnormal conditions can be discovered and corrected.

e. Stop the generator in accordance with the instructions supplied by the manufacturer of the prime mover.

f. When the generator set is operated as a standby unit open the Output Circuit Breaker following shutdown of the generator set.

3.4 OPERATING INSTRUCTIONS FOR PARALLEL OPERATION OF GENERATORS

3.4.1 The KAMAG 14 voltage regulator can be equipped for parallel operation as an option in the factory or by a qualified field representative. With the paralleling option, two or more generators may be paralleled successfully regardless of rating as long as each supplies no more than its full KW load rating. Do not attempt to operate in parallel any KAMAG generators that do not include the paralleling option. Also do not attempt to parallel a KAMAG generator with the commercial power lines.

CAUTION

DO NOT CLOSE THE LOAD CIRCUIT BREAKER OF THE GENERATOR TO BE PARALLELED WITH ONE THAT IS ON THE LINE, UNTIL THE GENERATORS HAVE BEEN CHECKED FOR PROPER PHASE ROTATION AND ADJUSTED FOR SYNCHRONIZATION AS DETAILED IN THE FOLLOWING PARAGRAPHS.

3.5 PHASE ROTATION

3.5.1 Before placing two or more three-phase generators in parallel, make certain the generators have the same phase rotation. This can be accomplished by connecting a three phase induction motor to each of the generators and checking the rotation of the motor. Care must be taken to make certain motor terminals are connected to the corresponding generator or bus terminals for each test. Phase rotation will be the same if the motor rotates in the same direction when connected to either generator.

3.5.2 If the motor rotates in the wrong direction when connected to one of the generators, reverse any two of the three generator leads (except neutral lines). Recheck motor rotation and continue checks until the induction motor rotates in the correct direction.

3.6 SYNCHRONIZING PARALLELED GENERATORS

3.6.1 Do not attempt to parallel generators until each machine has been checked for proper phase rotation and that each generator is adjusted for the required system voltage with the line switch open.

3.6.2 If a synchroscope is not available, generators can be synchronized by using incandescent lamps connected in the load circuit as shown in figure 3-1. Make certain that the total voltage rating of the series lamps equals the voltage rating of the generator.

3.6.3 Synchronize the generators by varying the speed of the incoming generator until fluctuation of the lamps is very slow. When the lamps are dark close the line switch. Care must be taken to close the line switch at the instant the lamps are dark.

WARNING

EXERCISE EXTREME CAUTION WHEN USING THIS METHOD OF SYNCHRONIZING GENERATORS TO AVOID EXPOSURE TO DANGEROUS VOLTAGES.

3.7 DIVISION OF POWER LOAD AMONG PARALLELED GENERATORS

3.7.1 Adjust the engine governors in accordance with the engine manufacturer's instructions. Division of kilowatt or actual power load among generators operating in parallel is practically independent of generator excitation. Do not attempt to vary the amount of kilowatt load among paralleled generators by making adjustments to the voltage regulator.

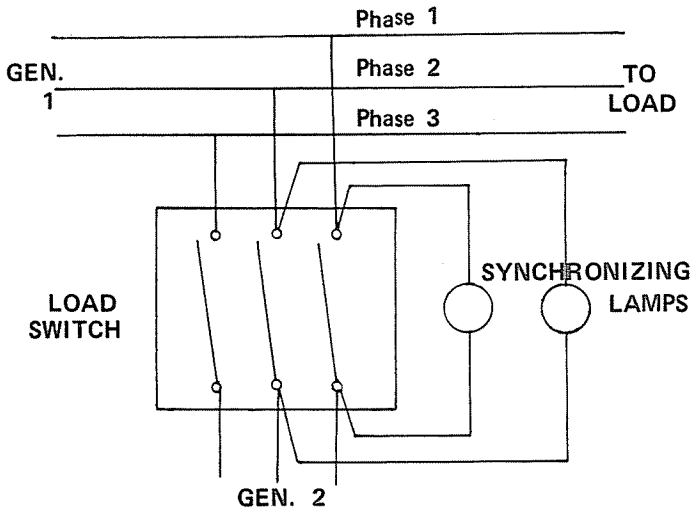

FIGURE 3-1 SYNCHRONIZING PARALLELED GENERATOR USING SYNCHRONIZING LIGHT

3.8 DIVISION OF REACTIVE KVA AMONG PARALLELED GENERATORS

3.8.1 Division of reactive KVA among paralleled generators depends upon generator excitation. Methods of correcting the excitation of individual generators should they take more or less than their share of the reactive KVA are the addition of cross-current compensation or voltage-droop controls to the voltage regulator circuit.

3.8.2 Adjustment of the cross current or voltage droop rheostat would usually be set so that there is just enough resistance in the circuit to give stable operation of the generators under reactive KVA load conditions.

3.8.3 Place generator in operation apply lagging power factor load and check voltage droop. Maximum voltage droop from no load to full load is obtained with full voltage-droop resistance. A droop of 4 to 6% is frequently employed. Adjust each generator to be paralleled for identical droop.

3.8.4 Bring all generators up to correct speed and adjust all output voltage to identical values. Synchronize and parallel generators. Load the paralleled generators and check for satisfactory division of load currents. Correct by adjusting voltage-adjust rheostats and the droop-control resistors.

3.9 STABILITY ADJUST R8

3.9.1 Stability Adjust Resistor R8 is located on the printed circuit board. Only adjust Stability Adjust R8 if during operation instability or slow reponse occurs. Turning Stability Adjust clockwise increases negative feedback, therefore increasing stability. Maximum clockwise setting will, however, result in slower response. Stability Adjust should be set so that the output voltage of the generator is stable at both no-load and full-load and response is satisfactory.

NOTE

Make certain unit is at rated speed when making voltage and stability adjustments (50 or 60 HZ., whichever is being used.

3.10 ENGINE IDLE SWITCH

3.10.1 In applications where generator set is equipped with an engine idle switch for underfrequency protection of the generator, operate switch as follows:

a. Close switch (set to idle position) when generator is operating underspeed, such as engine warm-up at idle speed.

b. Open switch (set to run position) when generator set is brought up to rated speed.

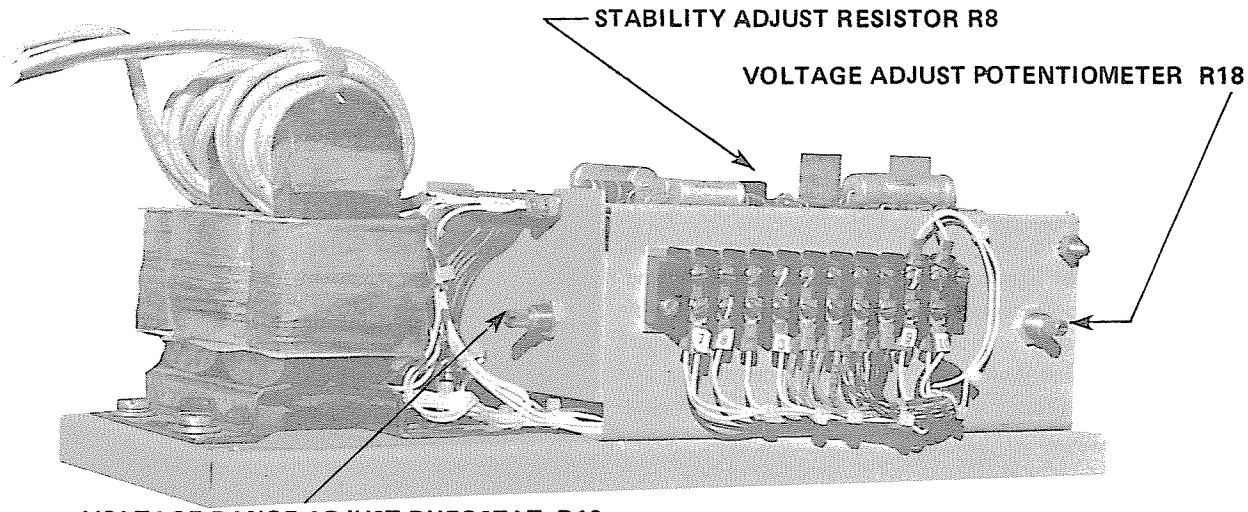

FIGURE 3-2 SIDE VIEW' VOLTAGE REGULATOR

NOTE: When requested, R18 may be remote mounted at location other than regulator chassis.

SECTION 4 MAINTENANCE

4.1 PREVENTIVE MAINTENANCE

4.1.1 Preventive maintenance is the practice of inspecting and cleaning the generator set and eliminating minor disorders before they become serious. A routine regular preventive maintenance program practiced conscientiously will ensure peak performance, lengthen the life of the generator, and eliminate or at least greatly reduce breakdown time.

4.1.2 The preventive maintenance schedule described in Table E enclosed as a guide for establishing a preventive maintenance program for generators operating under standard conditions. The specific operating conditions should be analyzed by the user of the equipment and preventive maintenance program established accordingly. When preventive maintenance inspection determines cleaning is necessary, clean the generator and controls as described in para 4.3.1.

TABLE E

PREVENTIVE MAINTENANCE SCHEDULE
1. Inspect lead wires and control devices wiring for cracked insulation and loose terminals.
2. Inspect control equipment for loose mounting hardware.
3. Inspect control devices for accumulation of dust, moisture and other foreign matter.
4. Clean the outside of the generator assembly and ventilating screens.
5. When dust or moisture is excessive, clean and/or dry the inside of generator assembly.
6. With unit running check control devices and meters for correct adjustment and operation.
7. With unit running observe any unusual noise or vibration. Refer to troubleshooting chart for possible causes of noise and vibration.

4.2 BEARING LUBRICATION INFORMATION

4.2.1 KAMAG 14 generators are equipped with shielded ball bearings. Periodic replenishment of grease is normally not required. Occasional repacking of bearings may be a worthwhile procedure, depending upon generator application. Several years of operation can normally be expected before replacement or repacking bearings becomes necessary. Major overhaul of the generator or prime mover is a good time to inspect bearings and then either replace or repack them depending on their condition.

4.2.2 If bearings are to be repacked, fill approximately ½ full; using a good grade of ball bearing grease which is recommended for electrical motor service. The grease should be capable of retaining satisfactory lubricating qualities to a temperature of +240 degrees fahrenheit or 115.5 degrees centigrade and will also lubricate satisfactorily at the lowest ambient temperature surrounding the generator.

4.3 CLEANING

4.3.1 When inspection determines cleaning is necessary clean the generator and controls as follows:

a. Wipe loose dirt from exterior painted surfaces of generator and the generator controls panel assembly (controller) with a clean cloth. Remove stubborn accumulations of dirt with a detergent or solvent. Clean all ventilating ports with a vacuum cleaner or use filtered compressed air at a pressure of from 25 to 40 psi. or 1.75 to 2.81 KG/CM^2.

b. Clean inside of generator with a vacuum cleaner or use dry filtered compressed air at a pressure of from 25 to 40 psi or 1.75 to 2.81 KG/cm^2. Remove accumulations of grease and dirt from windings with naptha.

WARNING

EXERCISE EXTREME CARE WHEN USING NAPTHA. USE ONLY IN WELL VENTILATED FLAME AND SPARK FREE AREA.

c. Clean electrical contacts such as relay contacts, switch contacts and terminals with an approved contact cleaner. Do not file contacts.

4.4 WINDINGS - PROTECTION

4.4.1 Generators operating intermittently in very damp locations should be protected with space heaters. Generators placed in operation after being subjected to very low temperatures should be slowly warmed to prevent excessive condensation. Winding resistance should be checked before placing the generator in operation if the windings are wet.

4.5 INSULATION RESISTANCE TEST

4.5.1 Winding insulation resistance can be conveniently and safely tested with a hand cranked megger of not over 500 volts. The following formula is an accepted standard for measuring insulation resistance of stator windings. Winding insulation resistance measured at 500 volts DC after one minute should not be less than:

$$\text{Resistance in megohms} = \frac{\text{Rated Voltage of Machine} + 1000}{1000}$$

The above formula is satisfactory for most checks. For more information see "Recommended Practice for Insulation Resistance Testing AC Rotating Machinery". AIEE Standard No. 43.

When megging any generator winding remove all connections to associated components such as the voltage regulator, rectifier bridge, or load.

4.6 DRYING WINDINGS

4.6.1 If the insulation fails to meet the test standards the generator may be dried out by heat from a warm air oven, heat lamps or strip heaters. The temperature should not exceed 150° F or 65.5° C. The generator windings may also be dried by application of internal heat as described in paragraph 4.6.2.

WARNING

WHEN OVEN DRYING, USE A FORCED AIR CIRCULATION OVEN, NOT A RADIANT TYPE. RADIANT OVENS WILL OVERHEAT SOME GENERATOR COMPONENTS BEFORE COMPONENTS FARTHER FROM THE HEAT REACH A SATISFACTORY TEMPERATURE.

4.6.2 Drying the generator winding insulation by the application of internal heat consists of operating the generator as described in the following procedure.

a. Check for excessive accumulation (pockets) of water on generator windings. Dry as much as possible with compressed air before applying internal heat.

b. Remove generator terminal box cover. Disconnect all generator stator leads (1 through 12) from voltage regulator leads and load lines.

c. Connect generator stator leads together, to short circuit the stator windings.

d. In one of the generator leads, insert an ammeter of sufficient size to read full-load generator current.

e. Disconnect exciter field leads from F+ and F− terminals on the voltage regulator and connect a variable source of direct current to the exciter field leads.

f. Operate the generator at normal speed. Supply just enough excitation to cause rated current to flow in the generator stator windings.

g. Operate for sufficient time to ensure thorough drying of the windings. This can be determined by stopping the generator periodically and checking the insulation resistance of the windings. Insulation resistance checks at one-hour intervals are suggested. Terminate the drying-out process when measured resistance is within test standards (paragraph 4.5) and shows little change over a two to four hour period of operation.

4.7 TESTING BRUSHLESS EXCITER ROTATING RECTIFIERS WITH AN OHMMETER.

4.7.1 If a failure of the rectifier is suspected remove the generator cover and test rectifier with an ohmmeter as follows:

a. Unsolder lead from rectifier. Remove rectifier.

b. Refer to figures 4-1 and 4-3, then connect ohmmeter leads across rectifier in one direction and then the other direction. Note meter readings. The meter should indicate a low resistance in one direction and a high resistance in the other direction.

c. If the meter indicates a low resistance in both directions the rectifier is shorted. A high resistance in both directions indicates an open rectifier.

d. Replace defective rectifiers with rectifiers of the same operating characteristics as the original parts. Order by part number and include the model and type of the exciter as well as the generator serial number.

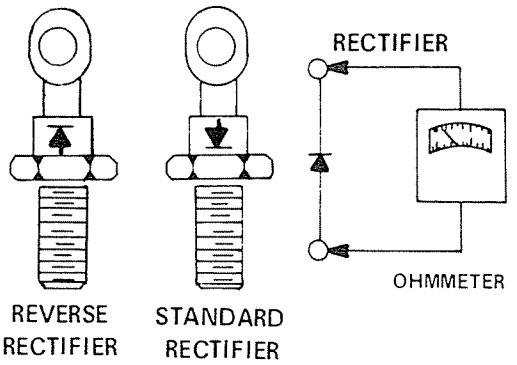

FIGURE 4-1 TESTING ROTATING RECTIFIERS WITH AN OHMMETER

4.8 TESTING BRUSHLESS EXCITER ROTATING RECTIFIRES WITH A TEST LAMP

4.8.1 If an ohmmeter is not available, field rectifiers may be tested with a test lamp consisting of standard flashlight batteries and a flashlight bulb as shown in figure 4-3. Refer to figures 4-2 and 4-4 for identification and then test as follows:

a. Unsolder lead from rectifier. Remove rectifier.

b. Connect leads of tester across rectifier in one dirction then reverse leads. The light should light when the leads are across the rectifiers in one direction and should not light when placed across the rectifier in the other direction.

c. If the light lights in both directions the rectifier is shorted. If the light does not light in either direction the rectifier is open.

4.9 TESTING SURGE PROTECTOR WITH TEST LAMP

4.9.1 Disconnect one lead and check with lamp tester. The lamp should not light when the test leads are placed across the surge protector in either direction. If the lamp lights it indicates a shorted surge protector. Replace defective surge protector with one of the same operating characteristics as the original part. Order by part number and include the serial number of the generator.

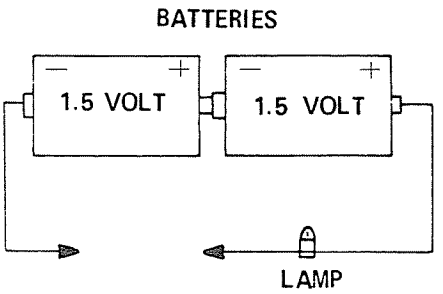

FIGURE 4-2 TEST LAMP

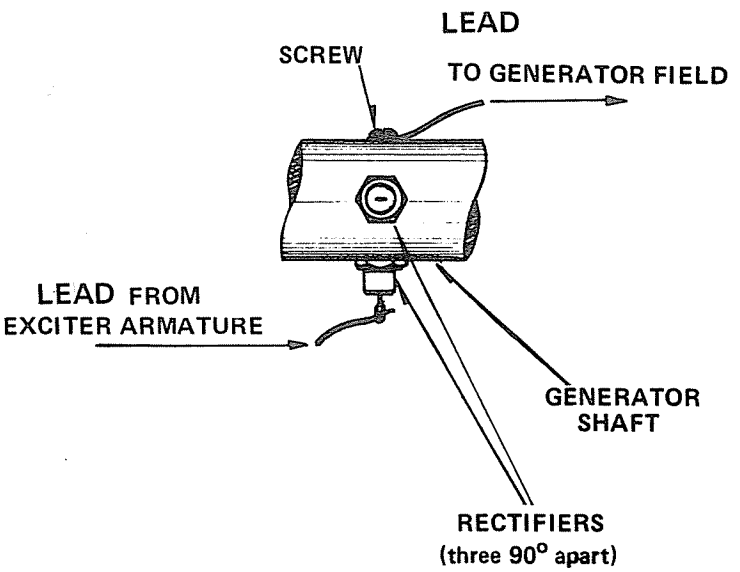

FIGURE 4-3 ROTATING RECTIFIERS

4.10 RESTORING RESIDUAL MAGNETISM

4.10.1 The direct current necessary to magnetize the alternator field is obtained from the exciter. Initially, upon starting the generator, current flow and voltage is induced into the exciter armature by the magnetic lines of force set up by the residual magnetism of the exciter field poles. Residual magnetism of the exciter field poles may be lost or weakened by a momentary reversal of the field connection, a strong neutralizing magnetic field from any source, or if the generator is not operated for a long period of time. To restore the small amount of residual magnetism necessary to begin the voltage buildup, connect a battery of from 6 to 32 volts to the exciter field coil circuit. Normally a battery of 6 to 12 volts is large enough. When the field windings have a high resistance (75-100 ohms) a larger battery voltage may be required. Connect the battery and flash field as follows:

a. Disconnect exciter field coil lead F2 (F+) at terminal F+ on the voltage regulator. Disconnect lead F1 (F-) at terminal F- on the voltage regulator.

b. Connect battery positive lead to field coil lead F2 (F+).

c. Start unit and bring up to rated speed.

d. Flash field by touching battery negative lead to field coil lead F1 (F-). Observe generator voltage buildup.

NOTE: Disconnect battery leads after approximately 3 to 5 seconds. If battery is connected for too long, overheating and subsequent damage to the exciter could occur.

e. Reflash field (steps (a) through (d) if generator output voltage does not buildup.

f. Stop unit and reconnect field coil lead F2 (F+) to terminal F+ on the voltage regulator. Reconnect lead F1 (F-) to terminal F- on the voltage regulator.

NOTE: If the polarity of the exciter is reversed by flashing the field, it may be corrected by interchanging the battery leads.

4.11 TESTING VOLTAGE REGULATOR COMPONENTS

4.11.1 Rectifiers may be tested as described in paragraphs 4.7 or 4.8.

4.11.2 Capacitors may be checked on a capacitor bridge to measure capacitance or leakage. Capacitance should not vary more than 10% of their rated value. An approximate check may be made with an ohmmeter set to a high resistance scale. The meter should initially indicate low resistance and then gradually increase until capacitor is fully charged.

4.11.3 Power Transformer Test - With rated voltage on primary windings, check the secondary voltages. Voltages measured when transformer is unloaded run up to about 10 percent higher than those taken when the transformer is wired into the circuit.

Typical transformer defects are shorts between windings, and shorted turns. These usually may be detected by checking the resistances and voltages. When the transformer overheats, and the existence of shorted turns cannot be proved by resistance measurement, check the no-load alternating current in the primary winding. This excitation current will be excessive if there are shorted turns.

4.11.4 Potentiometers and resistors may be tested with an ohmmeter. Potentiometers and adjustable resistors should be checked over their full range. Care should be taken to avoid damage when setting adjustment bands on adjustable resistors The adjustment band should be loosened until it slides freely on the resistor tube. Typical defects are open or short circuited resistors.

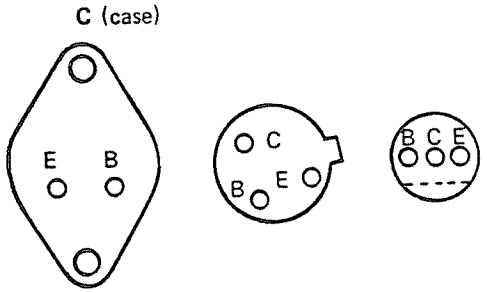

FIGURE 4-4 TRANSISTORS, PHYSICAL ILLUSTRATION BOTTOM VIEW

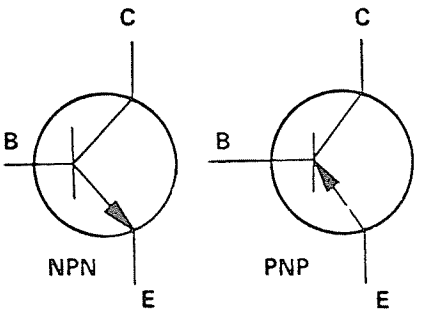

FIGURE 4-5 TRANSISTORS, SCHEMATIC

NOTE: Readings taken with resistors connected in circuit may reflect resistance of circuit rather than just the resistor.

4.11.5 Silicon Transistor Test – The following chart shows the method of testing transistors with a three-volt test lamp. Figures 4-4 and 4-5 are drawings of transistors. The light indications listed on the chart are those which will normally occur when transistor is in good condition - - not open or short circuited.

TABLE F TRANSISTOR TEST CHART

Type Transistor	Tester Positive Lead Connected To	Tester Negative Lead Connected To	Normal Light Indication
NPN	BASE	COLLECTOR	LIGHT
	BASE	EMITTER	LIGHT
	COLLECTOR	BASE	NO LIGHT
	EMITTER	BASE	NO LIGHT
PNP	BASE	COLLECTOR	NO LIGHT
	BASE	EMITTER	NO LIGHT
	COLLECTOR	BASE	LIGHT
	EMITTER	BASE	LIGHT

4.12 REMOVING BEARINGS

4.12.1 Remove the endbell to expose bearing. See "Disassembling Generator". Use a puller to remove the bearing from the shaft. Protect the shaft end with a cap. If bearing is to be used again, make certain puller applies pressure only against the bearing inner race. See figure 4.6.

4.13 INSTALLING BEARINGS

4.13.1 Heat the bearing to 250° F. or 121° C. in a clean temperature controlled circulating air oven. Start the heated bearing onto the shaft. Then use a fiber or soft metal sleeve to tap bearing into place. See figure 4-7. Make certain that pressure is applied only to the bearing inner race. Install bearing to point where inner race is against shoulder on shaft.

4.14 TROUBLESHOOTING

4.14.1 Troubleshooting is the process or recognizing malfunctions of the system, intelligently analyzing the malfunction, and making the necessary corrections to place the unit back into proper operation.

4.14.2 Between all regular preventive maintenance inspection be alert for any signs of generator set trouble. Common symptoms are listed in Table G. Correct any minor trouble immediately. Minor defects left uncorrected can cause serious damage which can result in costly repairs and down time.

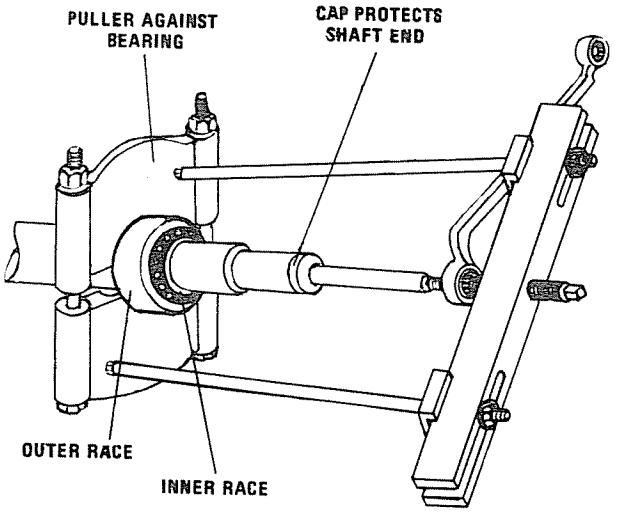

FIGURE 4-6 REMOVING BEARING

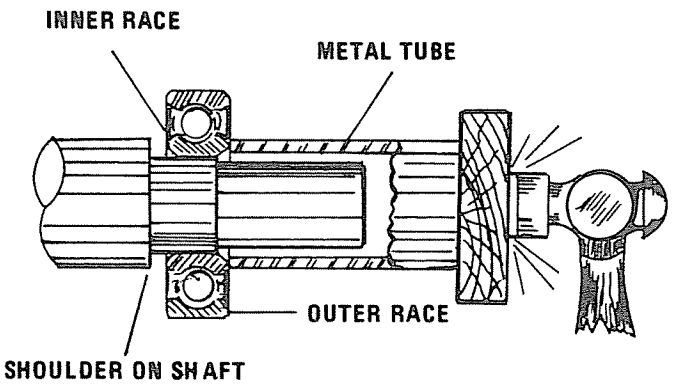

FIGURE 4-7 INSTALLING BEARING

TABLE G
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSES	REMEDY
No Voltage	Open circuit breaker of fuses (if voltage is sampled on load side of fuses or circuit breaker). Idle Switch closed.	Check. Reset circuit breaker or replace fuses if open. Open Idle Switch. (See note.)
	Open circuit in exciter field.	Check out continuity of shunt field and leads to voltage control. (Use ohmmeter or wheatstone bridge.) If open in field coils, remove exciter field assembly and return assembly to factory for repair.
	Loss of residual magnetism in the exciter field poles.	Adjust manual adjust potentiometer to full resistance. Flash field by making a flash connection of D.C. across terminals F1 to F2. See "Restoring Residual Magnetism".
	Open Circuit in stator winding	Check for continuity in windings. Return to factory for repair if open.
	Malfunction of automatic voltage regulator.	See trouble shooting of voltage regulator.
	Short Circuited generator output leads.	Clear lead to restore voltage build up.
	Open in rotating rectifiers.	Check rotating rectifiers and replace if open.
	Open in alternator field.	Check for continuity and return rotor to factory for repair if field coils are open.
	Shorted rotating rectifiers.	Check shorts and replace if faulty.
	Shorted exciter armature.	Check for short, if faulty replace.
	Shorted leads between exciter armature and generator field.	Test and repair
Low Voltage	Engine Idle Switch Closed	Open switch. (See note.)
	Improper adjustment of voltage adjust rheostat or range adjust rheostat	Adjust Rheostats. Refer to Section 3 "Operating Procedures."
	Excessive Load	Reduce load. With 3 wire, single phase and 4 wire, three phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Line loss.	Increase size of line wire.
	High resistance connection. Connections will be warm.	Make better connections.
	Shorted field.	Test field coils for possible short by checking resistance with an ohmmeter or resistance bridge. Return rotor assembly to factory for repair if alternator field coils are shorted.

NOTE: If idle switch is left closed, output voltage may be low or no output depending on amount of exciter field residual magnetism.

TABLE G cont.

SYMPTOM	POSSIBLE CAUSES	REMEDY
Low Voltage (Cont.)	Low Power factor.	Reduce inductive (motor) load. Some AC motors draw approximately the same current regardless of load. Do not use motors of larger horsepower rating than is necessary to carry the mechanical load.
	Weak field due to operating in warm temperature.	Improve the ventilation of generator. Field .current can be increased providing the generator temperature rating stamped on the nameplate is not exceeded.
	Improper voltage and/or frequency to drive motor causing low speed.	Check input voltage. Correct deficiencies. Check motor data plate for nominal operating values.
	Low speed due to improper belt adjustment on belt driven motor generator sets.	Align and adjust belt. Replace if worn excessively. Check for proper sheave size.
	Improper speed of engine driven generator set due to defective governor, ignition system, or carburetor.	Check and correct deficiencies.
Fluctuating Voltage	Voltage regulator not operating properly (if used).	Check regulator. Replace if defective.
	Prime mover speed fluctuating.	Check frequency and voltage of incoming power when generator set is motor driven. Engine governor on engine driven generator sets.
	Loose terminal or load connections.	Make better connections.
	Generator overloaded.	Reduce load to rated value.
	DC excitation voltage fluctuating.	Trace DC excitation circuit. Correct any defects.
High Voltage	Overspeed.	Correct speed of prime mover.
	Improper connection of generator.	Reconnect generator. See 1.8, generator connection diagrams.
	Improper adjustment of voltage adjust rheostat or range adjust rheostat	Adjust rheostats. Refer to Section 3 Operating Procedures.
Overheating	Clogged ventilating screens and air passages.	Clean all screens and air passages.
	Dry or defective bearings.	Lubricate dry bearings. Replace defective bearings.
	Coupling misaligned or on belt driven generators, belt too tight.	Align generator set or adjust belt.
	Generator field coils shorted or grounded.	Test field coils for shorts. Replace shorted rotor or return to factory for repair.

TABLE G cont.

SYMPTOM	POSSIBLE CAUSES	REMEDY
Vibration	Defective or dry bearing	Lubricate dry bearings. Replace defective bearings.
	Misalignment of generator and prime mover.	Align generator set.
	Generator not properly mounted.	Check mounting. Correct defective mounting.
	Transfer of vibration to generator from another source.	Isolate generator set from source of vibration by installing vibration dampeners between the generator set base and foundation.

4.15 TWO BEARING KAMAG 14 GENERATOR DISASSEMBLY INSTRUCTIONS

4.15.1 Refer to figure 4-8 and Table H for illustrated parts breakdown. Remove generator to prime mover coupling and then disassemble generator as follows:

1) Remove bolts holding endbells (3) and (17) to base. Remove generator from base.

2) Remove eyebolts (14) and bolts and nuts (15) and (16). Remove wrapper cover (13) from generator.

3) Remove terminal box cover and disconnect generator output leads and also field lead F- and F+. Remove any clips securing generator field leads to the generator frame (11).

4) Remove Drive endbell bolts (18) and washers (19) from drive endbell (17). Pull endbell from generator.

5) Remove bolts (21) and washers (22) from fan (20). Remove fan. During assembly, position fan about 1/2 inch from baffle (12).

6) Remove bolts (1) and washers (2) from endbell (3). Pull endbell from generator.

7) If exciter field windings (4) require replacement, remove bolts (5) and washers (6) that secure the exciter field to endbell (3). During assembly, install exciter field assembly with leads toward endbell.

8) Remove rotor assembly (10) from frame and stator assembly (11).

9) If rectifiers (9) require replacement, unsolder lead and then remove rectifier.

10) When replacing bearings (7) or (23), refer to procedures outlined in paragraphs 4.12 and 4.13.

4.16 SINGLE BEARING KAMAG 14 GENERATOR DISASSEMBLY INSTRUCTIONS

4.16.1 Refer to figure 4-9 and Table I for illustrated parts breakdown. Remove generator from engine mounting bolts and then disassemble generator as follows:

1) Remove bolts holding endbell (3) and adapter (17) to base. Remove generator from base

2) Remove eyebolt (14) and bolts and nuts (15) and (16). Remove wrapper cover (13).

3) Remove terminal box cover and disconnect generator output leads and also field leads F- and F+. Remove any clips securing field leads to the generator frame (11).

4) Remove endbell bolts (1) and washers (2) from endbell (3). Pull endbell from generator.

5) Remove rotor assembly (10) from drive end of generator frame (11).

6) If exciter field (4) requires replacement, remove bolts (5) and washers (6) then remove field from endbell (3). During assembly install exciter field with leads toward endbell.

7) Remove fan (20) from rotor by removing fan bolts (21) and washers (22). When unit is assembled, position fan about ½ inch from baffle (12).

8) If rotating rectifiers (9) require replacement, unsolder lead wire and then remove rectifiers.

9) When replacing bearing (7), refer to the procedures outlined in paragraph 4.12 and 4.13.

KATO KAMAG 18 SERIES GENERATORS

This manual contains Installation, Operation and Maintenance instructions for KATO KAMAG 18 series brushless synchronous revolving field generators. The generators are manufactured in both a single bearing and a two bearing line. Single bearing generators are designed for direct coupling to industrial engines while two bearing generators are designed for flexible or belt coupling to electric motors and other types of prime movers. The series is available in ratings of from 60 to 150 kilowatts. The KAMAG 18 generator incorporates an integral brushless rotating exciter and saturable transformer voltage regulator which has a built-in series boost and a solid state preamplifier. The voltage regulator is mounted in the generator terminal box. An auto voltage adjust potentiometer is standard on all units allowing manual adjustment of output voltage.

The KAMAG 18 series has the over all dependability of KATO Engineering Company products. The brushless design and use of a solid state voltage regulator eliminates all movable contacts and brushes. Absence of brushes and contacts which are subject to wear ensures maximum service life with a minimum of periodic preventive maintenance. Bearings are oversize ball bearings, fully shielded; no periodic replenishment of grease is required.

In general, the KAMAG 18 generator should require little maintenance other than keeping the unit clean.

For performance and longest service life, the following procedures are especially important:

MAKE CERTAIN THE GENERATOR IS PROPERLY CONNECTED TO THE PRIME MOVER.

MAKE CERTAIN THE GENERATOR IS CORRECTLY CONNECTED FOR THE LOAD IT IS SUPPLYING.

MAKE CERTAIN THE LOAD DOES NOT EXCEED THE GENERATOR RATING.

MAKE CERTAIN SUFFICIENT COOLANT AIR IS AVAILABLE. KEEP ALL AIR PASSAGES CLEAR OF DUST AND OTHER FOREIGN MATERIAL.

MAKE CERTAIN GENERATOR SPEED IS CORRECT – FREQUENCY IS DIRECTLY PROPORTIONAL TO GENERATOR SPEED. VARIATIONS IN SPEED WILL CAUSE VARIATIONS IN OUTPUT FREQUENCY. RUN GENERATOR 1800 RPM TO PRODUCE OUTPUT FREQUENCY OF 60 HERTZ. RUN GENERATOR 1500 RPM TO PRODUCE OUTPUT FREQUENCY OF 50 HERTZ.

WARRANTY

Kato Engineering Company warrants that the apparatus manufactured by us will deliver its rated output, providing such apparatus is properly installed, properly cared for, and properly operated under normal environmental conditions.

Standard products manufactured by Kato Engineering Company are warranted to be free from defects in workmanship and material for a period of one year from the date of shipment, and any products which are defective in workmanship or material will be repaired or replaced at the option of Kato Engineering Company. Final determination as to whether a product is actually defective rests with Kato Engineering Company. The obligation of Kato Engineering Company hereunder shall be limited solely to repair and replacement at its factory, of products that fall within the foregoing limitations, and shall be conditioned upon receipt by Kato Engineering Company of written notice within the warranty period of any alleged defects or deficiency. No products shall be returned to Kato Engineering Company without its prior consent. In no case can Kato Engineering Company accept shipping charges incurred either through return of defective items to its factory or return of repaired or replacement item to the user. Kato Engineering Company cannot assume responsibility or accept invoices for unauthorized repairs to its components, even though defective. In the case of components, parts, or units purchased by Kato Engineering Company, the obligation of Kato Engineering Company shall not exceed the settlement that it is able to obtain from the supplier thereof.

The life of the products of Kato Engineering Company depends to a large extent upon type of usage thereof, and Kato Engineering Company makes no warranty as to period of service nor as to fitness of its product for specific applications by the buyer unless Kato Engineering Company specifically agrees to otherwise in writing after the proposed usage has been made known to it. In no event will Kato Engineering Company be liable for consequential or incidental damages or for any expense incurred by Buyer due to use or sale of products sold by Kato Engineering Company.

The foregoing warranty is exclusive and in lieu of all other warranties expressed or implied, including but not limited to any warranty of merchantability or of fitness for a particular purpose.

This Warranty does not apply to experimental or developmental products.

FIGURE 1-1 KAMAG 18 AC GENERATOR

SECTION 1 INTRODUCTION AND DESCRIPTION

1.1 INTRODUCTION

1.1.1 The KAMAG 18 series by Kato Engineering Co. is a complete electrical power generating system including AC generator, brushless exciter and voltage regulator designed and built to be light enough to be easily movable, rugged enough to be durable and versatile enough to be part of any fixed installation.

1.1.2 This instruction manual has been compiled to provide receiving and inspection procedures, precautions and recommendations as to assembly to prime movers and location for operation, initial start-up and operation instructions, and routine maintenance recommendations. With proper maintenance and operation, the KAMAG 18 generator will provide many years of trouble-free service.

1.2 KAMAG 18 ELECTRICAL POWER GENERATING SYSTEM

1.2.1 The KAMAG 18 electrical power generating system can be divided into three basic components; the AC generator, brushless exciter and static regulator. Each component has been designed and built to insure maximum simplicity and reliability without sacrificing quality and performance.

1.3 KAMAG GENERATOR

1.3.1 The KAMAG Generator in a word is versatility. Many different configurations can be supplied to aid in coupling to the prime mover. The two bearing arrangement can be used wherever it is impracticable to have the power output shaft of the prime mover support the drive end of the generator rotor. KAMAG 18 generators of two bearing design use an antifriction bearing on each end of the shaft to support the rotor assembly. The two bearing type generator can be driven through any non-weight bearing coupling such as "V" belts, rubber block, spring, etc.

1.3.2 The KAMAG Generator is also manufactured in a single bearing line where the power input end of the rotor is supported by the prime mover. The generator frame and rotor can be purchased to fit any standard SAE flywheel and flywheel housing in its size range. Adaption can also be made to several commonly used non-SAE drives. A weight bearing semiflexible laminated plate coupling is furnished with the single bearing units for direct coupling to the prime mover.

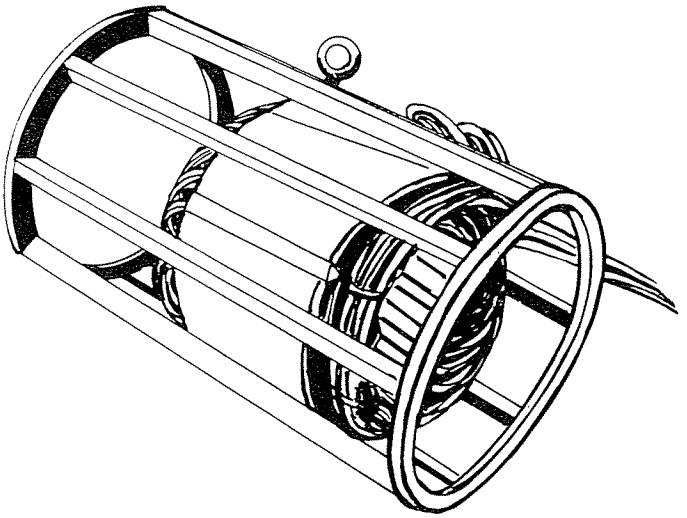

FIGURE 1-2 GENERATOR FRAME & STATOR ASSEMBLY

1.4 KAMAG BRUSHLESS EXCITER

1.4.1 The KAMAG BRUSHLESS EXCITER is a revolving armature, three phase, high frequency generator. The output is rectified by a full wave three phase rectifier bridge mounted directly on the main generator shaft. The exciter armature is pressed into position on the main generator shaft and held in place by a square key and locking nut. The exciter stator is secured to the endbell assembly. The purpose of the exciter is to provide a rotating magnetic amplifier to supply power to the main generator field.

1.4.2 By using the brushless design, components such as slip rings, commutators, brushes, or any form of sliding contacts that wear and need periodic maintenance have been eliminated. The rectifiers used in the rectifier bridge are of a type that are self protected against failure from voltage transients.

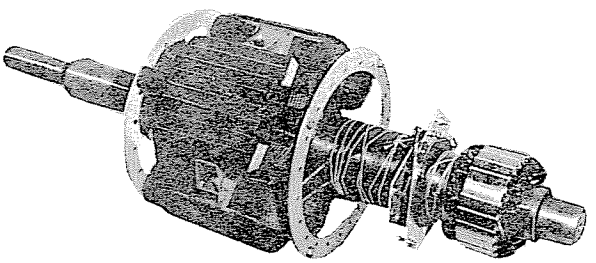

FIGURE 1-3 GENERATOR ROTOR AND EXCITER ARMATURE ASSEMBLY

1 5 KAMAG 18 POWER OUTPUT OPTIONS

1.5.1 Any KAMAG 18 generator can be operated at any of a wide range of voltages for both single and three phase, 50 or 60 Hertz. The 60 Hertz single and three phase rating of the generator can be found on the nameplate. When operating at 50 Hertz, care must be taken to reduce the load to 5/6 of the 60 Hertz rating.

For 50 Hertz operation decrease generator shaft speed to 1500 RPM and reduce load to 5/6 of 60 Hertz rating.

1.5.2 The KAMAG 18 generators are multi-voltage machines. Thus by making the proper electrical connections they can be made to produce most common single and three phase 50 and 60 Hertz voltages. The electrical connections which must be made as well as voltages available are shown on the wiring diagram provided with the generator set.

1.6 THEORY OF OPERATION

1.6.1 The generator output voltage is produced in the generator stationary armature (stator). Voltage is induced into the stator windings by a rotating magnetic field produced by the turning generator field.

1.6.2 In order for the generator field to become magnetized and produce a rotating magnetic field, a DC voltage (excitation) must be fed to the generator field coils and the generator rotor must be turning.

1.6.3 The excitation voltage is supplied by the exciter. The exciter field poles retain some permanent magnetism thus producing a magnetic field in the exciter. When the generator is started, voltage is induced in the exciter armature windings, fed to the rotating rectifiers, rectified and fed to the generator field. The generator field then becomes magnetized and produces a rotating magnetic field. Control of the degree of magnetism of the generator field and thus the voltage induced into the generator stator windings is dependent on the voltage it is supplied by the exciter. This is controlled by regulating the exciter field by controlling the field current fed to the exciter. The voltage regulator supplies and controls the field current fed to the exciter field.

SECTION 2 INSTALLATION

2.1 RECEIVING INSPECTION

2.1.1 The KAMAG 18 generator is carefully packed and crated for shipment, and can withstand most shocks incurred during transit. Before accepting shipment from the transportation company examine the crating carefully to determine if any damage has occurred during shipment. Unpack the unit as described in paragraph 2.2 and then carefully examine the sheet metal frame and exciter cover for signs of damage. Remove terminal box cover and examine the inside of the terminal box for signs of damage to wiring and components. Inspect for loosely mounted components and the presence of moisture. Inspect to make certain foreign material such as crating nails, loose bolts or packing material which may have fallen into the machine during unpacking are removed. On two-bearing machine turn the rotor by hand to make certain it rotates freely without binding. If damage is noted, determine the extent of damage and immediately notify the transportation company claims office and KATO Engineering Company. Be sure to give complete and accurate details when reporting damage.

2.1.2 If the generator is to be placed in storage repackage and crate the generator set. Recommended procedures for storage are contained in paragraph 2.2.

2.2 UNPACKING AND STORAGE

2.2.1 If the generator is received during cold weather, let the crated unit slowly warm to room temperature before removing the protective crating and packing material. This precaution will minimize the condensation of moisture on coil surfaces, eliminating the possibilities of wet windings and insulating materials which could cause early malfunctions of the generator.

2.2.2 Unpack the generator with care to avoid damage to the unit. Move the generator to the mounting location by attaching an overhead hoist to the eye-bolts installed in the generator frame. Determine that the hoist, when used, is of sufficient strength to adequately support the weight of the generator. Hoist and hoist cables should have a rating of not less than 1½ times the weight of the generator.

CAUTION

ALWAYS MAKE CERTAIN EXTREME CARE IS TAKEN WHEN MOVING THE GENERATOR TO PREVENT ITS STRIKING OTHER OBJECTS OR PERSONNEL. NEVER APPLY A LIFTING FORCE TO STRUCTURAL POINTS OTHER THAN THOSE PROVIDED FOR THAT PURPOSE.

2.2.3 If the generator is not to be installed in its operating location as soon as received, it should be stored in a clean, dry area, not subject to sudden temperature or humidity changes. If possible, storage should be in an ambient temperature of approximately normal room temperature. Units which cannot be stored in a temperature and humidty controlled area and which are to be in storage for a period of longer than six months should be prepared for storage as follows:

a. Install desiccant bags under the generator cover and inside the terminal box and vacuum seal the unit in a covering of polyethelene.

b. Adequately tag the unit to ensure that desiccant bags are removed before the generator is placed in operation.

2.3 LOCATION

2.3.1 The KAMAG 18 series generator can be installed in any well ventilated area which affords sufficient accessibility for operation and maintenance of the unit and allows a sufficient unobstructed flow of coolant air. Avoid locations which subject the generator to excessive moisture, dust, steam or the fumes from acids, alkalines or other corrosive chemicals. If such exposure cannot be avoided, establish a rigid periodic preventive maintenance schedule. The adverse effect of excessive moisture can usually be eliminated or at least greatly lessened by the use of space or strip heaters. If the generator windings have become wet, check winding insulation resistance and if low, dry windings before operating generator. Refer to paragraphs 4.4 and 4.5.

2.3.2 The foundation or supports which mount the generator and prime mover must be rigid, level and of ample size and strength to support the weight of the generator and prime mover. Although a reinforced concrete foundation usually makes the best foundation for heavy machinery, the generator and prime mover may be placed on any concrete, steel or other structural material which will adequately support the weight of the unit. Bearing loads of structural materials can be obtained by referring to engineering handbooks.

2.4 MOUNTING SINGLE BEARING GENERATORS

2.4.1 The generator can be mounted on an extension of the engine base or on a separate foundation which is properly aligned and level with the engine foundation. Install shims between the generator base and the mounting surface as necessary to level and properly align the generator with the prime mover.

2.5 COUPLING AND ALIGNMENT OF GENERATOR WITH DISK COUPLING AND ENGINE ADAPTOR

2.5.1 The disk coupling consists of several steel disks which are securely bolted to the generator rotor and to the engine flywheel. Because close tolerances are maintained in the manufacture of the engine components, generator frame and drive disks, the only alignment procedures which should normally be required are to make certain the rotor shaft and the engine flywheel are properly aligned and that the generator bearing has a nominal endclearance of: Total engine crankshaft axial movement plus 1/16 inch (1.588 millimeter). To insure proper alignment check the dimensions listed in the following steps.

NOTE: Clean accumulations of dirt or grease from mounting surfaces before checking dimensions or assembling the generator to the engine.

1. Remove generator wrapper cover and terminal box cover.

2. Check generator bearing endclearance and alignment of exciter field and exciter armature. Dimension a', of figure 2-1 should compare with dimension given in instruction INS-2-70A supplied with generator. Exciter field and exciter armature should be aligned horizontally.

3. Check the distance from the engine bell housing mounting surface and the drive disk recess (dimension C , figure 2-2) and check the distance from the generator endring mounting surface to the outside surface of the drive disks (dimension Y figure 2-2). Dimension Y should equal dimension C .

NOTE: The generator rotor shaft should be parallel with the generator frame when checking dimension Y .

If C is more than Y install additional spacers between the generator drive hub and the drive disks.

NOTE: An additional spacer is normally supplied with generator.

Katolight Service - Master Repair Manual - Page 474

If Y is more than C remove spacers from between the generator drive hub and drive disks.

4. Check the diameter of the drive disks and the flywheel drive disk recess, dimensions S and S', figure 2-2. If the drive disks are over or under size return them to the factory. Do not attempt to grind the drive disks.

5. Check to make certain drive disk and flywheel drive disk recess bolt hold centers are equal, dimensions B and B', figure 2-2. Return drive disks and give flywheel data if disks do not "match" flywheel dimensions. Never attempt to drill out drive disk holes.

6. With indicator base mounted on the flywheel and the indicator finger on the flywheel housing as shown in figure 2-4, turn the engine through one revolution. Maximum total indicator reading should not exceed .003 inch per foot diameter or approximately .025 millimeter per 100 millimeter diameter of the flywheel housing. See TABLE A. If runout exceeds limits, contact KATO Engineering Company and the engine manufacturer for recommendations. State flywheel housing size and runout recorded.

7. With indicator base mounted on the flywheel housing and the indicator finger on the drive disk recess as shown in figure 2-5, turn the engine through one revolution and check runout. Maximum total indicator reading should not exceed .003 inch per each foot diameter or approximately .025 millimeter per 100 millimeter diameter of the flywheel. Refer to TABLE A. If runout exceeds limits, contact KATO Engineering Company and the engine manufacturer for recommendations. State flywheel size and runout recorded.

2.5.2 When dimensions are satisfactory, assemble the generator to the engine as described in the following steps:

NOTE: The generator is connected to the engine by inserting bolts from the generator side and tightening them into the threaded holes in the engine flywheel and flywheel housing. Bolts must be of proper length to assure adequate threading into the holes in the engine flywheel and flywheel housing.

1. Make two pilot bolts by removing heads of bolts and starting them into the holes in the engine flywheel and flywheel housing on a line across the center of the mounting surfaces as shown in figure 2-6.

2. Install lockwashers on the generator adapter endring to bell housing bolts. Install lockwashers on the drive disk to flywheel bolts.

NOTE: If there is not sufficient clearance in flywheel to permit tightening of the bolts which secure the drive disks to the flywheel, the use of spacers as shown in figure 2-9 will usually alleviate the problem.

3. Most fans are made up of two halves. This type fan can be taken apart for more working space.

NOTE: The fan was set at the factory with clearance between the fan and baffle which would provide maximum efficiency of the fan. Before loosening and moving the fan, mark position of fan on shaft. Reinstall fan to marked position approximately ½ inch or 12.7 millimeters clearance between fan and fan baffle is normal.

4. Support the generator fan from an overhead hoist and move the generator horizontally into place. Make certain drive disks fit completely into the drive disk recess in the flywheel.

5. Install the flywheel bolts. Tighten bolts alternately and evenly. Remove the pilot bolt and install and tighten remaining bolt.

CAUTION

MAKE CERTAIN BOLTS ARE NOT OF EXCESSIVE LENGTH, SUCH THAT THEY BOTTOM OUT IN FLYWHEEL BEFORE THEY TIGHTEN AGAINST DRIVE DISKS.

6. Install and tighten alternately and evenly the flywheel housing bolts. See figure 2-7. Remove the pilot bolt and install the remaining bolt.

CAUTION

MAKE CERTAIN BOLTS DO NOT BOTTOM OUT BEFORE THEY SECURELY HOLD GENERATOR ADAPTER AGAINST THE FLYWHEEL HOUSING.

7. Retighten each bolt completely around the mounting of both the disk coupling and generator adapter.

8. Use a feeler gauge to see if there is a gap between the generator mounting feet and the generator mounting base. Add shims as necessary between the generator mounting feet and the base and then bolt the generator to the base.

9. If space permits, attach a dial indicator to the generator adapter with the dial indicator point on the generator shaft as shown in figure 2-8. Turn the engine through one revolution. Maximum total indicator reading should not exceed .005 inch or .127 millimeter.

NOTE: Fan must be moved to permit access to dial indicator.

10. When alignment checks are satisfactory, reposition and tighten fan.

NOTE: Install fan to its original position on shaft. This should have been indicated by marking the shaft before moving or removing fan. Fan should be between ¼ and ½ inch or 6.35 and 12.7 millimeter from baffle when properly positioned.

2.5.3 After coupling and alignment of the generator and engine is complete but before placing generator set in operation, check clearance between generator stationary and rotating parts, especially the exciter field and exciter armature. Replace all covers and guards before placing generator in operation.

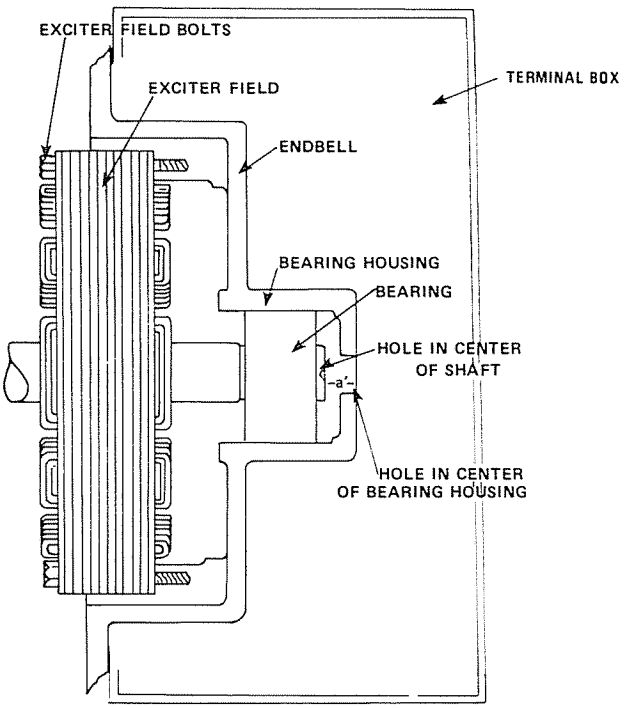

FIGURE 2-1 CHECKING BEARING END CLEARANCE Refer to Instruction INS-2-70A supplied with generator.

2.6 MOUNTING TWO BEARING GENERATORS

2.6.1 Two-bearing belt driven generators can be mounted on an extension of the prime mover base or on a separate foundation. Two-bearing generators which are connected to the prime mover by solid or flexible couplings or gear drives must be mounted on a rigid base. This base must provide mounting for both the generator and prime mover. The base must be placed on a level foundation and secured in place before the prime mover and generator are aligned. Refer to paragraphs 2.7 through 2.16.

2.7 SELECTION OF DRIVES FOR TWO BEARING GENERATORS

2.7.1 Satisfactory generator operation will depend upon careful selection of drive couplings. In general, solid couplings are not recommended except when the generator and prime mover frames are directly connected and belt drives should not be used when belt speed exceeds 5000 feet per minute or 1524 meters per minute.

2.8 BELT DRIVES - GENERAL INFORMATION

2.8.1 Proper alignment and tightness of belt drives is essential. Improper alignment and belt tightness will increase belt wear as well as increase bearing loads and vibration. Select belt drive in accordance with belt manufacturer's specifications. Make certain generator and prime mover are rigidly mounted. In general, belt drives are not recommended when belt speed exceeds 5000 feet per minute.

2.9 V - BELT

2.9.1 Use only matched belt sets and avoid minimum pitch sheaves and belts. Follow the V-belt manufacturer's specifications or NEMA limits for sheave pitch.

2.9.2 Make certain the shaft axis of the prime mover and generator are paralleled. Belts must enter and leave sheaves with no side bending. Tighten just enough to prevent slippage at full load. Never grease or use belt dressing on belts.

2.10 FLAT BELT

2.10.1 Selection of belts and pulleys of ample width will reduce amount of tension required to prevent slippage at full load. Lower belt tension reduces bearing loads and belt wear.

2.10.2 Position the pulleys so crowns are in the same plane. Make certain motors and generator shafts are paralleled. Observe belt manufacturer's or NEMA limits for pulley sizes.

2.11 GEAR BELTS (TIMING BELTS)

2.11.1 In general, installation of gear belts will be the same as for flat belts. The following precautions should be taken when installing a gearbelt drive:

a. Gearbelts should be installed with snug fit, neither too tight or too loose. High initial tension is not necessary but when torque is unusually high a loose belt may "jump grooves." If the belt jumps the grooves the tension should be increased gradually until satisfactory operation is attained.

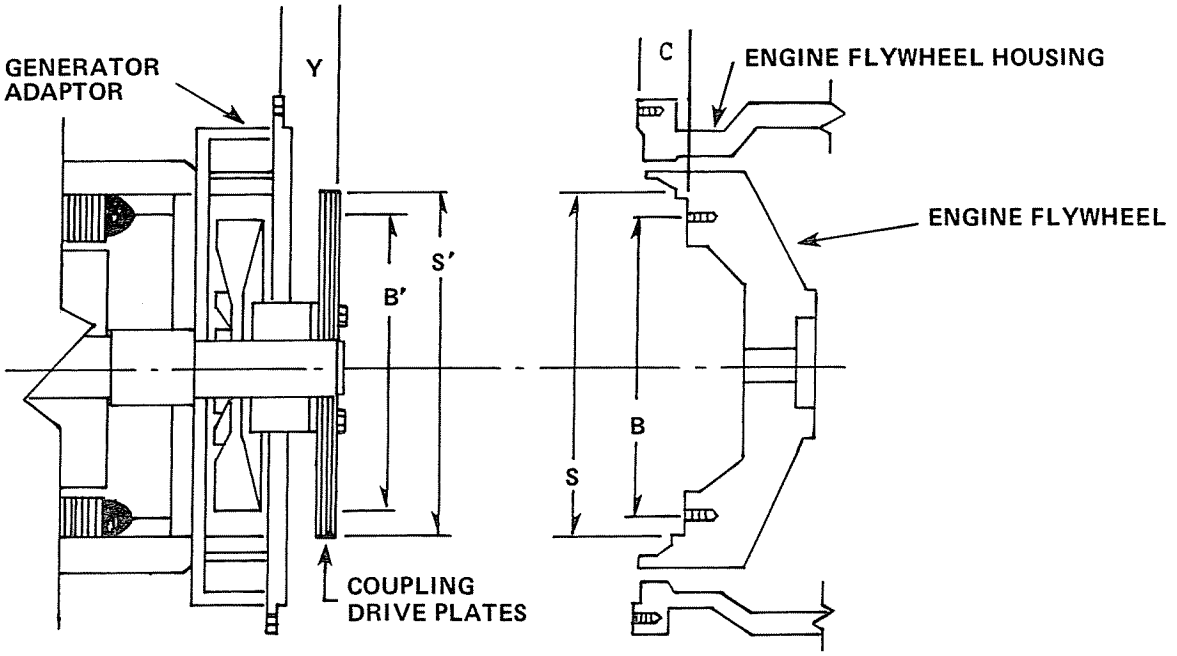

FIGURE 2-2 ENGINE AND GENERATOR COUPLING DIMENSIONS

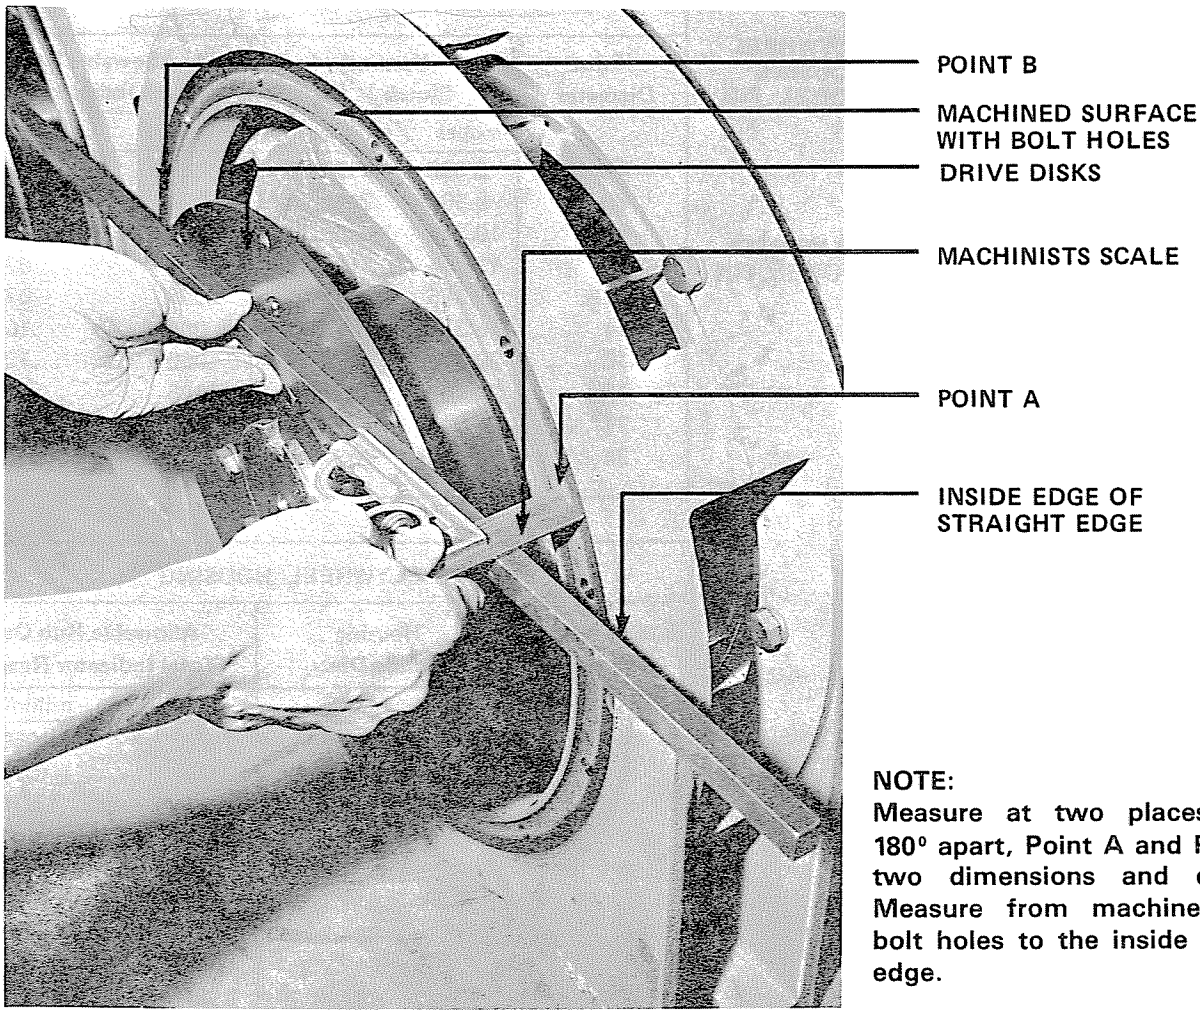

NOTE:
Measure at two places approximately 180° apart, Point A and Point B. Add the two dimensions and divide by two. Measure from machined surface with bolt holes to the inside edge of straight edge.

FIGURE 2-3 MEASURING DISTANCE FROM GENERATOR ADAPTER TO DRIVE DISKS, DIMENSION Y.

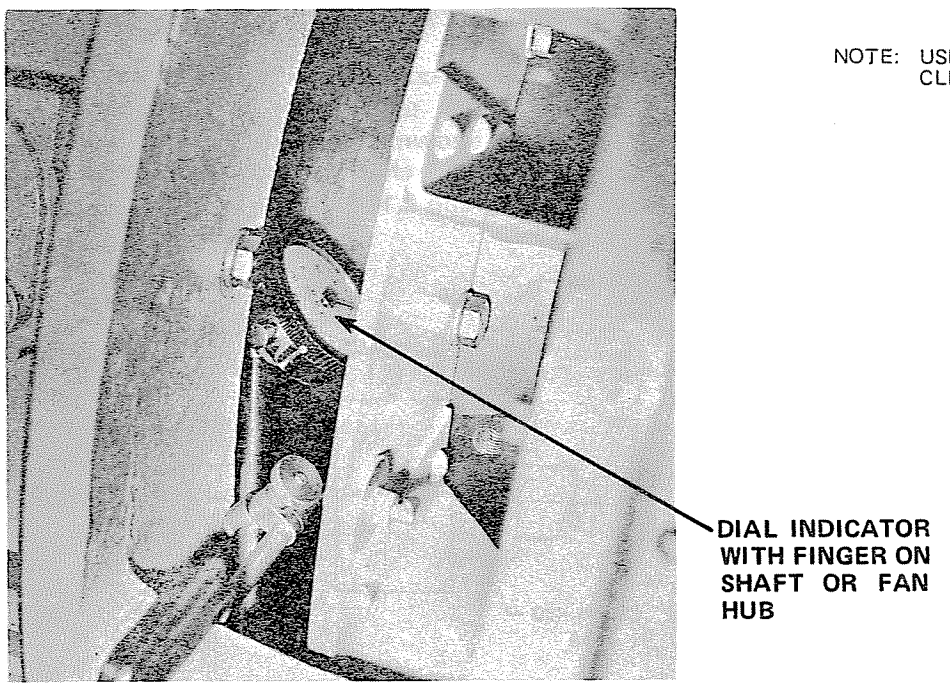
FIGURE 2-7 MOUNTING GENERATOR TO BASE



GURE 2-8 CHECKING GENERATOR SHAFT RUNOUT

NOTE: USE SPACERS ONLY SHOULD INSUFFICIENT CLEARANCE NOT PERMIT TIGHTENING BOLTS

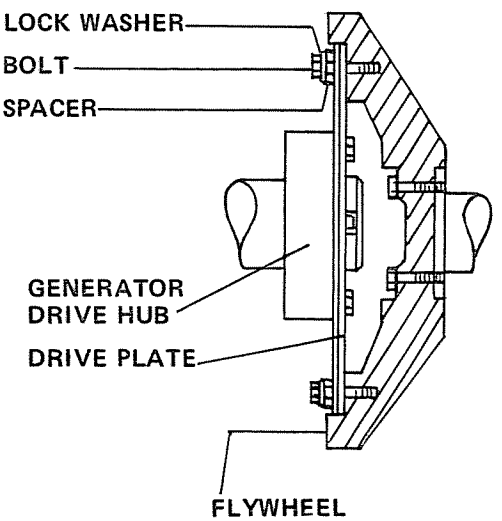


FIGURE 2-9 CROSS-SECTIONAL VIEW - DRIVE DISKS AND FLYWHEEL

b. Be sure that shafts are parallel and pulleys are in alignment. On a long center drive, because of the tendency of the belt to run against one flange, it is sometimes advisable to offset the driven pulley to compensate.

c. On a long center drive, it is imperative that belt sag is not enough to permit teeth in the slack side to engage the teeth on the tight side.

d. It is important that both prime mover and generator are mounted rigidly to prevent variation in belt tension.

e. Although belt tension requires little attention after initial installation, provision should be made for some center distance adjustment for ease in installing and removing belt. Do not force belt over flange of pulley.

2.12 GEAR AND FLEXIBLE COUPLINGS - GENERAL INFORMATION

2.12.1 When drives of these types are used instead of belt drives the prime mover and generator shafts must be carefully aligned and following alignment, the motor and generator must be firmly mounted to a rigid base to prevent misalignment of the unit shafts during operation. Excessive misalignment may be the cause of vibration, noisy operation, excessive coupling or gear wear or premature bearing failure.

2.13 GEAR DRIVE

2.13.1 Accurate alignment and rigid mounting are essential for satisfactory operation with gear drives. Pitch diameter and width should not be outside recommended NEMA limits. Avoid use of couplings which will impose excessive thrust on bearings.

2.13.2 In all cases, gear teeth must be centered with each other. Gear faces must be parallel and correct shaft center distance maintained. Avoid engagement of teeth so deep that they will bind or deflect. Refer to National Gear Manufacturers Association specifications.

2.13.3 Test for proper alignment by rotating shafts by hand. Check for backlash through at least one revolution of the shafts. Check backlash and gear face parallelism after tightening mounting bolts. Install or remove shims from under mounting feet to bring gear faces parallel.

2.14 INSTALLATION AND ALIGNMENT OF FLEXIBLE COUPLED DRIVES

2.14.1 The procedures outlined are for aligning flexible coupled drives. Follow the tolerances specified by the coupling manufacturer if they are less than described in this manual.

2.14.2 Install coupling hubs on generator and drive shafts in accordance with the installation procedures supplied by the maufacturer of the coupling. Then check for angular misalignment by scribing a reference mark on the coupling hub at the button or finger of the indicator to mark its position on the hub. Rotate both shafts simultaneously, keeping the finger or button of the indicator at the reference marks on the coupling hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to figure 2-10 for test setup.

ANGULAR MISALIGNMENT OF THE SHAFTS MUST NOT EXCEED .001 INCH FOR EACH INCH (0.01 MILLIMETER FOR EACH CENTIMETER) OF RADIUS OF THE COUPLING HUB TOTAL INDICATOR READING.

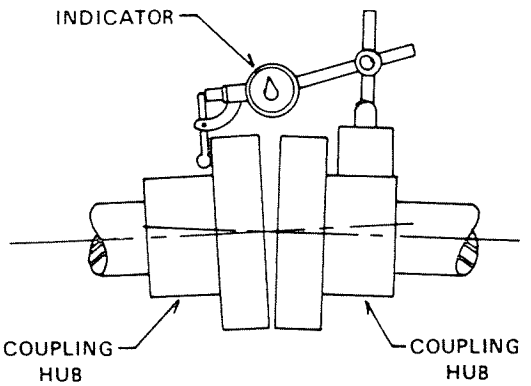

FIGURE 2-10. TESTING ANGULAR ALIGNMENT OF MOTOR AND GENERATOR SHAFTS

NOTE: If the motor generator set is moved to a new location, make test setup with coupling installed as shown in figure 2-11 and then rotate shafts and check alignment as described in paragraph 2.14.2.

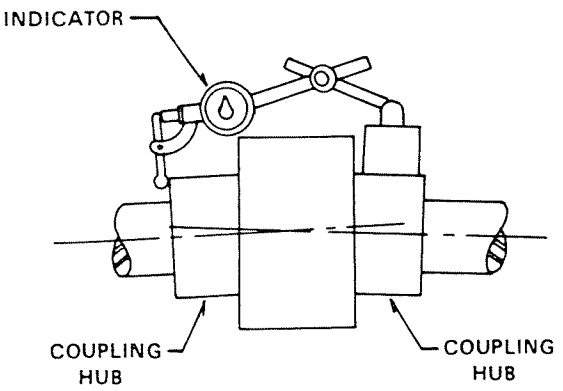

FIGURE 2-11 TESTING ANGULAR ALIGNMENT OF MOTOR & GENERATOR SHAFTS FOLLOWING COUPLING INSTALLATION

2.14.3 If angular misalignment is excessive, loosen motor and generator mounting bolts and place slotted shims under motor and generator mounting pads, as necessary, to correct alignment. Re-check alignment. Install or remove shims from under the mounting pads until aligned.

2.14.4 Check for parallel shaft (run-out) alignment by scribing a reference mark on the ground or machine diameter of the coupling hub at the finger or button of the indicator. Rotate both shafts simultaneously, keeping the button or finger of the indicator at the reference mark on the hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to figure 2-12 for test set-up.

TOTAL RUN-OUT BETWEEN HUBS SHOULD NOT EXCEED .002 OF AN INCH OR .0508 MILLIMETER.

2.14.5 When run-out between hubs is excessive, install or remove shims from under each of the motor or generator mounting pads; then recheck alignment. Add or remove shims until shafts are parallel. Tighten motor and generator mounting bolts following angular and run-out alignment. Check base mounting bolts for tightness. Re-check alignment before operating unit.

NOTE: If the motor generator set is moved to a new location check for parallel alignment by making test setup as shown in figure 2-13 and then rotate shafts and check alignment as described in paragraph 2.14.4.

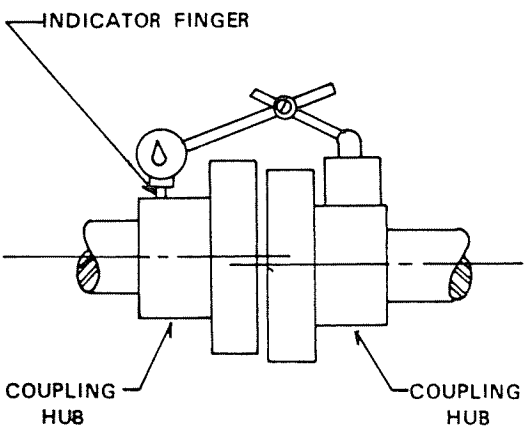

FIGURE 2-12. TESTING PARALLEL ALIGNMENT OF MOTOR AND GENERATOR SHAFTS

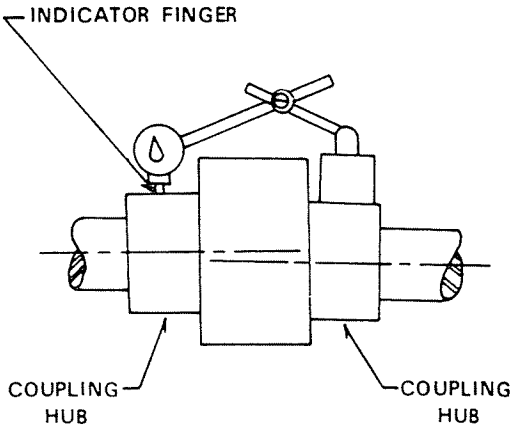

FIGURE 2-13. TESTING PARALLEL ALIGNMENT OF MOTOR AND GENERATOR SHAFTS FOLLOWING COUPLING INSTALLATION

2.15 VIBRATION

2.15.1 After alignment of motor generator set has been completed, run unit at no load and check for excessive vibration (See Operation Instructions, Section 3). If vibration is excessive loosen one motor mounting bolt slightly and if vibration decreases, add shims until retightening of bolt reduces or eliminates vibration. Repeat in turn for all motor mounting bolts.

2.15.2 When vibration and alignment of motor are within limits, run motor generator set at low load and check again for vibration. If excessive, add shims under generator mounting pads in same manner as for the motor. Re-check alignment after any change in shims to control vibration.

2.16 DOWELING

2.16.1 Doweling generator sets will prevent movement of the units during operation should the mounting bolts loosen slightly. Install dowels as follows:

a. Check the alignment after the generator set has been in operation about 40 hours. Correct alignment if not satisfactory (refer to preceding paragraphs).

b. Through opposite generator pads drill holes through and into the base. Holes should have a diameter slightly smaller than the dowel pin.

c. Ream the holes to the proper diameter for the pins, clean out chips and then install pins.

d. Repeat procedure for doweling of motor.

NOTE: Dowel prime movers (engine or motor) manufactured by others than Kato Engineering Company in accordance with the instructions supplied by the manufacturer of the prime mover.

2.17 PROTECTIVE DEVICES

2.17.1 Engine driven sets must be protected with adequate engine governors and against excessive over-speed. Refer to National Electrical Code and local electrical codes for minimum electrical requirements for the generator set. The output to the load of the KAMAG generator should always be protected with an overload protection device - circuit breaker or fuses.

2.18 ELECTRICAL CONNECTIONS

2.18.1 Before connecting the generator to the electrical power load, check nameplate for the electrical characteristics and connect the generator exactly as shown in the connection diagrams supplied with the generator set. Refer to National Electrical Code or applicable local regulations for minimum specifications for wire size, conduit and protective devices.

SECTION 3 OPERATION

3.1 PRE-OPERATION EQUIPMENT CHECK

3.1.1 After the KAMAG 18 AC generator is completely installed and wired, but before operating the unit for the first time, perform a check of the following equipment as follows:

a. If the generator has been subjected to extreme dampness during shipment or storage it may be necessary to dry out windings before placing the unit in operation. Refer to the procedures for testing winding insulation resistance and the procedures for drying windings described in Section 4 of this manual. Generators placed in operation after being subjected to very low temperatures should be slowly warmed to prevent condensation.

b. Check all interconnecting wiring against the connection diagrams supplied with the generator set. Make certain connections are insulated and taped.

c. Make certain no foreign objects are lodged in the generator. Remove all tools and shop cloths from the vicinity of the equipment.

d. Make certain all covers and guards are installed.

3.2 INITIAL START PROCEDURES FOR THE KAMAG 18 GENERATOR

3.2.1 After installation is complete and the checks listed in paragraph 3.1.1 have been completed, make an initial start and operational checkout of the equipment listed in the following general instructions:

a. Open the Output Circuit Breaker to disconnect the generator from the load.

b. Turn AUTO VOLTAGE ADJUST potentiometer to maximum resistance (full counter-clockwise).

c. Start the generator set in accordance with the prime mover manufacturer's specifications. Bring up to rated speed.

NOTE: If engine idle switch is used, set switch to run position when generator is at rated speed.

d. Stop generator set. Check rotation as unit slows to stop.

e. Again start generator set and bring up to rated speed. Monitoring output voltage with a voltmeter, turn AUTO VOLTAGE ADJUST potentiometer slowly clockwise to obtain desired voltage.

NOTE: If desired voltage cannot be obtained by turning the AUTO VOLTAGE ADJUST potentiometer it may be necessary to adjust the VOLTAGE RANGE ADJUST potentiometer. Turning potentiometers clockwise increases voltage by decreasing resistance and turning potentiometers counter-clockwise decreases voltage by increasing resistance.

f. Start and stop generator set several times; observe any unusual conditions such as excessive noise or vibration. Allow sufficient time between starts for cooling.

g. Close Output Circuit Breaker and apply a light load. Adjust AUTO VOLTAGE ADJUST potentiometer to obtain desired output voltage. Slowly increase load to generator rated power factor fully load value. Adjust AUTO VOLTAGE ADJUST potentiometer as necessary, to obtain desired output voltage.

h. Check voltage regulation. If voltage is not stable or response is slow, adjustment of the Stability Adjust resistor may be necessary. Refer to procedure given in the Voltage Regulation Instruction Manual.

i. During operation, observe the generator at regular intervals so that any abnormal conditions can be corrected before serious damage occurs.

j. With a steady rated power factor full load applied, check current on each line. Use clip-on ammeter if an ammeter is not incorporated in generator set.

k. Check line voltage. On three phase, phase 1 to 2, phase 2 to 3 and phase 1 to 3. On single phase: L1 to L2, L1 to N and L2 to N.

3.3 SINGLE GENERATOR OPERATION INSTRUCTIONS

3.3.1 If generator windings are wet, check winding insulation resistance and dry windings before operating generator. Refer to Section 4, paragraphs 4.3 and 4.4.

3.3.2 Start and operate the generator set in accordance with the following general instructions:

a. Start the generator set in accordance with the operating instructions supplied by the manufacturer of the prime mover. Operate at rated speed.

NOTE: If engine idle switch is provided, set to run position when generator is at rated speed.

b. When the AUTO VOLTAGE ADJUST potentiometer and VOLTAGE RANGE ADJUST potentiometer has been adjusted to provide the desired output voltage, no further adjustment of these devices is required prior to placing the generator set in operation. If previous voltage setting is unknown, turn the AUTO VOLTAGE ADJUST potentiometer to midpoint position before placing set in operation. During operation turn AUTO VOLTAGE ADJUST potentiometer to obtain desired output voltage.

NOTE: If desired voltage cannot be obtained, the Voltage Range Adjust potentiometer may need adjustment. Turning potentiometers clockwise increases voltage and when they are turned counter-clockwise voltage will decrease.

c. Check voltage regulation with rated power factor load applied. Refer to procedures outlined in paragraph 3.2.1, if output voltage or voltage regulation is not satisfactory.

d. During operation, observe the generator at regular intervals so that any abnormal conditions can be discovered and corrected.

e. Stop the generator in accordance with the instructions supplied by the manufacturer of the prime mover.

f. When the generator set is operated as a standby unit open the Output Circuit Breaker following shutdown of the generator set.

3.4 OPERATING INSTRUCTIONS FOR PARALLEL OPERATION OF GENERATORS

3.4.1 The voltage regulator must contain parallel operation components. Refer to the voltage regulator instruction manual. With the paralleling option, two or more generators may be paralleled successfully regardless of rating as long as each supplies no more than its full KW load rating. Do not attempt to operate in parallel any KAMAG generators that do not include the paralleling option. Also do not attempt to parallel a KAMAG generator with the commercial power lines.

CAUTION

DO NOT CLOSE THE LOAD CIRCUIT BREAKER OF THE GENERATOR TO BE PARALLELED WITH ONE THAT IS ON THE LINE, UNTIL THE GENERATORS HAVE BEEN CHECKED FOR PROPER PHASE ROTATION AND ADJUSTED FOR SYNCHRONIZATION AS DETAILED IN THE FOLLOWING PARAGRAPHS.

3.5 PHASE ROTATION

3.5.1 Before placing two or more three-phase generators in parallel, make certain the generators have the same phase rotation. This can be accomplished by connecting a three phase induction motor to each of the generators and checking the rotation of the motor. Care must be taken to make certain motor terminals are connected to the corresponding generator or bus terminals for each test. Phase rotation will be the same if the motor rotates in the same direction when connected to either generator.

3.5.2 If the motor rotates in the wrong direction when connected to one of the generators, reverse any two of the three generator leads (except the neutral lines). Recheck motor rotation and continue checks until the induction motor rotates in the correct direction.

3.6 SYNCHRONIZING PARALLELED GENERATORS

3.6.1 Do not attempt to parallel generators until each machine has been checked for proper phase rotation and that each generator is adjusted for the required system voltage with the line switch open.

3.6.2 If a synchroscope is not available, generators can be synchronized by using incandescent lamps connected in the load circuit as shown in figure 3-1. Make certain that the total voltage rating of the series lamps equals the voltage rating of the generator.

3.6.3 Sychronize the generators by varying the speed of the incoming generator until fluctuation of the lamps is very slow. When the lamps are dark close the line switch. Care must be taken to close the line switch at the instant the lamps are dark.

WARNING

EXERCISE EXTREME CAUTION WHEN USING THIS METHOD OF SYNCHRONIZING GENERATORS TO AVOID EXPOSURE TO DANGEROUS VOLTAGES.

3.7 DIVISION OF POWER LOAD AMONG PARALLELED GENERATORS

3.7.1 Adjust the engine governors in accordance with the engine manufacturer's instructions. Division of kilowatt or actual power load among generators operating in parallel is practically independent of generator excitation. Do not attempt to vary the amount of kilowatt load among paralleled generators by making adjustments to the voltage regulator.

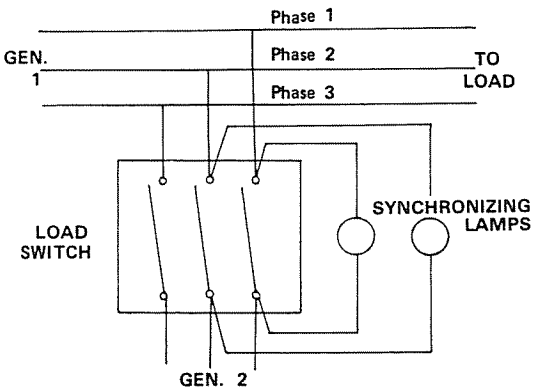

FIGURE 3-1 SYNCHRONIZING PARALLELED GENERATOR USING SYNCHRONIZING LIGHT

3.8 DIVISION OF REACTIVE KVA AMONG PARALLELED GENERATORS

3.8.1 Division of reactive KVA among paralleled generators depends upon generator excitation. Methods of correcting the excitation of individual generators should they take more or less than their share of the reactive KVA are the addition of cross-current compensation or voltage-droop controls to the voltage regulator circuit.

3.8.2 Adjustment of the cross current or voltage droop rheostat would usually be set so that there is just enough resistance in the circuit to give stable operation of the generators under reactive KVA load conditions.

3.8.3 Place generator in operation. Apply lagging power factor load and check voltage droop. Maximum voltage droop from no load to full load is obtained with full voltage-droop resistance. A droop of 4 to 6% is frequently employed. Adjust each generator to be paralleled for identical droop.

3.8.4 Bring all generators up to correct speed and adjust all output voltage to identical values. Synchronize and parallel generators. Load the paralleled generators and check for satisfactory division of load currents. Correct by adjusting voltage-adjust rheostats and the droop-control resistors.

SECTION 4 MAINTENANCE

4.1 PREVENTIVE MAINTENANCE

4.1.1 Preventive maintenance is the practice of inspecting and cleaning the generator set and eliminating minor disorders before they become serious. A routine regular preventive maintenance program practiced conscientiously will ensure peak performance, lengthen the life of the generator, and eliminate or at least greatly reduce breakdown time.

4.1.2 The preventive maintenance schedule described in Table B is enclosed as a guide for establishing a preventive maintenance program for generators operating under standard conditions. The specific operating conditions should be analyzed by the user of the equipment and a preventive maintenance program established accordingly. When preventive maintenance inspection deter-

mines cleaning is necessary, clean the generator and controls as described in paragraph 4.2.1.

TABLE B

PREVENTIVE MAINTENANCE SCHEDULE
1. Inspect lead wires and control devices wiring for cracked insulation and loose terminals.
2. Inspect control equipment for loose mounting hardware.
3. Inspect control devices for accumulation of dust, moisture and other foreign matter.
4. Clean the outside of the generator assembly and ventilating screens.
5. When dust or moisture is excessive, clean and/or dry the inside of generator assembly.
6. With unit running check control devices and meters for correct adjustment and operation.
7. With unit running observe any unusual noise or vibration. Refer to trouble shooting chart for possible causes of noise and vibration.

4.2 CLEANING

4.2.1 When inspection determines cleaning is necessary clean the generator and controls as follows:

a. Wipe loose dirt from exterior painted surfaces of generator and the generator controls panel assembly (controller) with a clean cloth. Remove stubborn accumulations of dirt with a detergent or solvent. Clean all ventilating ports with a vaccuum cleaner or use filtered compressed air at a pressure of from 25 to 40 PSI.

b. Clean inside of generator with a vacuum cleaner or use dry filtered compressed air at a pressure of from 25 to 40 PSI. Remove stubborn accumulations of dirt and grease from windings with naptha.

WARNING

EXERCISE EXTREME CARE WHEN USING NAPTHA. USE ONLY IN WELL VENTILATED, FLAME AND SPARK FREE AREA.

c. Clean electrical contacts such as relay contacts switch contacts and terminals with an approved contact cleaner. Do not file contacts.

4.3 WINDINGS - PROTECTION

4.3.1 Generators operating intermittently in very damp locations should be protected with space heaters. Generators placed in operation after being subjected to very low temperatures should be slowly warmed to prevent excessive condensation. Windings resistance should be checked before placing the generator in operation if the windings are wet.

4.4 INSULATION RESISTANCE TEST

4.4.1 Winding insulation resistance can be conveniently and safely tested with a hand cranked megger of not over 500 volts. The following formula is an accepted standard for measuring insulation resistance of stator windings. Winding insulation resistance measured at 500 volts DC after one minute should not be less than:

$$\text{Resistance in megohms} = \frac{\text{Rated Voltage of Machine} + 1000}{1000}$$

The above formula is satisfactory for most checks. For more information see "Recommended Practice for Insulation Resistance Testing AC Rotating Machinery". AIEE Standard No. 43.

When megging any generator winding remove all connections to associated components such as the voltage regulator, rectifier bridge, or load.

4.5 DRYING WINDINGS

4.5.1 If the insulation fails to meet the test standards the generator may be dried out by heat from a warm air oven, heat lamps or strip heaters. The temperature should not exceed 150°F. The generator windings may also be dried by application of internal heat as described in paragraph 4.6.2.

WARNING

WHEN OVEN DRYING, USE A FORCED AIR CIRCULATION OVEN, NOT A RADIANT TYPE. RADIANT OVENS WILL OVERHEAT SOME GENERATOR COMPONENTS BEFORE COMPONENTS FARTHER FROM THE HEAT REACH A SATISFACTORY TEMPERATURE.

4.5.2 Drying the generator winding insulation by the application of internal heat consists of operating the generator as described in the following procedure.

a. Check for excessive accumulation (pockets) of water on generator windings. Dry as much as possible with compressed air before applying internal heat.

b. Remove generator terminal box cover. Disconnect all voltage stator leads (1 through 12) from voltage regulator leads and load lines.

c. Connect generator stator leads together, to short circuit the stator windings.

d. In one of the generator leads, insert an ammeter of sufficient size to read full-load generator current.

e. Disconnect exciter field leads from F+ and F— terminals on the voltage regulator and connect a variable source of direct current to the exciter field leads.

f. Operate the generator at normal speed. Supply just enough excitation to cause rated current to flow in the generator stator windings.

g. Operate for sufficient time to ensure thorough drying of the windings. This can be determined by stopping the generator periodically and checking the insulation resistance of the windings. Insulation resistance checks at one-hour intervals are suggested. Terminate the drying-out process when measured resistance is within test standards (paragraph 4.4) and shows little change over a two to four hour period of operation.

4.6 TESTING BRUSHLESS EXCITER ROTATING RECTIFIERS WITH AN OHMMETER.

4.6.1 If a failure of the rectifier is suspected remove the generator cover and test rectifier with an ohmmeter as follows:

a. Remove nut and washer holding rectifier in heat sink and lift rectifier from heat sink. Refer to figure 4.3.

b. Refer to figures 4.1 and 4.3 then connect ohmmeter leads across rectifier in one direction and then the other direction. Note meter readings. The meter should indicate a low resistance in one direction and a high resistance in the other direction.

c. If meter indicates a low resistance in both directions the rectifier is shorted. A high resistance in both directions indicates an open rectifier.

d. Replace defective rectifiers with rectifiers of the same operating characteristics as the original parts. Order by part number and include the model and type of the exciter as well as the generator serial number.

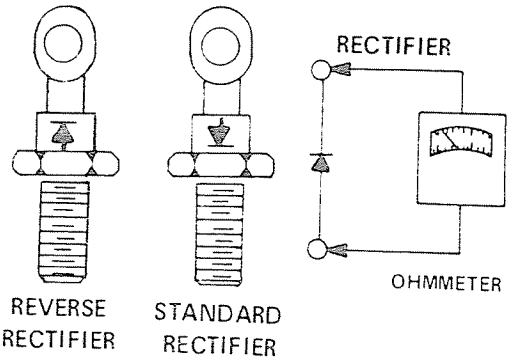

FIGURE 4-1 TESTING ROTATING RECTIFIERS WITH AN OHMMETER

4.7 TESTING BRUSHLESS EXCITER ROTATING RECTIFIERS WITH A TEST LAMP

4.7.1 If an ohmmeter is not available, field rectifiers may be tested with a test lamp consisting of standard flashlight batteries and a flashlight bulb as shown in figure 4-2. Refer to figures 4-1 and 4-3 for identification and then test as follows:

a. Remove nut and washer from rectifier and lift rectifier from heat sink.

b. Connect leads of tester across rectifier in one direction then reverse leads. The light should light when the leads are across the rectifier in one direction and should not light when placed across the rectifier in the other direction.

c. If the light lights in both directions the rectifier is shorted. If the light does not light in either direction the rectifier is open.

4.8 TESTING SURGE PROTECTOR WITH TEST LAMP

4.8.1 Disconnect one lead and check with lamp tester. The lamp should not light when the test leads are placed across the surge protector in either direction. If the lamp lights it indicates a shorted surge protector. Replace defective surge protector with one of the same operating characteristics as the original part. Order by part number and include the serial number of the generator.

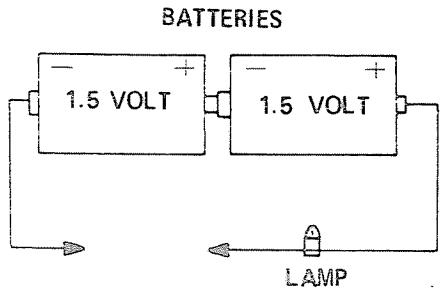

FIGURE 4-2 TEST LAMP

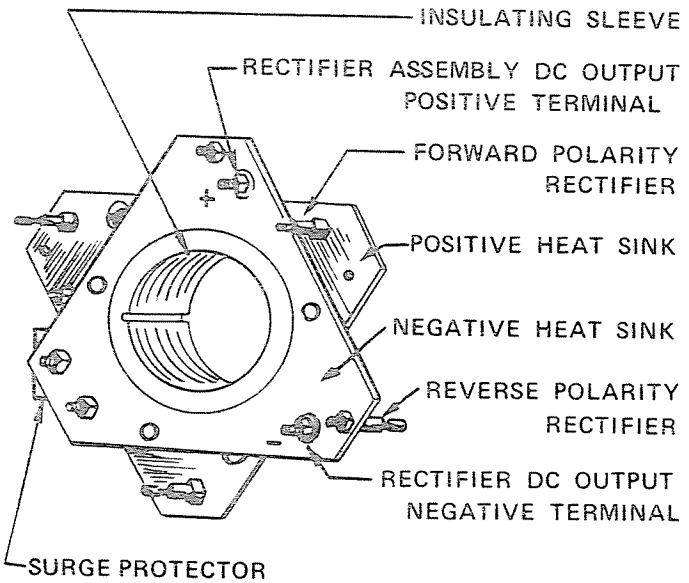

NOTE:
Three reverse polarity rectifiers located on negative heat sink.
Three forward polarity rectifiers located on positive heat sink.

FIGURE 4-3 FULL—WAVE ROTATING RECTIFIER ASSEMBLY

4.9 RESTORING RESIDUAL MAGNETISM

4.9.1 The direct current necessary to magnetize the alternator field is obtained from the exciter. Initially, upon starting the generator, current flow and voltage is induced into the exciter armature by the magnetic lines of force set up by the residual magnetism of the exciter field poles. Residual magnetism of the exciter field poles may be lost or weakened by a momentary reversal of the field connection, a strong neutralizing magnetic field from any source, or if the generator is not operated for a long period of time. To restore the small amount of residual magnetism necessary to begin the voltage buildup, connect a battery of from 6 to 32 volts to the exciter field coil circuit. Normally a battery of 6 to 12 volts is large enough. When the field windings have a high resistance (75-100 ohms) a larger battery voltage may be required. Connect the battery and flash field as follows:

a. Disconnect exciter field coil F2 (F+) at terminal F+ on the voltage regulator. Disconnect lead F1 (F—) at terminal F— on the voltage regulator.

b. Connect battery positive lead to field coil lead F2 (F+).

c. Start unit and bring up to rated speed.

d. Flash field by touching battery negative lead to field coil lead F1 (F—). Observe generator voltage buildup.

NOTE: Disconnect battery leads after approximately 3 to 5 seconds. If battery is connected for too long, overheating and subsequent damage to the exciter could occur.

e. Reflash field, steps (a) through (d), if generator output voltage does not build up.

f. Stop unit and reconnect field coil lead F2 (F+) to terminal F+on the voltage regulator. Reconnect lead F1 (F—) to terminal F— on the voltage regulator.

NOTE: If the polarity of the exciter is reversed by flashing the field, it may be corrected by interchanging the battery leads.

4.10 REMOVING BEARINGS

4.10.1 Remove the endbell to expose bearing. See "Disassembling Generator". Use a puller to remove the bearing from the shaft. Protect the shaft end with a cap. If bearing is to be used again, make certain puller applies pressure only against the bearing inner race. See figure 4-4.

4.11 INSTALLING BEARINGS

4.11.1 Heat the bearing to 250°F. in a clean temperature controlled circulating air oven. Start the heating bearing onto the shaft. Then use a fiber or soft metal sleeve to tap bearing into place. See figure 4-5. Make certain that pressure is applied only to the bearing inner race. Install bearing to point where inner race is against shoulder on shaft.

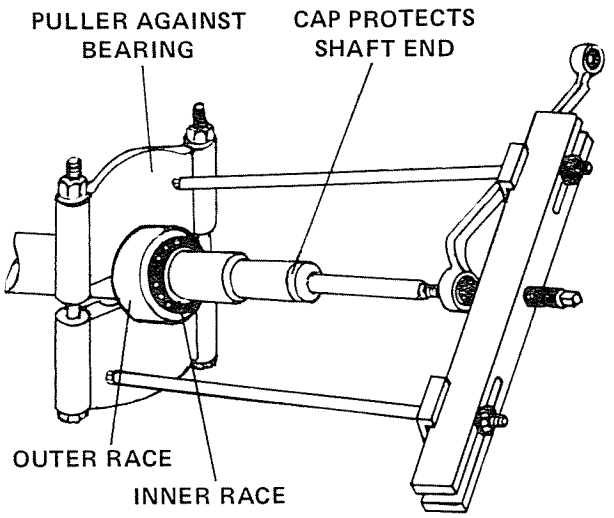

FIGURE 4-4 REMOVING BEARING

4.12 TROUBLESHOOTING

4.12.1 Troubleshooting is the process of recognizing malfunctions of the system, intelligently analyzing the malfunction, and making the necessary corrections to place the unit back into proper operation.

4.12.2 Between all regular preventive maintenance inspections be alert for any signs of generator set trouble. Common symptoms are listed in Table C. Correct any minor trouble immediately. Minor defects left uncorrected can cause serious damage which can result in costly repairs and down time.

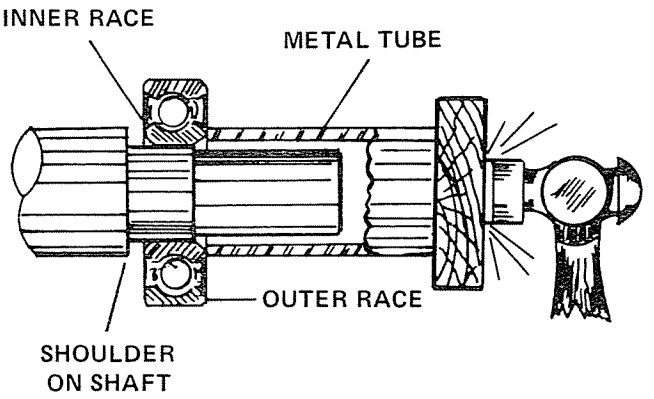

FIGURE 4-5 INSTALLING BEARING

TABLE C
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSES	REMEDY
No Voltage	Open circuit breaker of fuses (if voltage is sampled on load side of fuses or circuit breaker). Idle Switch set to idle position.	Check. Reset circuit breaker or replace fuses if open. Set Idle Switch to run position.
	Open circuit in exciter field.	Check out continuity of shunt field and leads to voltage control. (Use ohmmeter or Wheatstone bridge.) If open if field coils, remove exciter field assembly and return assembly to factory for repair.
	Loss of residual magnetism in the exciter field poles.	Adjust manual adjust potentiometer to full resistance. Flash field by making a flash connection of D.C. across terminals F1 to F2. See "Restoring Residual Magnetism"
	Open circuit in stator winding	Check for continuity in windings. Return to factory for repair if open.
	Malfunction of automatic voltage regulator.	See trouble shooting of voltage regulator.
	Short-circuited generator output leads.	Clear lead to restore voltage build up.
	Open in rotating rectifiers.	Check rotating rectifiers and replace if open.
	Open in alternator field.	Check for continuity and return rotor to factory for repair if field coils are open.
	Shorted rotating rectifiers.	Check shorts and replace if faulty.
	Shorted exciter armature.	Check for short, if faulty replace.
	Shorted leads between exciter armature and generator field.	Test and repair
Low Voltage	Engine Idle Switch set to idle position	Set switch to run position.
	Improper adjustment of voltage adjust rheostat or range adjust rheostat	Adjust rheostats. Refer to Section 3 "Operating Procedures."
	Excessive load	Reduce load. With 3 wire, single phase and 4 wire, three phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Line loss.	Increase size of line wire.
	High resistance connection. Connections will be warm.	Make better connections.
	Shorted field.	Test field coils for possible short by checking resistance with an ohmmeter or resistance bridge. Return rotor assembly to factory for repair if alternator field coils are shorted.

TABLE C - cont.

SYMPTOM	POSSIBLE CAUSES	REMEDY
Low Voltage (Cont.)	Low Power factor.	Reduce inductive (motor) load. Some AC motors draw approximately the same current regardless of load. Do not use motors of larger horsepower rating than is necessary to carry the mechanical load.
	Weak field due to operating in warm temperature.	Improve the ventilation of generator. Field current can be increased providing the generator temperature rating stamped on the nameplate is not exceeded.
	Improper voltage and/or frequency to drive motor causing low speed.	Check input voltage. Correct deficiencies. Check motor data plate for nominal operating values.
	Low speed due to improper belt adjustment on belt driven motor generator sets.	Align and adjust belt. Replace if worn excessively. Check for proper sheave size.
	Improper speed of engine driven generator set due to defective governor, ignition system, or carburetor.	Check and correct deficiencies.
Fluctuating Voltage	Voltage regulator not operating properly (if used).	Check regulator. Replace if defective.
	Prime mover speed fluctuating.	Check frequency and voltage of incoming power when generator set is motor driven. Engine governor on engine driven generator sets.
	Loose terminal or load connections.	Make better connections.
	Generator overloaded.	Reduce load to rated value.
	DC excitation voltage fluctuating.	Trace DC excitation circuit. Correct any defects.
High Voltage	Overspeed.	Correct speed of prime mover.
	Improper connection of generator.	Reconnect generator. Follow generator connection diagrams provided with the generator set.
	Improper adjustment of voltage adjust rheostat or range adjust rheostat.	Adjust rheostats. Refer to Section 3 Operating Procedures.
Overheating	Clogged ventilating screens and air passages.	Clean all screens and air passages.
	Dry or defective bearings.	Lubricate dry bearings. Replace defective bearings.
	Coupling misaligned or on belt driven generators, belt too tight.	Align generator set or adjust belt.
	Generator field coils shorted or grounded.	Test field coils for shorts. Replace shorted rotor or return to factory for repair.

TABLE C - cont.

SYMPTOM	POSSIBLE CAUSES	REMEDY
Vibration	Defective or dry bearing	Lubricate dry bearings. Replace defective bearings.
	Misalignment of generator and prime mover.	Align generator set.
	Generator not properly mounted.	Check mounting. Correct defective mounting.
	Transfer of vibration to generator from another source.	Isolate generator set from source of vibration by installing vibration dampeners between the generator set base and foundation.

4.13 TWO BEARING KAMAG 18 GENERATOR DISASSEMBLY INSTRUCTIONS

4.13.1 Refer to figure 4-6 and Table D for illustrated parts breakdown. Remove generator to prime mover coupling and then disassemble generator as follows:

1) Remove bolts holding endbells (3 and 17) to base. Remove generator from base.

2) Remove eyebolts (14) and bolts and nuts (15 and 16). Remove wrapper cover (13) from generator.

3) Remove terminal box cover and disconnect generator output leads and also field leads F— and F+. Remove any clips securing generator field leads to the generator frame (11).

4) Remove drive endbell bolts (18) and washers (19) from drive endbell (17). Pull endbell from generator.

5) Remove bolts (21) and washers (22) from fan (20). Remove fan. During assembly, position fan about ½ inch from baffle (12).

6) Remove bolts (1) and washers (2) from endbell (3). Pull endbell from generator.

7) If exciter field windings (4) require replacement, remove bolts (5) and washers (6) that secure the exciter field to endbell (3). During assembly, install exciter field assembly with leads toward endbell.

8) Remove rotor assembly (10) from frame and stator assembly (11).

9) If rectifiers (9a or 9b) require replacement, unsolder lead and then remove rectifier.

10) When replacing bearings (7 or 23), refer to procedures outlined in paragraphs 4.10 and 4.11.

4.14 SINGLE BEARING KAMAG 18 GENERATOR DISASSEMBLY INSTRUCTIONS

4.14.1 Refer to figure 4-7 and Table E for illustrated parts breakdown. Remove generator from engine mounting bolts and then dissassemble generator as follows:

1) Remove bolts holding endbell (3) and adapter (17) to base. Remove generator from base.

2) Remove eyebolt (14) and bolts and nuts (15) and (16). Remove wrapper cover (13).

3) Remove terminal box cover and disconnect generator output leads and also field leads F— and F+. Remove any clips securing field leads to the generator frame (11).

4) Remove endbell bolts (1) and washers (2) from endbell (3). Pull endbell from generator.

5) Remove rotor assembly (10) from drive end of generator frame (11).

6) If exciter field (4) requires replacement, remove bolts (5) and washers (6) then remove field from endbell (3). During assembly install exciter field with leads toward endbell.

7) Remove fan (20) from rotor by removing fan bolts (21) and washers (22). When unit is assembled, position fan about ½ inch from baffle (12).

8) If rotating rectifiers (9a or 9b) require replacement, unsolder lead wire and then remove rectifiers.

9) When replacing bearing (7), refer to the procedures outlined in paragraph 4.10 and 4.11.

REVOLVING FIELD ALTERNATING CURRENT GENERATORS WITH DIRECT CONNECTED BRUSH TYPE ROTATING DC EXCITERS

Installation -Operation and Maintenance Manual

KATO ENGINEERING
RELIANCE ELECTRIC

IDENTIFY YOUR GENERATOR BY THE FOLLOWING NUMBERS:

SERIAL NUMBER _____ **MODEL** _____ **TYPE** _____

The KATO drawings listed below are included to aid in installing, operating and maintaining your generator. Keep them with this instruction manual at all times.

Wiring Connection Drawings: _____ _____

_____ _____

Parts Drawing: _____

The purpose of this manual is to provide the user of KATO REVOLVING FIELD ALTERNATING CURRENT GENERATORS with DIRECT CONNECTED BRUSH TYPE ROTATING DC EXCITERS with the information required to install, operate, and maintain the generator

Your KATO Generator is a carefully designed, rugged machine. Only components which have proven best in reliability and performance are used. Each generator has been completely tested and inspected before shipment from the KATO factory.

Treat your generator with normal care while installing, operating and maintaining the unit and it will provide many years of very good service.

SECTION 1 INTRODUCTION & DESCRIPTION

1.1 INTRODUCTION

1.1.1 This manual contains instructions for installing, operating, and maintaining KATO Revolving Field Generators which are excited from a direct connected brush type rotating DC exciter. Also included are descriptions of the basic construction and general description of this series of generators. Instructions pertaining to installation, operation, and maintenance of the voltage regulator when used are included in the manual supplied by the manufacturer of the voltage regulator.

1.1.2 Electrical connection drawings for the specific model, type, and serial number of the generator are contained as supplementary information in a separate part of the generator manual. These drawings are the official source of information for making electrical connections or ordering replacement parts.

1.2 GENERAL DESCRIPTION

1.2.1 The alternating current generators described in this manual are of the revolving field type which have direct connected brush type rotary DC exciters. This manual describes generators of single or two bearing construction. Single bearing generators are designed for direct coupling to a stationary prime mover and two bearing generators are designed for gear, belt, or flexible coupling to a stationary prime mover. The generators are manufactured in many sizes and ratings.

1.2.2 Generator field excitation is supplied from a direct connected brush type rotary DC exciter. Regulation of the generator output voltage is accomplished by controlling the alternator field excitation current supplied by the exciter.

1.2.3 Control of the generator output is normally accomplished by using a variable resistor or rheostat in the DC exciter shunt field. The voltage adjust rheostat normally allows adjustment of generator output voltage from approximately 90 percent to 110 percent of the nominal output voltage rating. See figure 1-4, page 3.

1.2.4 When a voltage regulator is used, the output voltage of the generator is automatically controlled. The regulator senses changes in the generator output and varies the DC fed to the exciter field accordingly. An auto-voltage adjust rheostat or a variable transformer is usually incorporated in the voltage regulator circuitry to allow selection of any specific output voltage within the range of from about 90 percent to about 110 percent of the generator nominal output voltage rating. Cross current or voltage droop compensation circuitry for parallel operation of generators is available for most models of voltage regulators. See figure 1-3, page 3.

1.2.5 The generators may be supplied with various custom controls designed to provide the users power needs. Controls can be contained in separate wall mounted cubicles, in free standing control cubicles, or in a control box mounted to the generator. Mounting is dependent on the number and size of the controls or the customer's specifications.

1.2.6 All controls used on Kato Generator Sets are those which have proved, during many years of service, to be the most reliable. Should replacement of a control device be necessary, a complete line of replacement controls can be supplied by Kato Engineering Company with a minimum of "waiting" time. When generators are used as vital power units it is recommended that spare control devices such as voltage regulators be kept on hand at all times. Should a failure of these vital devices occur, install the spare and return the defective assembly to Kato Engineering Company for repair.

1.3 CONSTRUCTION

1.3.1 KATO Generators are designed by an expert power engineering staff to provide your power needs. All machines are carefully designed and constructed to ensure trouble free operation and maximum service life. The sturdy frame is fabricated of heavy steel members welded to the endbell pilot rings. A heavy steel base is welded to the frame assembly to simplify installation and alignment of the generator with the prime mover. Eyebolts installed in the frame enable the complete generator to be lifted with a conventional overhead hoist. A heavy steel wrapper cover of drip-proof construction encloses the frame assembly.

1.3.2 The generator stator core is constructed of one-piece steel laminations. The steel laminations are assembled under pressure to form the stator core. The assembled core is rigidly welded to the frame ribs. Heavily insulated stator coils of highest quality magnet copper are inserted in the stator slots. Stator core slots are lined with highest quality insulating material. The complete stator assembly is impregnated with electrical varnish and baked several times to ensure excellent bonding qualities, high dialectric strength, and maximum moisture resistance. Stator leads on most units are brought out to a convenient junction box located on the generator frame. The leads terminate in standard connection lugs or strap copper terminals for ease of connection to the load lines.

Katolight Service - Master Repair Manual - Page 501

1.3.3 The generator field poles are mounted on a large diameter shaft. Field coils of heavily insulated wire are machine wound directly onto poles with insulating varnish or the new "extra strength" epoxies applied between each layer. Damper windings, consisting of heavy copper bars imbedded in the poles are standard on Kato revolving field generators. Their purpose is to keep damping current losses low and limit increase of third harmonic voltage with increase of load. The damper windings also prevent "hunting" during parallel operation of generators. The enitre rotor is dipped and baked to form one complete, homogeneous mass.

1.3.4 A heavy duty rotating DC exciter is directly connected to the generator. The exciter field bolts to the generator endbell and the exciter armature slides into place on an extension of the generator shaft. The exciter armature is normally aligned and locked in place on the generator shaft by either a key or by aligning a lug on the exciter armature with a slot in the generator shaft. Final locking is accomplished by a retaining bolt and washer. Heavy duty exciter armature windings, commutator and brush rigging assure excellent performance of the exciter. The complete exciter is covered by a removable drip-proof cover.

1.3.5 Generator excitation voltage is fed from the exciter to the generator field through sliprings and brushes. Heavy duty construction of sliprings and brush rigging emsures maximum commutation and service life of the sliding contacts. Under normal operating conditions the only maintenance of the brush rigging normally required is keeping the sliprings, commutator and brushes clean, and replacing brushes when worn excessively.

1.3.6 KATO single and two bearing generators are designed with a self contained cooling system which circulates air through the machine. Ambient air is drawn into the machine through louvered openings by a large capacity blower. The warm air is exhausted through the screened opening enclosing the blower assembly.

1.3.7 Most KATO generators under 75 KW in size have "sealed" ball bearings which do not require periodic lubrication. Most KATO generators over 75 KW in size have grease fittings in the bearing housing and have bearings which should be periodically lubricated. Refer to Section 4, paragraphs 4.14 through 4.14.2.

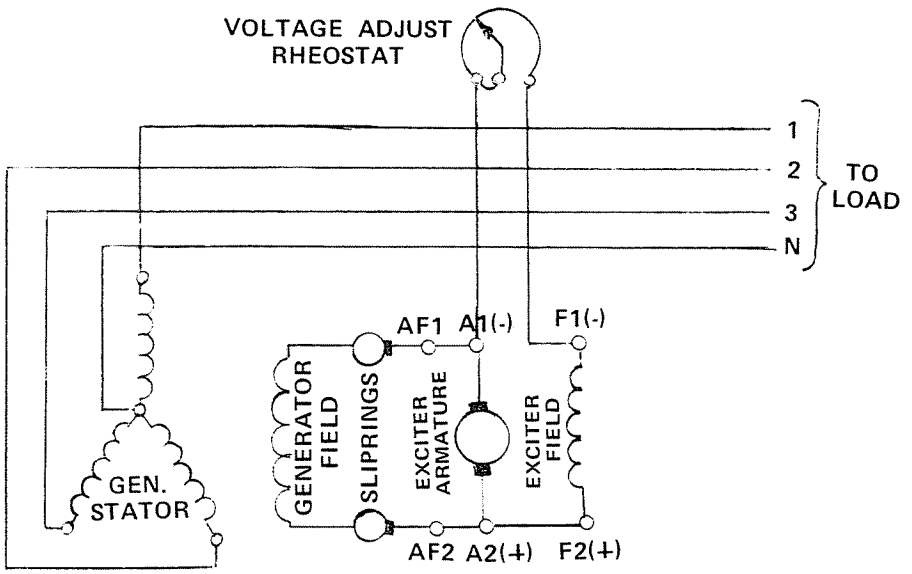

FIGURE 1-4 REVOLVING FIELD GENERATOR WITH DIRECT CONNECTED BRUSH TYPE DC EXCITER – VOLTAGE INHERENTLY REGULATED.

SECTION 2 INSTALLATION

2.1 RECEIVING INSPECTION

2.1.1 The generator is carefully packed and crated for shipment, and can withstand most shocks incurred during transit. Before accepting shipment from the transportation company examine the crating carefully to determine if any damage has occurred during shipment. Unpack the unit as described in paragraph 2.2 and then carefully examine the sheet metal frame cover and exciter cover for signs of damage. Remove the exciter cover and fan screen and examine the inside of the generator for signs of damage to windings, lead wires, and other internal parts. Inspect for loosely mounted components and the presence of moisture. Inspect to make certain foreign material such as crating nails, loose bolts, or packing material which may have fallen into the machine during unpacking are removed. On two-bearing machines turn the rotor by hand to make certain it rotates freely without binding. If damage is noted, determine the extent of damage and immediately notify the transportation company claims office and Kato Engineering Company. Be sure to give complete and accurate details when reporting damage.

2.1.2 If the generator is to be placed in storage repackage and crate the generator set. Recommended procedures for storage are contained in paragraph 2.2.

NOTE: **Single bearing generators are usually shipped with brushes raised in brush holders to prevent damage to brushes during shipment and installation. DO NOT LOWER BRUSHES IN BRUSH HOLDERS UNTIL INSTALLATION OF GENERATOR TO ENGINE IS COMPLETE.**

2.2 UNPACKING AND STORAGE

2.2.1 If the generator is received during cold weather, let the crated unit stabalize to room temperature before removing the protective crating and packing material. This precaution will minimize the condensation of moisture on coil surfaces, eliminating the possibilities of wet windings and insulating materials which could cause early malfunctions of the generator.

2.2.2 Unpack the generator with care to avoid damage to the unit. Move the generator to the mounting location by attaching an overhead hoist to the eye-bolts installed in the generator frame. Determine that the hoist, when used, is of sufficient strength to adequately support the weight of the generator. Hoist and hoist cables should have a rating of not less than 1½ times the weight of the generator.

CAUTION

ALWAYS MAKE CERTAIN EXTREME CARE IS TAKEN WHEN MOVING THE GENERATOR TO PREVENT ITS STRIKING OTHER OBJECTS OR PERSONNEL. NEVER APPLY A LIFTING FORCE TO STRUCTURAL POINTS OTHER THAN THOSE PROVIDED FOR THAT PURPOSE.

2.2.3 If the generator is not to be installed in its operating location as soon as received, it should be stored in a clean, dry area, not subject to sudden temperature or humidity changes. If possible, storage should be in an ambient temperature of approximately normal room temperature. Units which cannot be stored in a temperature and humidity controlled area and which are to be in storage for a period of longer than six months should be prepared for storage by installing desiccant bags under the exciter cover and inside the terminal box and vacuum sealing the unit in a covering of plastic or other material designed for that purpose. The unit should be adequately tagged to ensure that desiccant bags are removed before the unit is placed in operation.

2.3 LOCATION

2.3.1 The synchronous generator can be installed in a well ventilated area which affords sufficient accessibility for operation and maintenance of the unit and which allows a sufficient unobstructed flow of coolant air. Avoid locations which would subject the generator to excessive moisture, dust, steam or the funes from acids, alkalines or other corrosive chemicals. If such exposure cannot be avoided, establish a rigid periodic maintenance schedule. The adverse effect of excessive moisture can usually be eliminated or at least greatly lessened by the use of space or strip heaters.

2.3.2 The foundation or supports which mount the generator and prime mover must be rigid, level and of ample size and strength to support the weight of the generator and prime mover. Although a reinforced concrete foundation usually makes the best foundation for heavy machinery, the generator and prime mover may be placed on any concrete, steel or other structural material which will adequately support the weight of the unit. Bearing loads of structural materials can be obtained by referring to engineering handbooks.

Katolight Service - Master Repair Manual - Page 504

2.4 ASSEMBLING SINGLE BEARING GENERATOR TO ENGINE

2.4.1 The generator and engine should be mounted on a rigid steel base. Paragraph 2.4.2, steps (a) through (q) describe the major precautions and steps necessary to ensure satisfactory installation of the generator to the engine. They are listed in the order that the assembly work should be performed.

2.4.2 Slight differences exist between the various models and types of Kato Generators within the series described in this manual. Personnel assembling the generator to the engine must make certain that any assembly prodecures necessary to completely install the generator to the engine is done, even though some of the work which must be performed when assembling the generator to the engine may not be described in the following steps.

a. Before assembling generator to engine, remove exciter and generator covers and raise the exciter and generator brushes in their holders as shown in figure 2-1.

b. Before assembling generator to the engine, check to make certain generator bearing end clearance is sufficient. **GENERATOR BEARING END CLEARANCE SHOULD NOT BE LESS THAN: TOTAL ENGINE CRANKSHAFT AXIAL MOVEMENT + 1/16 in.**

NOTE

Generator shipped from factory with approximately 1/8 inch bearing end clearance.

c. Before starting to assemble the generator to the engine, mount the base of a dial indicator on the engine flywheel housing (bellhousing) and position the indicator finger on the drive disk recess of the flywheel as shown on figure 2-2. Set the dial indicator to zero. Turn the engine through one complete revolution. **TOTAL INDICATOR READING SHOULD NOT EXCEED .003-inch per EACH FOOT OF DIAMETER OF THE FLYWHEEL.** See TABLE 2-1.

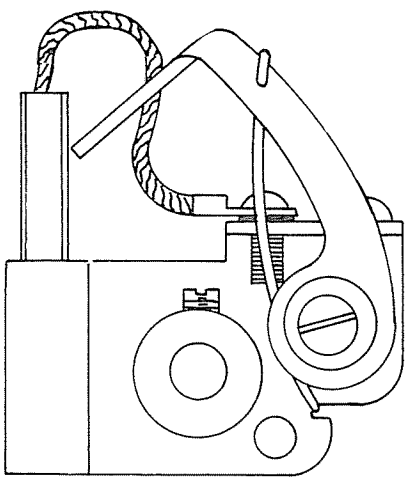

FIGURE 2-1 BRUSH RAISED IN BRUSH HOLDER.

If reading exceeds allowable limits excessive vibration could result. Contact the engine manufacturer for recommendations if runout exceeds suggested limits.

NOTE

The flywheel drive disk recess may have to be machined if runout is excessive. If the flywheel requires machining and it is not practical to remove the flywheel from the engine shaft, contact KATO Engineering Company, Parts and Service Department, requesting information pertaining to KATO tooling available on a rental basis, which will permit turning the flywheel without removing it from the engine.

d. Before starting to assemble the generator to the engine, mount the base of a dial indicator on the center of the flywheel and position the finger of the indicator on the machined surface of the flywheel housing (bellhousing) which bolts to the generator adapter. See figure 2-3. Set the dial indicator to zero. Turn the engine through one complete revolution. **TOTAL INDICATOR READING SHOULD NOT EXCEED .003-INCH PER EACH FOOT OF DIAMETER OF THE FLYWHEEL HOUSING.** See TABLE 2-1. If reading exceeds the allowable limit excessive vibration could result. Contact the engine manufacturer for recommendations if runout exceeds .003-inch per foot of diameter of the flywheel housing.

e. Before starting to assemble the generator to engine, measure the distance from the surface on the generator adapter that bolts to the engine flywheel housing (Dimension "Y", figure 2-4). Measure the distance from the machined surface on the engine flywheel housing to the bottom of the drive disk recess in the flywheel (Dimension "C", figure 2-5).

DIMENSION "C" MUST EQUAL "Y"

If the distance from the flywheel housing to drive disk recess "C" is more than the distance from the generator adapter to drive disks "Y", install additional spacers between the drive disks and the generator drive hub. If "Y" is more than "C" remove spacers located between the drive disks and generator drive hub.

f. Make certain drive disks "seat" in the drive disk recess.

WARNING

NEVER GRIND O.D. OF DRIVE DISKS AND NEVER ATTEMPT TO "DRILL OUT" HOLES IN DRIVE DISKS. IF DRIVE DISKS DO NOT FIT PROPERLY, ORDER NEW DRIVE DISKS. INCLUDE DIMENSIONAL DATA OF FLYWHEEL.

g. Use lock washers on all bolts used to secure generator to engine and base.

h. If the bolts that secure the drive disks to the flywheel cannot be installed due to insufficient clearance between fan and drive disks, it may be necessary to loosen and move fan.

NOTE

If bolts that secure the drive disks to the flywheel cannot be tightened with a socket or box wrench, using 1/4 - inch to 3/8 - inch long spacers inserted on the bolts as shown in figure 2-6 will increase the clearence between the bolt heads and the flywheel.

TABLE 2-1

FLYWHEEL DRIVE DISK RECESS		
Pilot Diameter	Nominal Clutch Dia.	Allowable Run Out (Total Indicator Reading)
6½	8.500	.002
7½	9.500	.002
8	10.375	.002
10	12.375	.003
11½	13.375	.003
14	18.375	.004
16	20.375	.005
18	22.500	.005
21	26.500	.006
24	28.875	.007

FLYWHEEL HOUSING		
SAE Housing Number	Housing Inside Dia.	Allowable Run Out (Total Indicator Reading)
6	10.500	.002
5	12.375	.003
4	14.250	.003
3	16.125	.004
2	17.625	.004
1	20.125	.005
½	23.000	.005
0	25.500	.006
00	31.000	.007

CAUTION

IF FAN IS MOVED, MAKE CERTAIN THAT BEFORE GENERATOR SET IS PLACED IN OPERATION FAN IS POSITIONED WITH ABOUT ½-INCH CLEARANCE BETWEEN FAN AND BAFFLE AND ALL FAN BOLTS ARE INSTALLED AND TIGHTENED.

i. Make certain generator mounting pads contact the base evenly and with equal pressure. Use of shims may be required.

j. After generator is assembled to the engine; but before installing the fan screen or placing generator set in operation, check run out of the generator shaft. Check run out by placing the base of a dial indicator on a generator frame rib and positioning the indicator finger on the generator shaft as shown in figure 2-7. Set dial indicator to zero. Turn generator through at least one revolution. TOTAL INDICATOR READING SHOULD NOT EXCEED .005 - INCH. See NOTE on page 7.

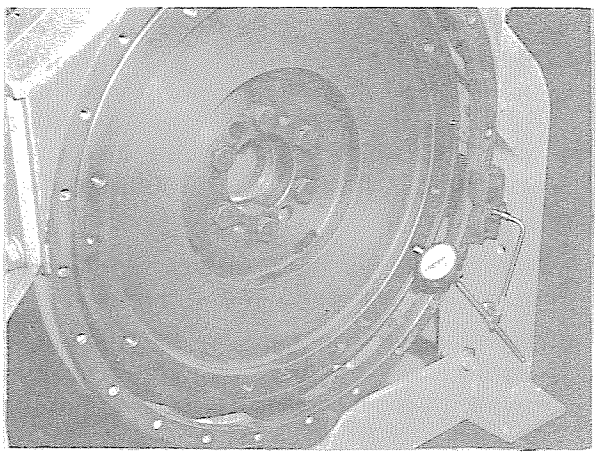

FIGURE 2-2 CHECKING ENGINE FLYWHEEL RUNOUT

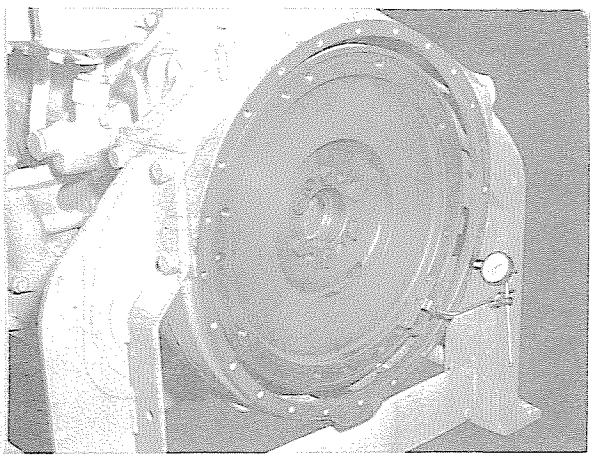

FIGURE 2-3 CHECKING ENGINE FLYWHEEL HOUSING RUNOUT

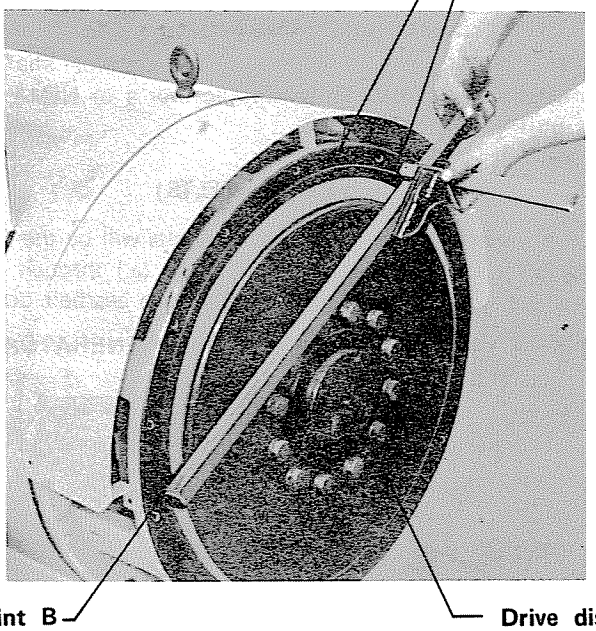
NOTE

Use inspection mirror to read indicator. It may be necessary to move fan out of the way. See CAUTION following step h.

k. After generator is assembled to engine, but before placing the generator set in operation, go back and make certain all bolts that secure the generator to the engine and the base are tight. Check to make certain generator fan is positioned with approximately ½-inch clearance between fan and fan baffle and check all fan bolts to make certain they are tight.

l. Before placing generator set in operation, visually inspect clearance between generator stationary and rotating parts.



Using a straight edge and depth gauge or machinists scale measure from a straight edge placed on the outside of the drive disks to the machined surface on the generator adapter which bolts to the engine flywheel housing (dimension "Y"). Place straight edge close to bolts which secure drive disks to drive hub.

For a more accurate measurement measure at point A and point B and divide by 2.

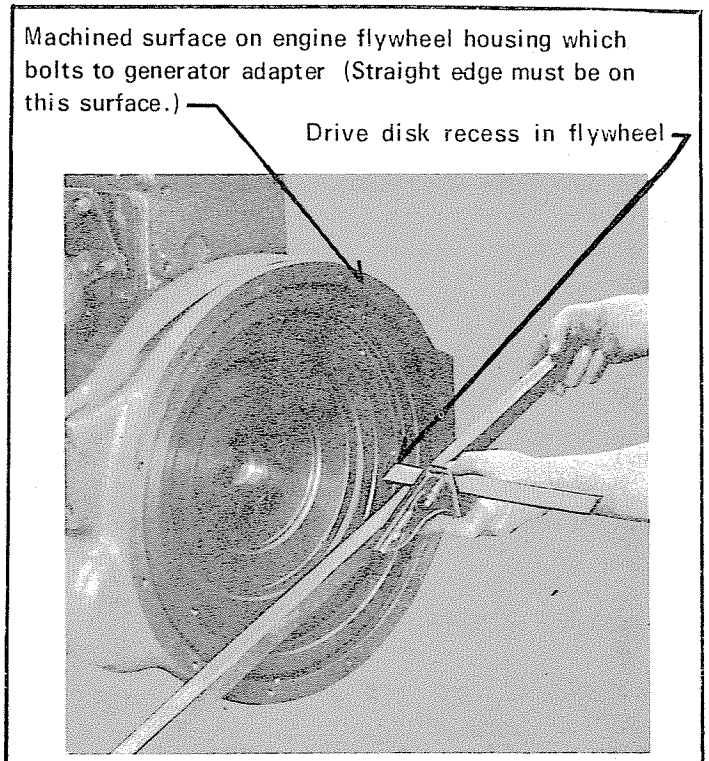
FIGURE 2-4 CHECKING SPACING FROM GENERATOR ADAPTER TO OUTSIDE OF DRIVE DISKS (DIM. "Y")

m. If the exciter armature is not installed, slide it completely onto generator shaft and install retaining bolt and washer.

CAUTION

IF EXCITER HAS AN ALIGNING KEY MAKE CERTAIN KEY IS IN PLACE BEFORE INSTALLING EXCITER ARMATURE.

n. Lower exciter and generator brushes in brush holders. Make certain they are seated and centered on the commutator and the collector rings (slip rings). Make certain exciter brushes and brush holders are clear of commutator riser.



Using a straight edge and depth gauge or machinists scale measure from the drive disk recess in flywheel to straight edge placed across the machined surface on the engine flywheel housing (Dimension "C").

NOTE

If the flywheel housing has a pilot which extends beyond the bolting surface on the flywheel housing and the straight edge is layed across the pilot, subtract the distance from the pilot to the bolting surface of flywheel housing.

FIGURE 2-5 CHECKING SPACING FROM BOLTING SURFACE OF ENGINE FLYWHEEL HOUSING TO BOTTOM OF THE DRIVE DISK RECESS IN FLYWHEEL (DIM. "C")

o. Before placing generator set in operation, turn engine through several revolutions, but do not permit engine to start. Visually inspect clearance between generator stationary and rotating parts. Check alignment of the exciter armature with exciter field poles. Listen for unusual noises such as produced by parts rubbing together.

p. When assembly has been satisfactorily completed and inspected, install covers and guards.

q. Start and stop the generator set several times. Listen for unusual noises, vibration or any other abnormal conditions. See Section 3, paragraphs 3.1 and 3.2.

2.5 SELECTION OF DRIVES FOR TWO - BEARING GENERATOR

2.5.1 Satisfactory generator operation will depend upon intelligent selection of drive couplings. In general, solid couplings are not recommended except when the generator and prime mover frames are directly connected and belt drives should not be used when belt speed exceeds 5000 feet per minute.

2.6 BELT DRIVES - GENERAL INFORMATION

2.6.1 Proper alignment and tightness of belt drives is essential. Improper alignment and belt tightness will increase belt wear as well as increase bearing loads and vibration. Select belt drive in accordance with belt manufacturer's specifications. Make certain generator and prime mover are rigidly mounted. In general belt drives are not recommended when belt speed exceeds 5000 feet per minute.

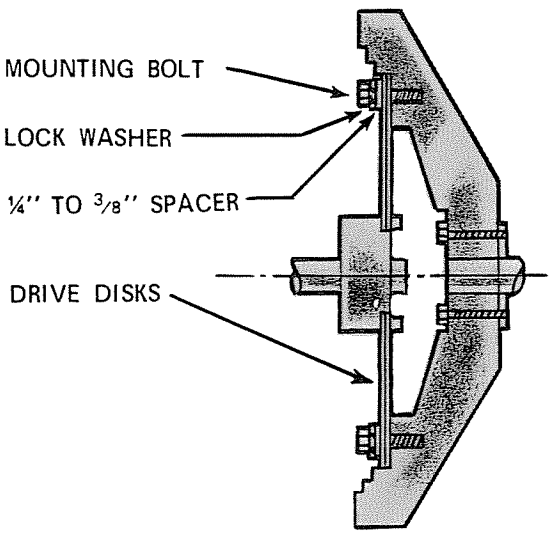


FIGURE 2-6 TYPICAL DRIVE DISK TO FLYWHEEL INSTALLATION.

2.7 V-BELT

2.7.1 Use only matched belt sets and avoid minimum pitch sheaves and belts. Follow the V-belt manufacturer's specifications or NEMA limits for sheave pitch.

2.7.2 Make certain the shaft axis of the prime mover and generator are paralled. Belts must enter and leave sheaves with no side bending. Tighten just enough to prevent slippage at full load. Never grease or use belt dressing on belts.

2.8 FLAT BELT

2.8.1 Selection of belts and pulleys of ample width will reduce amount of tension required to prevent slippage at full load. Lower belt tension reduces bearing loads and belt wear.

2.8.2 Position the pulleys so crowns are in the same plane. Make certain motors and generator shafts are paralleled. Observe belt manufacturer's or NEMA limits for pulley sizes.

2.9 GEAR BELTS (TIMING BELTS)

2.9.1 In general, installation of gearbelts will be the same as for flat belts. The precautions listed in (a.) through (e.) on page 9 should be taken when installing a gearbelt drive.

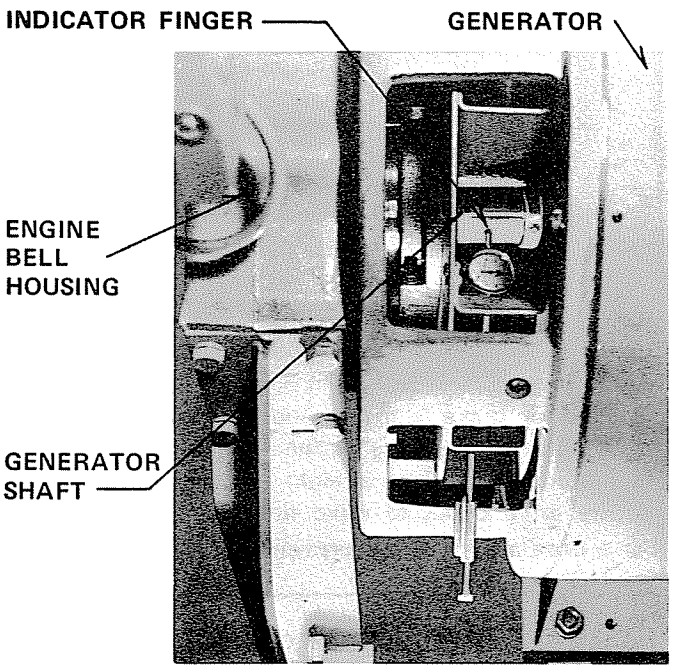

FIGURE 2-7 CHECKING GENERATOR SHAFT RUNOUT

Katolight Service - Master Repair Manual - Page 508

a. Gearbelts should be installed with snug fit, neither too tight or too loose. High initial tension is not necessary but when torque is unusually high a loose belt may "jump grooves". If the belt "jumps the grooves" the tension should be increased gradually until satisfactory operation is attained.

b. Be sure that shafts are parallel and pulleys are in alignment. On a long center drive, because of the tendency of the belt to run against one flange, it is sometimes advisable to offset the driven pulley to compensate.

c. On a long center drive, it is imperative that belt sag is not enough to permit teeth in the slack side to engage the teeth at the tight side.

d. It is important that both prime mover and generator are mounted rigidly to prevent variation in belt tension.

e. Although belt tension requires little attention after initial installation, provision should be made for some center distance adjustment for ease in installing and removing belt. Do not force belt over flange of pulley.

2.10 GEAR AND FLEXIBLE COUPLINGS GENERAL INFORMATION

2.10.1 When these drives are used instead of belt drives, the prime mover and generator shafts must be carefully aligned. The motor and generator must be firmly mounted to a rigid base to prevent misalignment of the unit shafts during operation. Excessive misalignment could cause vibration, noisy operation, excessive coupling or gear wear or premature bearing failure. Procedures for aligning gear and flexible couplings are contained on the following page.

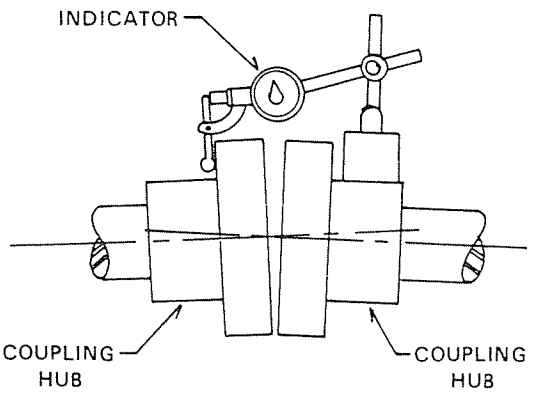

FIGURE 2-8 TESTING ANGULAR ALIGNMENT OF MOTOR AND GENERATOR SHAFTS

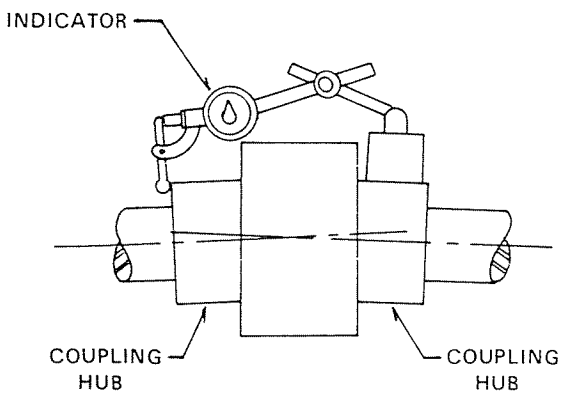

FIGURE 2-9 TESTING ANGULAR ALIGNMENT OF MOTOR AND GENERATOR SHAFTS FOLLOWING COUPLING INSTALLATION

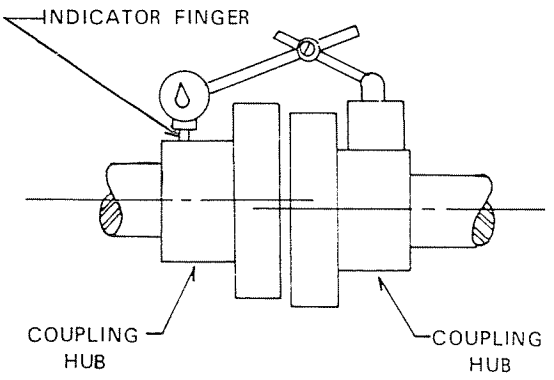

FIGURE 2-10 TESTING PARALLEL ALIGNMENT OF MOTOR AND GENERATOR SHAFTS

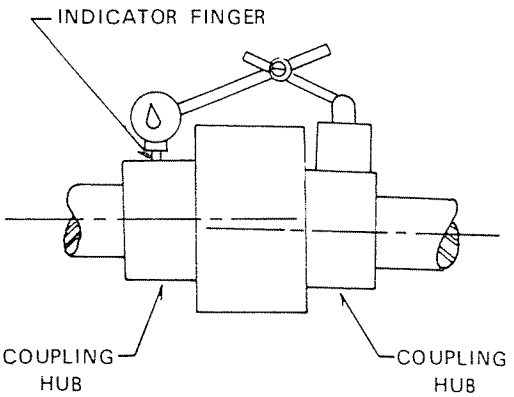

FIGURE 2-11 TESTING PARALLEL ALIGNMENT OF MOTOR AND GENERATOR SHAFTS FOLLOWING COUPLING INSTALLATION

2.11 GEAR DRIVE

2.11.1 Accurate alignment and rigid mounting are essential for satisfactory operation with gear drives. Pitch diameter and width should not be outside recommended NEMA limits. Avoid coupling which will impose excessive thrust on bearings.

2.11.2 In all cases, gear teeth must be centered with each other. Gear faces must be parallel and correct shaft center distance maintained. Gear teeth must fully engage to a depth giving approximately .002 inch maximum backlash. Avoid engagement of teeth so deep that they will bind or deflect.

2.11.3 Test for proper alignment by rotating shafts by hand. Check for backlash through at least one revolution of the shafts. Check backlash and gear face parallelism after tightening mounting bolts. Install or remove shims from under mounting feet to bring gear faces parallel.

2.12 INSTALLATION AND ALIGNMENT OF FLEXIBLE COUPLED DRIVES

2.12.1 The procedures outlined are for aligning flexible coupled drives. Follow the tolerances specified by the coupling manufacturer when less than described in this manual.

2.12.2 Install coupling hubs on generator and drive shafts in accordance with the installation procedures supplied by the manufacturer of the coupling. Then check for angular misalignment by scribing a reference mark on the coupling hub at the button or finger of the indicator to mark its position on the hub. Rotate both shafts simultaneously, keeping the finger or button of the indicator at the reference marks on the coupling hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to figure 2-8 for test setup.

ANGULAR MISALIGNMENT OF THE SHAFTS MUST NOT EXCEED .001 INCH FOR EACH INCH OF RADIUS OF THE COUPLING HUB, TOTAL INDICATOR READING.

2.12.3 If angular misalignment is excessive, loosen motor and generator mounting bolts and place slotted shims under motor and generator mounting pads, as necessary, to correct alignment. Re-check alignment. Install or remove shims from under the mounting pads until aligned.

NOTE: If the motor generator set is moved to a new location, make test setup with coupling installed as shown in figure 2-9 and then rotate shafts and check alignment as described in paragraph 2.12.2.

2.12.4 Check for parallel shaft (run-out) alignment by scribing a reference mark on the ground or machine diameter of the coupling hub at the finger or button of the indicator. Rotate both shafts simultaneously, keeping the button or finger of the indicator at the reference mark on the hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to figure 2-10 for test setup.

TOTAL RUN-OUT BETWEEN HUBS SHOULD NOT EXCEED .002 OF AN INCH.

2.12.5 When run-out between hubs is excessive, install or remove shims from under each of the motor or generator mounting pads; then re-check alignment, Add or remove shims until shafts are parallel. Tighten motor and generator mounting bolts following angular and run-out alignment. Check base mounting bolts for tightness. Re-check alignment before installing coupling.

NOTE: If the motor generator set is moved to a new location check for parallel alignment by making test setup as shown in figure 2-11 and then rotate shafts and check alignment as described in paragraph 2.12.4.

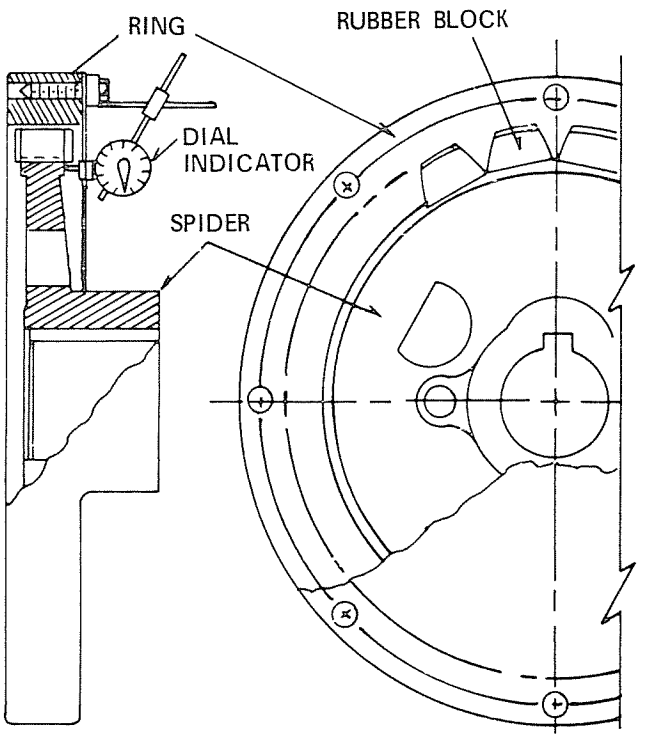

FIGURE 2-12 CHECKING ALIGNMENT OF TWIN DISC COUPLING.

Katolight Service - Master Repair Manual - Page 510

2.13 FLYWHEEL AND TWIN DISC CLUTCH COUPLING

2.13.1 A flywheel and twin disc clutch coupling provide a satisfactory coupling for motor generator sets operating with shaft speeds not in excess of 3760 RPM. The coupling should be parallel between the spider and the rings. Align within .03 inch total indicator reading between spider and ring by installing or removing shims, as necessary, from under motor or generator mounting pads. See figure 2-12.

2.14 INSTALLATION OF KATO VIBRATION DAMPENERS (KATO BASE MOUNTING FEET)

2.14.1 When motors or motor generator sets are installed in areas such as office buildings where noise or vibration would be a nuisance, these undesirable effects can usually be eliminated or greatly reduced by installing vibration dampeners.

2.14.2 KATO base mounting feet when properly installed provide a means of easily leveling generator sets as well as providing "vibration dampening". Install KATO base mounting feet as shown on figures 2-13 and 2-14.

Level unit by loosening Base Foot mounting bolts and then sliding base foot in elongated slots.

Anchor to foundation with anchor bolt. Use KATO "VIBRATION ISOLATORS" to provide vibration isolation.

DO NOT TIGHTEN ANCHOR BOLT NUTS TO TIGHTLY. COMPRESSION OF VIBRATION ISOLATOR AND NEOPRENE PAD WILL ELIMINATE THEIR EFFECTIVENESS.

2.15 VIBRATION

2.15.1 After alignment of motor generator set has been completed, run unit at no load and check for excessive vibration (see operation instructions, section 3). If vibration is excessive loosen one motor mounting bolt slightly and if vibration decreases, add shims until retightening of bolt reduces or eliminates vibration. Repeat in turn for all motor mounting bolts.

2.15.2 When vibration and alignment of motor are within limits, run motor generator set at low load and check again for vibration. If excessive, add shims under generator mounting pads in same manner as for the motor. Re-check alignment after any change in shims to control vibration.

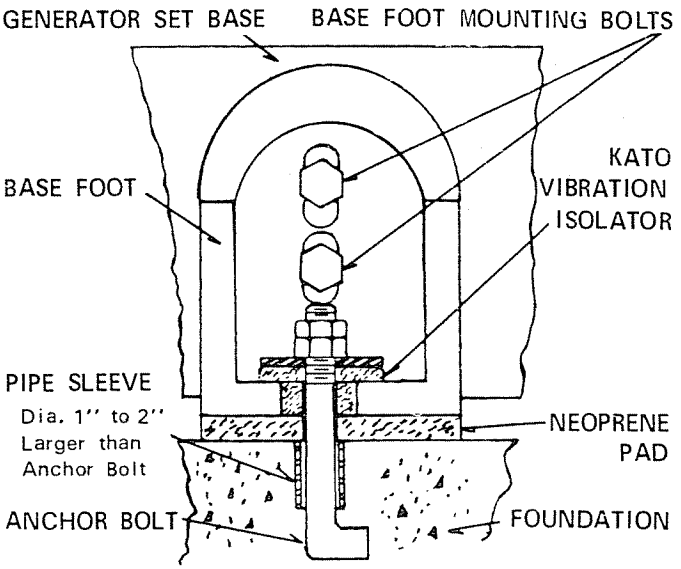

FIGURE 2-13 KATO BASE FOOT VIBRATION DAMPENERS.

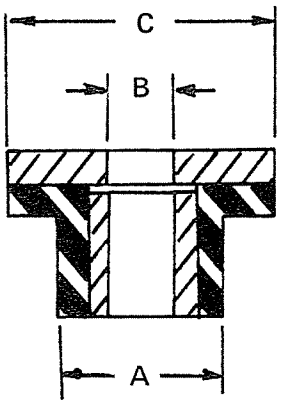

Part Number	A	B	C
158-00007-01 For 3/8" mtg. bolt Base Foot hole 1-1/32"	1-1/32"	.385	1-3/4"
158-00008-01 For 1/2" mtg. bolt Base Foot hole 1-7/32"	1-7/32"	33/64"	2"
158-00009-01 For 3/4" mtg. bolt Base Foot hole 1-1/2"	1-1/2"	49/64	3"

FIGURE 2-14 KATO VIBRATION ISOLATORS

2.16 DOWELING

2.16.1 Doweling generator sets will prevent movement of the units during operation should the mounting bolts loosen slightly. Install dowels as follows:

a. Check the alignment after the generator set has been in operation about 40 hours. Correct alignment if not satisfactory (refer to preceding paragraphs).

b. Through opposite generator pads drill holes through and into the base. Holes should have a diameter slightly smaller than the dowel pin.

c. Ream the holes to the proper diameter for the pins, clean out chips and then install pins.

d. Repeat procedure for doweling of motor.

NOTE: Dowel prime movers (engine or motor) manufactured by others than Kato Engineering Company in accordance with the instructions supplied by the manufacturer of the prime mover.

2.17 ELECTRICAL CONNECTIONS

2.17.1 Before connecting the generator to the electrical power load, check nameplate for the electrical characteristics and connect the generator exactly as shown in the connection diagrams. Refer to National Electrical Code and applicable local regulations for miminum specifications for wire size, conduit and protective devices.

2.18 PROTECTIVE DEVICES

2.18.1 Engine driven sets must be protected with adequate engine governors and protected against excessive overspeed. Refer to National Electrical Code and local electrical codes for minimum electrical requirements for the generator set.

2.18.2 The output to the load of the generator should always be protected with an overload protection device such as a circuit breaker or fuses. Size fuses and circuit breakers in accordance with National Electrical and Local Codes.

SECTION 3 OPERATION

3.1 PRE-OPERATION EQUIPMENT CHECK

3.1.1 After the generator and control equipment is completely installed and wired, but before operating the unit for the first time, perform a check of the equipment as follows:

a. If the generator windings have become wet, test winding insulation resistance and dry out windings before placing the unit in operation. Refer to the procedures for testing winding insulation resistance and the procedures for drying windings contained in Section 4 of this manual. Generators being placed in operation after being subjected to very low temperatures should be slowly warmed to prevent condensation.

b. See paragraph 4.14. If unit has bearings which require lubrication, grease bearings.

c. Check all interconnecting wiring against the connection diagrams supplied with the generator set.

d. Make certain brushes are seated and centered on the generator sliprings.

e. Inspect to see that satisfactory clearance exists between generator rotating and stationary parts. On two bearing generators rotate shaft by hand to make certain it turns freely.

f. Make certain no foreign objects are lodged in the generator. Remove all tools and shop cloth from the vicinity of the equipment.

3.2 INITIAL START

3.2.1 After installation is complete and the checks listed in paragraph 3.1 have been completed make an initial start and operational checkout of the equipment as listed in the following general instructions:

a. Open the OUTPUT CIRCUIT BREAKER to disconnect the generator from the load.

b. Adjust excitation controls to supply minimum excitation to the generator field. (Normally, adjustment of field rheostats should be to full resistance - full counterclock-wise position or if variable transformer is used transformer should be adjusted to minimum voltage position).

c. Start the generator set in accordance with the prime mover manufacturer's specifications.

d. Stop generator set. Check rotation as unit slows to stop. On motor driven generator sets, if rotation is not correct, reverse incoming power leads. On three phase motors, reverse any two incoming lines (except the neutral line).

e. Start and stop generator set several times. Observe any unusual conditions such as excessive noise or vibration. Allow sufficient time between starts for cooling.

f. When operation is satisfactory to this point, adjust voltage adjust rheostat (normally to approximately the midpoint position). Start generator and bring up to rated speed. Turn voltage adjust rheostat to point where desired output voltage is obtained.

g. Close output circuit breaker and apply a light load. Adjust voltage adjust rheostat until desired output voltage is obtained.

h. Slowly increase load to rated power factor full load. Adjust rheostat as necessary to obtain desired output voltage.

i. When an automatic voltage regulator is incorporated, check voltage regulation by applying the rated power factor load, and then checking the generator terminal voltage. Check voltage regulation. Refer to regulator manufacturer's operating instructions.

j. During operation, observe the generator at regular intervals so that any abnormal conditions can be corrected before serious damage occurs.

k. Check current on each line. Use a clip-on ammeter if an ammeter is not incorporated in generator set.

l. Check line-to-line and line-to-neutral voltages.

m. Shut down unit in accordance with the operating instructions supplied by the manufacturer of the prime mover.

3.3 SINGLE GENERATOR OPERATING INSTRUCTIONS

3.3.1 If the generator windings have become wet, test winding insulation resistance and dry out windings before operating the generator set. Refer to the procedures for testing winding insulation and the procedures for drying windings contained in Section 4 of this manual. Operate generator as described in paragraph 3.3.2.

Katolight Service - Master Repair Manual - Page 513

3.3.2 Start and operate the generator set in accordance with the following general instructions:

a. When voltage adjust rheostats have been previously adjusted to provide the desired output voltage, no adjustment should be required before placing the generator set in operation.

b. Start the generator set in accordance with the operating instructions supplied by the manufacturer of the prime mover. Bring up to rated speed.

c. Turn voltage adjust rheostat to point where desired generator output voltage is indicated on voltmeter. Apply load. Check output voltage, if not of desired value re-adjust the voltage adjust rheostat or, if used, variable transformer.

d. When an automatic voltage regulator is incorporated in the generator set, check voltage regulation.

e. During operation, observe the generator at regular intervals so that any abnormal conditions can be discovered and corrected.

f. When the generator set is operated as a standby unit open the OUTPUT CIRCUIT BREAKER before shutdown of the generator set.

g. Stop the generator in accordance with the instructions supplied by the manufacturer of the prime mover.

3.4 OPERATION OF STANDBY GENERATOR

3.4.1 Make certain OUTPUT CIRCUIT BREAKER of the primary power source is open before starting the STANDBY UNIT. Operate the generator set as described in paragraph 3.3. Following shutdown of the STANDBY UNIT, make certain OUTPUT CIRCUIT BREAKER is actuated to the OPEN position.

3.5 OPERATING INSTRUCTIONS FOR PARALLEL OPERATION OF GENERATORS

3.5.1 When operating two or more generators connected in parallel, open output circuit breaker and start each generator as described in steps (a) through (e) of paragraph 3.3.2. Make certain that the output voltage of each machine is properly adjusted to the system bus voltage.

CAUTION

DO NOT CLOSE THE LOAD CIRCUIT BREAKERS UNTIL THE GENERATORS HAVE BEEN CHECKED FOR PROPER PHASE ROTATION AND ADJUSTED FOR SYNCHRONIZATION AS DETAILED IN THE FOLLOWING PARAGRAPHS.

3.6 PHASE ROTATION

3.6.1 Before placing two or more three-phase generators in parallel, make certain the generators have the same phase rotation. This can be accomplished by connecting a three phase induction motor to each of the generators and checking the rotation of the motor. Care must be taken to make certain motor terminals are connected to the corresponding generator or bus terminals for each test. Phase rotation will be the same if the motor rotates in the same direction when connected to each generator.

3.6.2 If the motor rotates in the wrong direction when connected to one of the generators, reverse any two of the three generator leads (except neutral when used). Recheck motor rotation and continue checks until the induction motor rotates in the correct direction.

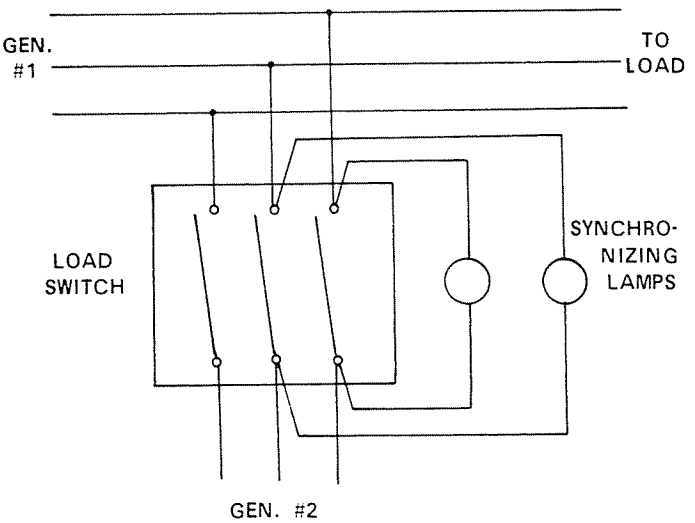

FIGURE 3-1. SYNCHRONIZING PARALLELED GENERATORS USING TEST LAMPS

WARNING

EXERCISE EXTREME CAUTION WHEN USING THIS METHOD OF SYNCHRONIZING GENERATORS TO AVOID EXPOSURE TO DANGEROUS VOLTAGES.

3.7 SYNCHRONIZING PARALLELED GENERATORS

3.7.1 Do not attempt to parallel generators until each machine to be paralleled has been checked for proper phase rotation and that each generator is adjusted for the required system voltage with the line switch open.

3.7.2 If a synchroscope is not available, generators can be synchronized by using incandescent lamps connected in the load circuit as shown in figure 3-1. Make certain that the total voltage rating of the series lamps equals the voltage rating of the generator.

3.7.3 Synchronize the generators by varying the speed of the incoming generator until fluctuation of the lamps is very slow. When the lamps are dark close the line switch. Care must be taken to close the line switch at the instant the lamps are dark .

3.8 DIVISION OF POWER LOAD AMONG PARALLELED GENERATORS

3.8.1 Adjust the engine governors in accordance with the engine manufacturer's instructions. Division of kilowatt or actual power load among generators operating in parallel is practically independent of generator excitation. Do not attempt to vary the amount of kilowatt load among paralleled generators by making adjustments to the voltage regulator.

3.9 DIVISION OF REACTIVE KVA AMONG PARALLELED GENERATORS

3.9.1 Division of reactive KVA among paralleled generators depends upon generator excitation. Methods of correcting the excitation of individual generators, should they take more or less than their share of the reactive KVA, are the addition of cross-current compensation or voltage-droop controls to the voltage regulator circuit.

3.9.2 The cross current or voltage droop rheostat should usually be set so that there is just enough resistance in the circuit to give stable operation of the generators under reactive KVA load conditions .

3.9.3 Place generator in operation, apply lagging power factor load, and check voltage droop. Maximum voltage droop from no load to full load is obtained with full voltage-droop resistance. A droop of 4% is frequently employed. Adjust each generator to be paralleled for identical droop characteristics.

3.9.4 Bring all generators up to correct speed and adjust all output voltages to identical values. Synchronize and parallel generators. Load the paralleled generators and check for satisfactory division of load currents. Correct by adjusting voltage-adjust rheostats and the droop-control resistors.

SECTION 4 MAINTENANCE

4.1 PREVENTIVE MAINTENANCE

4.1.1 Preventive maintenance is the practice of inspecting the generator set, cleaning the generator set, and eliminating minor disorders before they become serious. A routine regular preventive maintenance program practiced conscientiously will ensure peak performance, lengthen the life of the generator, and eliminate or at least greatly reduce breakdown time.

4.1.2 The quarterly preventive maintenance schedule described in TABLE 4-1 is enclosed as a guide for establishing a preventive maintenance program for generators operating under standard conditions. The specific operating conditions should be analyzed by the user of the equipment and a preventive maintenance program established accordingly. When preventive maintenance inspection determines cleaning is necessary, clean the generator and controls as described in paragraph 4.2.1.

4.2 CLEANING

4.2.1 When inspection determines cleaning is necessary, clean the generator and controls as follows:

a. Wipe loose dirt from exterior painted surfaces of generator and, when incorporated, the generator control panel assembly (controller) with a clean lint free cloth. Remove stubborn accumulations of dirt with an approved detergent or solvent. Clean all ventilating ports with a vacuum cleaner or filtered compressed air at a pressure of from 25 to 40 psi.

WARNING

OBSERVE PRECAUTIONS SPECIFIED BY THE MANUFACTURER OF THE SOLVENT BEING USED.

b. Clean inside of generator with a vacuum cleaner or use dry filtered compressed air at a pressure of from 25 to 40 psi. Remove stubborn accumulations of dirt and grease from windings with naptha.

WARNING

EXERCISE EXTREME CARE WHEN USING NAPTHA. USE ONLY IN WELL VENTILATED AREAS, AWAY FROM FLAME AND SPARKS .

c. Clean electrical contacts such as relay contacts, switch contacts, and terminals with an approved contact cleaner. **DO NOT FILE CONTACTS.**

d. Clean brushes and brushholders with lint free cloth. See paragraph 4.7, "Maintenance of Brushes, Brush Holders, and Sliprings".

TABLE 4-1

QUARTERLY PREVENTIVE MAINTENANCE SCHEDULE
1. If generator has bearings which require lubrication (grease fittings on generator), lubricate bearings at intervals and amounts shown on lubrication plate attached to generator.
2. Inspect lead wires and control device wiring for cracked insulation and loose terminals.
3. Inspect control equipment for loose mounting hardware.
4. Inspect control devices for accumulation of dust, moisture and other foreign matter.
5. Clean the outside of the generator assembly and ventilating screens. When dust or moisture is excessive, clean and/or dry the inside of the generator assembly.
6. Inspect brushes, brush holders, sliprings and commutator for satisfactory condition.
7. With unit running, check control devices and meters for correct adjustment and operation.
8. With unit running, observe any unusual noise or vibration. Refer to trouble shooting chart for possible causes of noise and vibration.

4.3 WINDINGS - PROTECTION

4.3.1 Generators operating intermittently in very damp locations should be protected with space heaters. Generators being placed in operation after being subjected to very low temperatures should be slowly warmed to prevent excessive condensation. Winding resistance should be checked before placing the generator in operation if the unit was subjected to an extremely damp environment.

4.4 INSULATION RESISTANCE TEST

4.4.1 A hand cranked megger of not over 500 volts is a convenient and safe method of testing insulation resistance. The formula contained on the following page is an accepted standard for measuring insulation resistance of stator windings.

Katolight Service - Master Repair Manual - Page 516

Winding insulation resistance measured at 500 VDC after one minute should not be less than:

$$\text{Resistance in megohms} = \frac{\text{Rated Voltage of Machine} + 1000}{1000}$$

The above formula is satisfactory for most checks. For more information see "Recommended Practice for Insulation Resistance Testing AC Rotating Machinery", AIEE Standard No. 43.

4.5 DRYING WINDINGS

4.5.1 If the insulation fails to meet the test standards, the generator may be dried out by heat from a warm air oven, heat lamps, or strip heaters. The temperature should not exceed 75°C. (167°F.) Another method which can usually be used to dry windings is by application of internal heat as described in paragraph 4.5.2.

WARNING

WHEN OVEN DRYING, USE A FORCED AIR CIRCULATION OVEN, NOT A RADIANT TYPE. RADIANT TYPE OVEN WOULD OVERHEAT SOME GENERATOR PARTS BEFORE REMOTE PARTS REACHED A SATISFACTORY TEMPERATURE.

4.5.2 Drying the generator winding insulation by the application of internal heat consists of operating the generator as described in the following procedure.

a. Check for excessive accumulation (pockets) of water on windings. Dry as much as possible with compressed air before applying internal heat.

b. In one of the stator leads, insert an ammeter of sufficient range to read full-load generator current.

c. Connect all stator lead terminals together to short circuit the stator windings.

d. If a voltage regulator is incorporated, disconnect the regulator incoming and output leads and connect a variable source of DC power to the exciter field leads.

CAUTION

USE A VARIABLE RESISTOR OR RHEOSTAT IN THE INPUT CIRCUIT TO THE EXCITER FIELD TO LIMIT GENERATOR CURRENT TO EQUAL TO OR LESS THAN RATED VALUE.

e. Operate the generator at normal speed. Supply just enough excitation to cause rated current to flow in the generator stator windings.

f. Operate for sufficient time to ensure thorough drying of the windings. This can be determined by stopping the generator periodically and checking the insulation resistance of the windings. Insulation resistance checks at one-hour intervals are suggested. Terminate the drying-out process when measured resistance is within test standards (paragraph 4.4) and shows little change over a two to four hour period of operation.

4.6 STATOR WINDING SHORT CIRCUIT TEST

4.6.1 Use an inside-type growler and test each coil in the stator. Position the growler in the stator and hold a thin metal strip, similar to a hacksaw blade, parallel to the core slots. Energize the growler and explore the core surfaces approximately 1 pole distance on each side of the growler. Continue testing 1 core slot at a time until all coils are tested. If the winding is shorted, the metal strip will vibrate when held over the slot containing the faulty coil.

4.7 MAINTENANCE OF BRUSHES, BRUSH HOLDERS, SLIPRINGS AND COMMUTATORS

4.7.1 Brushes, brush holders, sliprings and commutators should be inspected and cleaned periodically.

4.7.2 Dirty brush holders, commutators, sliprings and brushes or brushes which are not properly "seated", or pitted sliprings will cause excessive brush sparking and poor commutation. Brushes can be raised in their holders for inspection or sanding of the sliprings or commutator as shown in figure 4-1.

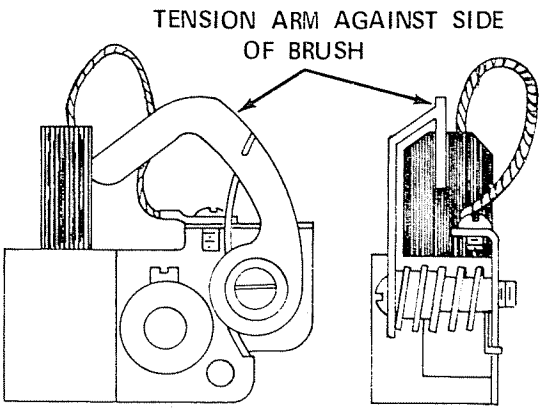

FIGURE 4-1 BRUSH RAISED IN BRUSH HOLDER.

4.8 REPLACING BRUSHES AND ADJUSTING BRUSH SPRING TENSION

4.8.1 Replace brushes when worn excessively. Make certain brush is replaced before tension arm rests on brush holder. When replacing brushes, it is most important that they are properly "seated" to the contour of the sliprings and free to move in the brush holders.

NOTE: **Always order replacement brushes of the same size and of an equivalent grade or type as were installed at the factory. Order by part number including the type and serial number of the generator.**

4.8.2 Nominal spring tension should be approximately 3 lbs./sq. in. of brush surface. Spring pressure within a range of from 2½ to 4 lbs./sq. in. of brush surface is normally acceptable.

4.9 SEATING BRUSHES

4.9.1 To properly seat brushes, lift all the brushes in their holders. Insert a strip of (No. 00) sandpaper between the brush and the slipring or commutator with the abrasive side toward the brush. Lower one of the brushes in the holder. With the brush in the holder and under pressure draw the sandpaper in the direction of rotation of the generator, keeping the sandpaper close to the contour of the sliprings or commutator. Lift the brush to release pressure before returning the sandpaper for the next stroke. Sand until at least 80% of the brush surface is in contact with the slipring or commutator. Sand each of the remaining brushes one at a time as described above.

4.9.2 Check for proper "seating" by running the machine at no load minimum excitation, and observe the area of bare sliprings or commutator polished by the brushes. Reseating of brushes is required when brushes are replaced, or the sliprings or commutator are resurfaced, or when excessive brush sparking is evident. Seat brushes on sliprings or commutator as described above.

WARNING
NEVER USE EMERY CLOTH TO SEAT BRUSHES

4.10 TURNING SLIPRINGS

4.10.1 When sliprings become too deeply pitted or grooved to be cleaned with sandpaper, the sliprings should be turned. Do not remove more material than is necessary to remove grooves or pitted areas from the slipring surface.

4.11 SANDING COMMUTATOR

4.11.1 Lift all brushes in their holders, install a strip of sandpaper with the abrasive side against the commutator. Using a hardwood block which has the same contour as the commutator surface, press the sandpaper surface against the commutator surface. Run the commutator at high speed while moving the block back and forth along the commutator surface parallel to the shaft.

4.12 TURNING COMMUTATORS

4.12.1 When the commutator is too deeply grooved or pitted to be cleaned with sandpaper, the armature must be mounted in a lathe and the commutator turned down. Make certain it is centered in the lathe.

4.12.2 Turn the commutator, removing only as much material as is necessary to remove grooves or pitted areas from the commutator surface. After turning, undercut the mica segments.

NOTE
IF COMMUTATOR IS NOT CONCENTRIC WITH THE TRUE SHAFT CENTER THE BRUSHES WILL BE FORCED TO MOVE IN THEIR HOLDERS TO CONFORM TO THE ECCENTRICITY OF THE COMMUTATOR WHICH WILL RESULT IN EXCESSIVE BRUSH WEAR AND SPARKING.

4.13 UNDERCUTTING COMMUTATOR

4.13.1 The commutator may be undercut by using either a square or "V" undercutting tool.

4.13.2 When a square undercutting tool is used, it should be slightly wider than the mica and well centered so that the mica fin as shown at (C), figure 4-2, page 19, is not left. Remove edges as shown at (A) by beveling as shown at (B).

4.13.3 When a "V" undercutting tool is used, the tool should be slightly wider than the mica to provide the bevel as shown at (E), figure 4-2, page 19. The mica fin shown at (D) will result if the undercutting is not deep enough. If the tool is not well centered a fin as shown at (F) will be the result. Always make certain the undercutting tool is centered and cuts deep enough to prevent these undesirable results.

Katolight Service - Master Repair Manual - Page 518

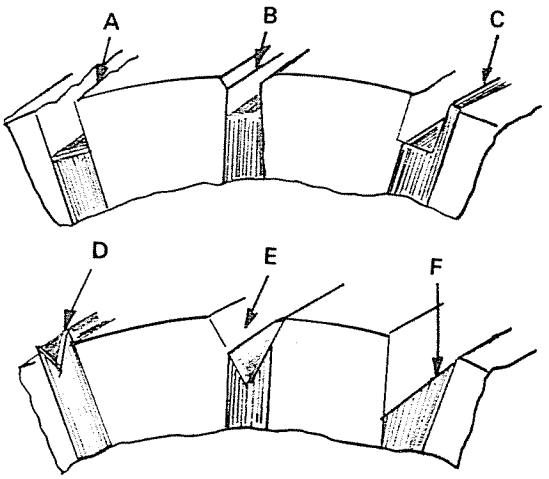

FIGURE 4-2 UNDERCUT COMMUTATOR

4.14 BEARINGS

4.14.1 The bearings are of the factory lubricated sealed or shielded cartridge ball bearing type on most KATO generators with rating under 75 KW. Sealed or shielded ball bearings do not require periodic replenishment of lubricating grease.

4.14.2 **Most Kato generators with ratings over 75 KW have ball bearings which should be periodically lubricated.**

Grease fittings are incorporated on Kato generators that have ball bearings which require periodic lubrication. A relief valve is generally installed in the drain ports on these machines.

Replenish grease at intervals and amounts listed on lubrication data plate attached to the generator.

DO NOT OVERFILL! INSPECT AND REMOVE GREASE FROM SLIP RINGS, BRUSHES AND OTHER INTERNAL PARTS OF THE GENERATOR.

4.15 BEARING REMOVAL

4.15.1 Remove the endbell to expose bearing. Use a puller to remove the bearing from the shaft. Protect the shaft end with a cap. Make certain puller applies pressure only against the bearing inner ring. If puller will not hook bearing inner ring, fabricate a split bushing and install it between the bearing and the puller hooks.

4.16 BEARING INSTALLATION

4.16.1 Heat the bearing to 250°F. in a clean temperature controlled circulating air oven Start the heated bearing onto the shaft. Then use a fiber or soft metal sleeve to tap bearing into place. Make certain that pressure is applied only to the bearing inner ring. Final position of bearing should be with inner ring resting against bearing shoulder on shaft. Assemble the generator after the bearing has cooled.

4.17 TROUBLESHOOTING

4.17.1 Troubleshooting is process of recognizing malfunctions of the system, intelligently analyzing the system malfunction, and making the necessary corrections to place the unit back into proper operation.

4.17.2 The systems operator is urged to be alert at all times for any signs of malfunctions. Any minor malfunctions should be corrected immediately to prevent serious malfunctions and down time. The troubleshooting chart lists symptoms of malfunctions which could possibly occur as well as the possible cause and remedy.

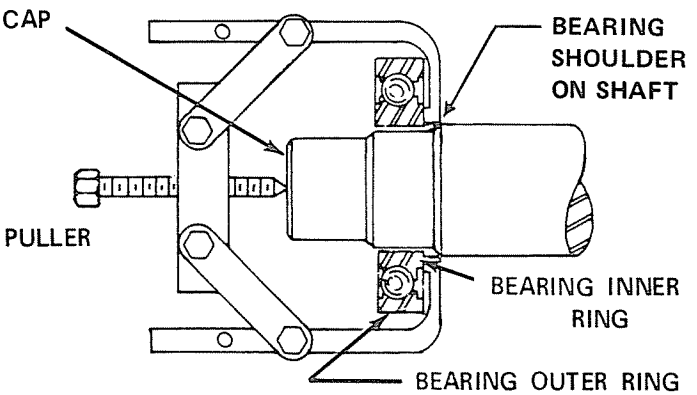

FIGURE 4-3 REMOVING BEARING FROM GENERATOR SHAFT.

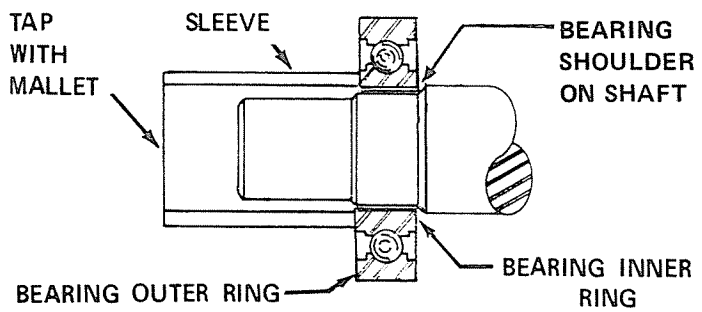

FIGURE 4-4 INSTALLING BEARING ON GENERATOR SHAFT.

Katolight Service - Master Repair Manual - Page 519

TABLE 4-2
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSES	REMEDY
No Voltage	Poor brush connection (either sliprings commutator, or brushes).	Clean and adjust or replace brushes. Clean, sand, or turn sliprings. Check that brush holders and brush wires are connected properly.
	Excitation (DC) lead open shorted or grounded to frame.	Check with continuity lamp or ohmmeter. Replace defective leads.
	Loss of residual magnetism.	Flash field.
	Short circuit in line or load.	Check for short in load by removing motors or appliances from the line. If short persists, the trouble is on the line. If line is clear, add motors or appliances one at a time until trouble is found.
	Field coils shorted or open.	Check for open circuit and for short circuit. Replace rotor if defective.
	Shorted or grounded sliprings.	Disconnect lead wires and check slipring insulation with a megger. Repair or replace slipring assembly if defective.
	Shorted commutator or shorted or open exciter armature windings	Repair commutator or replace exciter armature assembly.
Low Voltage	Excessive Load	Reduce load to rated value. See generator nameplate for rating
	Improper adjustment of voltage adjust rheostat	Adjust rheostat.
	Underspeed.	Correct speed of engine or motor driving generator.
	Insufficient excitation due to improper adjustment of voltage adjust rheostat	Increase field excitation by adjusting voltage. adjust rheostat
	Line loss	Increase size of line wire.
	High resistance connections (connections will be warm or hot).	Check connections. Replace or tighten defective connections
	Brushes dirty or not properly seated.	Clean or replace brushes.
	Sliprings or commutator dirty or in need of repair.	Clean or repair as necessary.
	Low power factor (AC only).	Reduce inductive (motor) load. Some AC motors draw approximately the same current regardless of load.

SYMPTOM	POSSIBLE CAUSES	REMEDY
Low Voltage (continued)	Weak field due to operating in warm temperature.	Improve the ventilation if generator is housed indoors. Field current can be increased providing the generator temperature does not exceed temperature rating stamped on the nameplate.
	Malfunction of voltage regulator when used	Repair or replace voltage regulator.
Fluctuating Voltage	Irregular speed of prime mover.	Check and adjust governing device.
	Poor brush contact.	Clean and adjust or replace brushes. Check brush tension spring pressure, 3 lbs. per square inch of brush surface nominal (2½ to 4 lbs/sq. inch generally satisfactory).
	Loose terminal or load connections.	Check connection. Tighten or replace defective connectors.
	Generator overloaded.	Reduce load to rated value. See generator nameplate for rating.
	Sliprings or commutator out of round or pitted	Turn sliprings or commutator on a lathe concentric with center of generator shaft
	DC excitation voltage fluctuating	Trace DC excitation through brushes, commutator, sliprings, and field coils and make repairs as necessary. Repair or replace defective parts.
	Shorted exciter field coil	Test for short circuit. Replace defective coil.
High Voltage	Improperly adjusted voltage adjust rheostat	Adjust rheostat.
	Overspeed	Correct speed of prime mover.
	Operating in sub-zero temperatures.	Increase field resistance.
	Defective voltage regulator	Repair or replace voltage regulator.
Brush Sparking	Sliprings and/or commutator surface not concentric to shaft, surface pitted or rough, slipring insulation defective. or high mica bars on commutator	Repair sliprings and/or commutator according to maintenance instructions.
	Loose brush holder.	Re-align and tighten.
	Lack of brush pressure	Adjust or replace brush tension spring. 3 lbs./sq. in. per inch of brush surface nominal (2½ to 4 lbs./sq. inch).
	Improper grade of brushes.	Replace with correct grade of brushes.
	Brushes not in commutating plane	Set to electrically neutral position.

SYMPTOM	POSSIBLE CAUSES	REMEDY
Brush Sparking (continued)	Dirty sliprings.	Sand lightly with 00 sandpaper.
	Open or shorted exciter armature	Check with growler. Repair or replace armature if defective.
	Generator overloaded.	Check ammeter readings and compare with nameplate rating.
Overheating	Generator overloaded.	Reduce load. Check ammeter readings and compare with nameplate rating.
	Clogged ventilating passages.	Clean air passages.
	High room temperature.	Improve ventilation.
	Insufficient circulation.	Provide cross-ventilation
	Operating with excessive voltage.	Check voltage drop in distribution lines and connections.
	Low power factor (AC only).	Reduce inductive load (motor), or install power factor improvement capacitors.
	Unbalanced load on 4 wire, 3 phase generators.	The load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Motors operating off generator not designed for generator frequency and voltage.	Motors operating from generator must be of the same frequency and voltage as stamped on the generator nameplate.
	Excessive brush pressure.	Reduce spring pressure. 3 lbs./sq. inch of brush surface nominal (2½ to 4 lbs./sq. inch).
	Bent shaft.	Straighten or replace.
	Defective bearing.	Replace bearing.
Vibration	Improper mounting, or misalignment of coupling or drive pulley.	Align motor and generator. Refer to Section 2.
	Incorrect mounting of generator to engine.	Re-install correctly. Refer to installation instructions contained in Section 2.
	Transfer of vibration to generator set from another source.	Isolate generator set by installing vibration dampeners. Refer to Installation Instructions. Section 2.
	Defective bearing.	Replace bearing. Refer to Section 4 paragraphs 4.15 & 4.16.
	Rotor out of balance following repair or replacement of generator rotor.	Balance rotor assembly with cooling fan installed.
	Defective rotor windings due to excessive overspeed.	Replace or repair rotor. Correct cause of overspeed (defective engine governor and/or engine overspeed shutdown devices).
	Loose or broken fan	Tighten or replace if broken.
	Bent shaft due to excessive load.	Straighten shaft or replace rotor.

4.18 DISASSEMBLY OF SINGLE BEARING GENERATOR

4.18.1 The following general instructions describe disassembly procedures for typical KATO single bearing generators and direct connected brush type DC exciters. Assemble the generator by reversing the order of the steps taken to disassemble the unit.

4.18.2 Disassemble generators of the type described above as shown in figure 4-5 as follows:

a. Remove outlet box cover and disconnect generator load lines, exciter field leads, and generator field leads.

b. Remove the generator from the engine by reversing assembly procedures. See Section 2, Installation.

c. Remove exciter cover (1). Make sure brushes (11) and (22) are raised in holders before generator is removed from the engine.

d. Remove generator base mounting bolts.

e. Using slings attached to the generator lifting eyes remove generator from base.

f. Disconnect exciter shunt field coil leads and generator field leads. Remove any clips securing field leads to exciter or generator frame.

g. Remove exciter armature retaining bolt and washer (2).

h. Remove exciter armature (3) and if used, aligning key (39).

i. Remove commutator endbell bolts (17). Tap to loosen endbell (16).

j. Check for shims in bearing well. Make certain shims, when incorporated, are reinstalled when generator is assembled.

k. Remove rotor from drive end of generator.

l. Remove bearings as described in paragraph 4.15.

m. Unless damaged, do not remove brush ring assembly (14).

4.19 DISASSEMBLY OF TWO BEARING GENERATOR

4.19.1 The following general instructions describe disassembly procedures for typical KATO two bearing revolving field generators with direct connected brush type DC exciters. Assemble the generator by reversing the order of the steps taken to disassemble the unit.

4.19.2 Disassemble generator of the type described above and as shown in figure 4-6 as follows:

a. Remove outlet box cover and disconnect generator load lines, exciter field leads and generator field leads.

b. Remove the generator from the prime mover by reversing assembly procedures. See Section 2, Installation. Remove coupling or drive sheaves in accordance with the instructions supplied by the manufacturer of the coupling.

c. Remove exciter cover (1). Make sure brushes (11) and (22) are raised in holders before generator is disassembled.

d. Remove generator base mounting bolts.

e. Using slings attached to the generator lifting eyes remove generator from base.

f. Disconnect exciter shunt field coil leads and generator field leads. Remove any clips securing field leads to exciter or generator frame.

g. Remove exciter armature retaining bolt and washer (2).

h. Remove exciter armature (3),and when used, aligning key (38).

i. Remove commutator endbell bolts (17). REmove endbell (16).

j. Remove drive endbell bolts (36). Remove endbell (32).

k. Check for shims in bearing wells. Make certain shims, when incorporated, are reinstalled when generator is assembled.

l. Remove rotor from drive end of generator.

m. Remove bearings (15) and (35) as described in paragraph 4.15.

n. Unless damaged, do not remove brush ring assembly (14).

4.20 ORDERING RENEWAL PARTS

4.20.1 If a part should require replacement, order by part name and part number. Give the model, type and serial number of the generator. Replacement parts should always be of the same size and rating as the original equipment. Do not attempt to substitute similar parts. For fastest service direct parts order to:

Kato Engineering Company Parts Department,

WARRANTY

Kato Engineering Company warrants that the apparatus manufactured by us will deliver its rated output, providing such apparatus is properly installed, properly cared for, and properly operated under normal envi ronmental conditions.

Standard products manufactured by Kato Engineering Company are warranted to be free from defects in workmanship and material for a period of one year from date of shipment, and any products which are defective in workmanship or material will be repaired or replaced at the option of Kato Engineering Company. Final determination as to whether a product is actually defective rests with Kato Engineering Company. The obligation of Kato Engineering Company hereunder shall be limited solely to repair and replacement at its factory, of products that fall within the foregoing limitations, and shall be conditioned upon receipt by Kato Engineering Company of written notice within the warranty period of any alleged defects or deficiency. No products shall be returned to Kato Engineering Company without its prior consent. In no case can Kato Engineering Company accept shipping charges incurred either through return of defective items to its factory or return of repaired or replacement item to the user. Kato Engineering Company cannot assume responsibility or accept invoices for unauthorized repairs to its components, even though defective. In the case of components, parts, or units purchased by Kato Engineering Company, the obligation of Kato Engineering Company shall not exceed the settlement that it is able to obtain from the supplier thereof.

The life of the products of Kato Engineering Company depends to a large extent upon type of usage therof, and Kato Engineering Company makes no warranty as to period of service nor as to fitness of its product for specific applications by the Buyer unless Kato Engineering Company specifically agrees to otherwise in writing after the proposed usage has been made known to it. In no event will Kato Engineering Company be liable for consequential or incidental damages or for any expense incurred by Buyer due to use or sale of products sold by Kato Engineering Company.

The foregoing warranty is exclusive and in lieu of all other warranties expressed or implied, including but not limited to any warranty of merchantability or of fitness for a particular purpose.

This Warranty does not apply to experimental or developmental products.

SECTION 1
INTRODUCTION AND DESCRIPTION

1.1 INTRODUCTION

This manual contains instructions for installing, operating and maintaining Kato Brushless Revolving Field Generators.

Electrical connection drawings, dimensional drawings and part listings for the specific model, type and serial number of generator are usually contained as supplementary information in a separate excerpt of the generator manual. These drawings are the official source of information for making electrical connections or ordering replacement parts.

1.2 GENERAL DESCRIPTION

1.2.1 The Synchronous Alternating Current Generators described in this manual are of the brushless revolving field type of single and two bearing construction. Single bearing generators are designed for direct coupling to a stationary prime mover and two bearing generators are designed for gear, belt or flexible coupling to a stationary prime mover. The generators are manufactured in many sizes and ratings with various optional features such as enclosures, terminal boxes, bearing types, and controls. Generator excitation current is supplied from a direct connected brushless rotating DC exciter.

1.2.2 The generators may be supplied with various controls designed to provide the user's exact power needs. Controls may be contained in separate wall mounted cubicles, in free standing control cubicles, or in a control box mounted to the generator frame depending upon the number and size of the controls required or the customer's specifications.

1.2.3 Generators may be supplied with permanent magnet generators (PMG) to provide power to the regulator under short circuit conditions, or field flashing (in case generator or brushless exciter loses residual magnetism) and to reduce electromagnetic interference.

1.2.4 Generators are supplied with a side mounted terminal box which is designed to accommodate the connections to the load. Specially built oversized box can also accommodate various controls and protection devices such as the voltage regulator, surge suppressors, and current transformers. Auxiliary boxes are provided to accommodate accessory connections to RTD's, space heaters, bearing vibration sensors, exciter and PMG leads.

1.3 CONSTRUCTION

The basic generator includes frame and stator, rotor, enclosures and brushless exciters with optional permanent magnet generator mounted on the shaft to provide power to the voltage regulator.

1.3.1 The generator frame is fabricated of heavy steel members welded to the endbell or bearing bracket pilot rings. The feet are welded to the frame to simplify installation and alignment with the primer mover. Eye bolts are fastened to the frame to enable lifting of the generator with an overhead hoist. Steel wrapper cover encloses the frame assembly.

1.3.2 The generator stator core is built of laminated electrical grade steel. Laminations are secured under pressure and clamped to steel endrings. Windings are inserted into the stator slots and the entire assembly is vacuum pressure impregnated with 100 percent epoxy resin (see Figure 1-1). Stator leads terminate in standard connection lug or strap copper terminals for ease of connection to the load (see Figure 1-2).

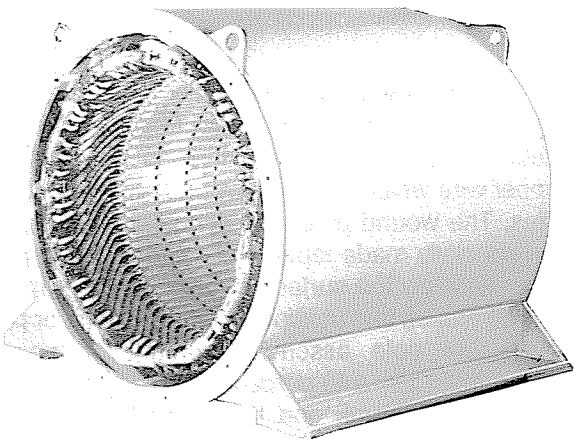

Figure 1-1
Stator of Kato Revolving Field Synchronous Alternating Current Generator

1.3.3 The generator rotor consists of the shaft, spider, fans, field poles and windings (see Figure 1-3).

1.3.3.1 The shaft is machined from high strength steel stock or forging. Mechanical center line is scribed on the drive end for units with floating bearings for proper alignment. On single bearings with forged flange holes are drilled to mate with the

engine flywheel and crankshaft.

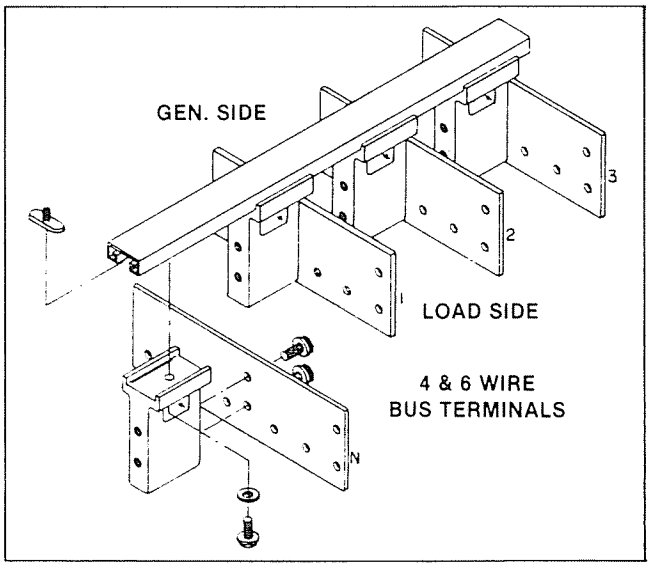

Figure 1-2
Lead Terminals Located in Outlet Box

1.3.3.2 The spider is laminated. On four pole, and small six and eight pole rotors, the spider is an integral part of the rotor pole. On other six pole and higher number of poles the spider is laminated with individual dovetails punched to anchor the field poles.

1.3.3.3 The poles are individually punched of high strength laminations which are held together with rivets or bolts. The field windings use insulated copper wire which are layer wound on the laminated poles. The wound poles are anchored to the spider with specially made tapered keys. Damper bars are inserted below the surface of the pole face and are welded/brazed to a continuous shorting ring or plate. The entire pole assembly is vacuum pressure impregnated with 100 percent epoxy resin. The rotor assembly is shrunk and keyed on the shaft. The rotor is dynamically balanced to specific limits to assure compliance to NEMA vibration limits and long bearing life. A single blower is dynamically balanced and mounted on the shaft at the drive end.

1.3.4 Brushless Exciter

The brushless exciter is an inverted synchronous AC generator with the field winding stationary and three phase armature windings rotating with the generator rotor. The AC output is rectified through a full wave semiconductor bridge (see Figures 1-4 and 1-5).

1.3.4.1 The exciter armature is built of laminations and riveted under pressure. Three phase windings are inserted in the slots and the entire assembly is vacuum pressure impregnated with 100 percent epoxy resin. The exciter armature is pressed on a tubing and keyed in position.

1.3.4.2 A three phase full wave rectifier made of three forward and three reverse diodes are mounted on two separate rings which act as negative and positive polarity heat sinks. The rectifier assembly is keyed on the same tubing as the exciter armature. Both exciter armature and rectifier assembly is dynamically balanced. The sleeve tubing is pressed and keyed on the main rotor shaft.

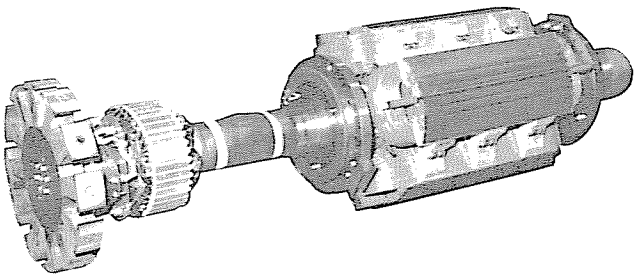

Figure 1-3
Generator Rotor with Exciter Armature and Rotating Rectifier Assembly Installed

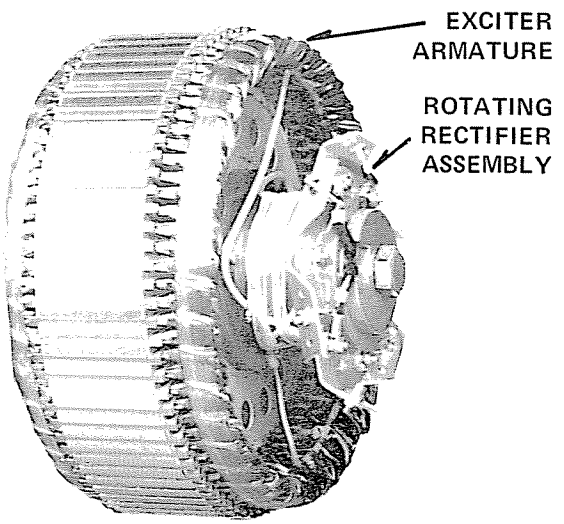

Figure 1-4
Exciter Armature and Rotating Rectifier Assembly

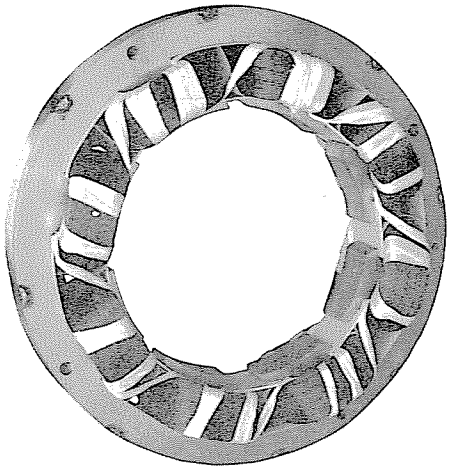

Figure 1-5
Exciter Stator and Windings

1.3.4.3 The exciter stator is built of laminations stacked under pressure and welded. Field windings are inserted and the entire assembly is vacuum pressure impregnated with 100 percent epoxy resin. The stator is mounted on the bearing bracket (endbell).

1.3.5 Permanent Magnet Generator (Optional)

The permanent magnet generator (PMG) provides power to the voltage regulator under all operating conditions regardless of the main generator output conditions. The PMG is a single phase AC generator with rotating permanent magnets providing excitation. For detailed description and operating instructions refer to Publication 350-01003-00 "Kato Pilot Exciters." The block diagram, Figure 1-8, illustrates the operation of the brushless excitation system.

1.3.6 Enclosures

Steel wrappers enclose the generator frame. A removable sheet metal covers the entire exciter assembly. Ambient air is drawn into the machine through openings at the exciter end and exhausted through screened openings enclosing the blower assembly. Enclosures can be open dripproof, splash proof, and filtered construction.

1.3.7 Bearings

Heavy duty "greased for life" double shield bearings are used on small generators less than 75 Kw. On large machines bearings are of "regreasable" design. The bearing housings are provided with grease fill and drain ports for easy lubrication (see Figures 1-6 and 1-7).

Roller bearings and sleeve bearings are also incorporated on special designs and applications. A supplementary instruction manual is included for these bearings.

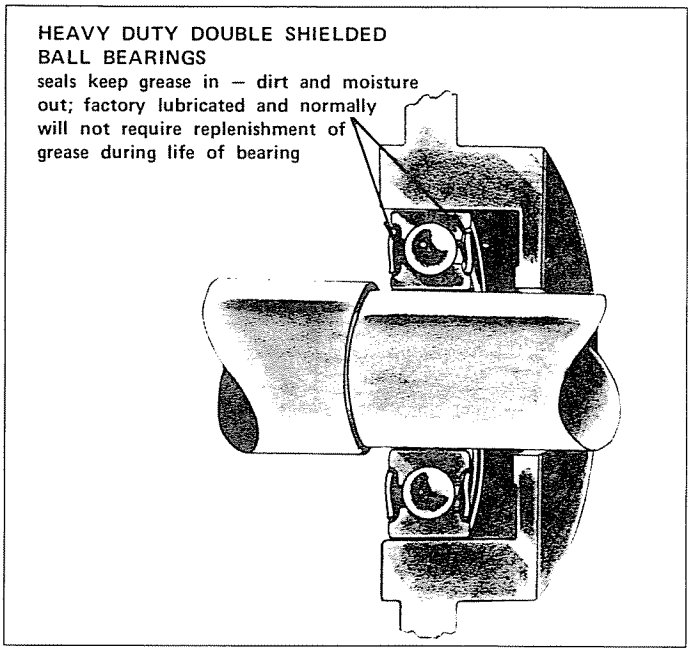

Figure 1-6
Typical "Shielded" Bearing and Bearing Housing Construction

Typical "Regreasable" Bearing and Bearing Housing Construction

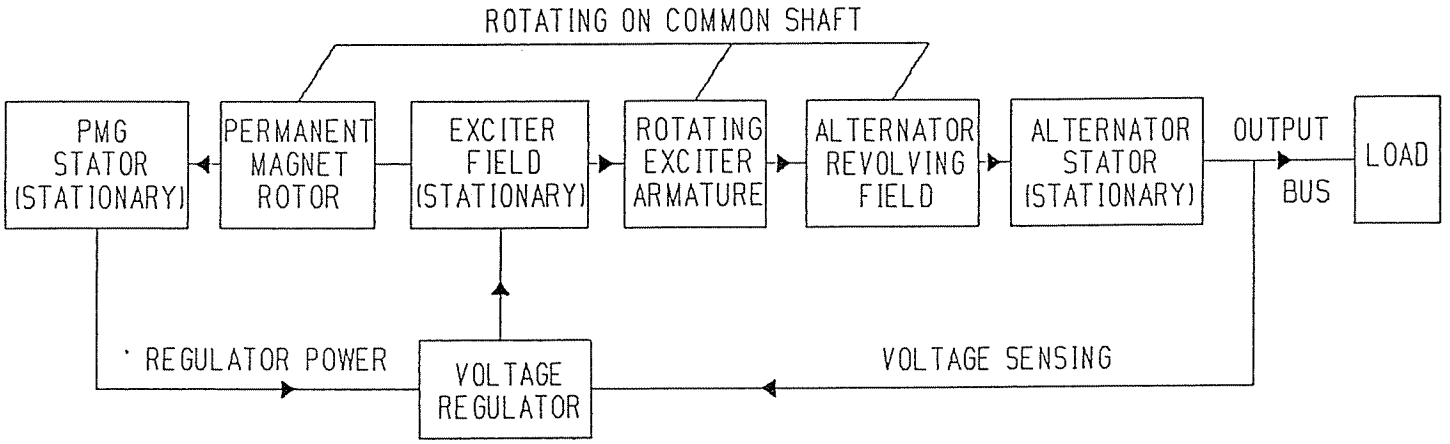

Figure 1-8
Block Diagram, Typical Brushless Generator - Voltage Regulator System

SECTION 2
INSTALLATION

2.1 RECEIVING INSPECTION

Two-bearing generators are shipped completely assembled. Single bearing units are shipped with brushless exciter armature and rectifier assembly removed from the shaft.

NOTE: Prior to accepting shipment from the transportation company, examine crating for any damage which might have occurred during transit. Report any evidence of crating damage to transportation company claims office and Kato Engineering.

If the generator is received during cold weather, allow the crated unit to reach room temperature before removing the protective packing material. This will reduce the condensation of moisture on cold surfaces and prevent early failures due to wet windings and insulating materials.

2.2 UNPACKING AND STORAGE

2.2.1 Moving Generator

Unpack the equipment with care to avoid scratching painted surfaces. Move the unit to the mounting location either by attaching an overhead hoist to the eye bolts installed on the generator frame or by lifting the generator form underneath the skid with a forklift. Hoist and hoist cables should have a rating of not less than 1-1/2 times the weight of the generator. When moving unit with a forklift, make certain it is completely onto and balanced on the forklift tines.

WARNING

Apply lifting force to structural points specifically provided for that purpose. DO NOT USE enclosure lifting holes to lift the whole unit. Use lifting means adequate for the weight. Failure to observe these instructions can result in injuries to personnel and damage to the generator.

2.2.2 Rotor Support

All single bearing generators are shipped from factory with rotor shipping support blocking bolted across the drive discs and adaptor. Before transporting any generator, the main rotor must be supported by the adaptor using an appropriate fixture.

CAUTION

Do not attempt to transport any single bearing generator without proper rotor support. Failure to observe this precaution can result in extensive equipment damage. Make certain exciter rotor is removed while handling generator.

2.2.3 Storage

2.2.3.1. Short Term Storage

If the generator is not to be installed in its operating location immediately, it is recommended that it be stored in a clean dry area not affected by rapid changes in temperature and humidity. If space heaters are supplied, they should be energized to keep condensation from the windings. All accessory equipment supplied with the unit should be stored with the generator, and the combined unit covered with durable cover for protection against dust, dirt, moisture and other airborne contaminants.

2.2.3.2. Long Term Storage

Units which are to be in storage for a period longer than six months should be prepared for storage as follows:

a. Install desiccant bags in the exciter cover and inside the fan screen.
b. Vacuum seal the unit in a covering of plastic or other material designed for that purpose.
c. Adequately tag the generator to insure that preservative greases and desiccant bags are removed before the unit is placed in operation.

2.2.4 Bearing Inspection

Grease used in ball bearing generators is subject to time deterioration. If the generator is stored for one year or longer, it is recommended that new ball bearings be installed and greased to the proper level before putting into operation. If inspection indicates that bearings are free of rust or corrosion,, and no noise or excessive vibration appear on start-up, replacement is not necessary.

2.3 LOCATION

The location of the generator must comply with all local and special industrial regulations. Attempt to locate the generator in clean, dry, well ventilated area, easily accessible for inspection and maintenance. Air inlet and discharge openings must not be obstructed to the flow of

accessible for inspection and maintenance. Air inlet and discharge openings must not be obstructed to the flow of coolant air. If the location is subject to harsh environmental conditions, the generator can be field modified to incorporate dust filters and space heaters. In addition it is recommended that a more rigid periodic maintenance be established.

2.4 ASSEMBLY TO PRIME MOVER

2.4.1 Assembling Single Bearing Generator to Prime Mover

See Figure 2-1 for typical method of coupling single bearing generator to prime mover. The generator and prime mover should be mounted on a rigid level base. The following steps describe the assembly work:

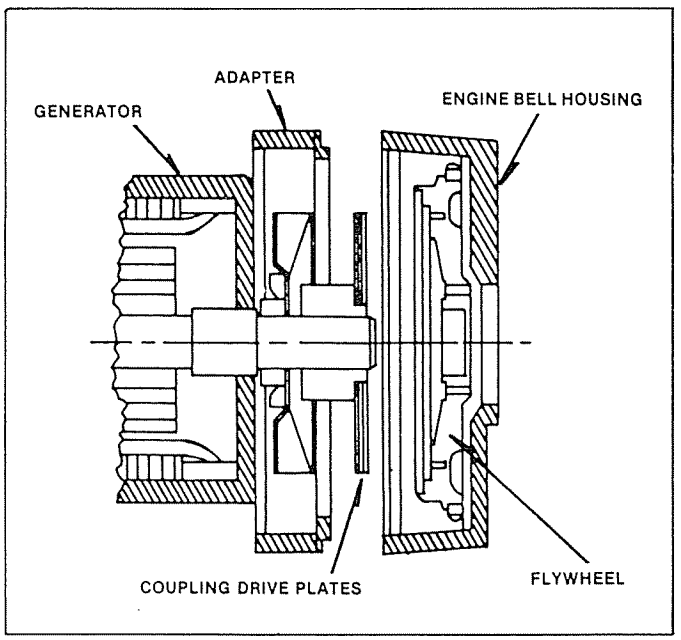

Figure 2-1
Typical Single Bearing Generator-Engine Coupling

2.4.1.1 Before assembling generator to prime mover, remove exciter cover and adaptor cover or screen. Remove blocking holding the drive discs to the adaptor.

NOTE: If exciter armature and rotating rectifier assembly was not installed (shipped as loose equipment), do not install it until the generator has been assembled to the prime mover.

2.4.1.2 Before assembling generator to the prime mover, check to make certain generator bearing and clearance is sufficient. GENERATOR BEARING END CLEARANCE SHOULD NOT BE LESS THAN TOTAL ENGINE CRANKSHAFT AXIAL MOVEMENT PLUS 1/16 INCH.

NOTE: Generator shipped from factory with approximately 1/8 inch minimum bearing end clearance.

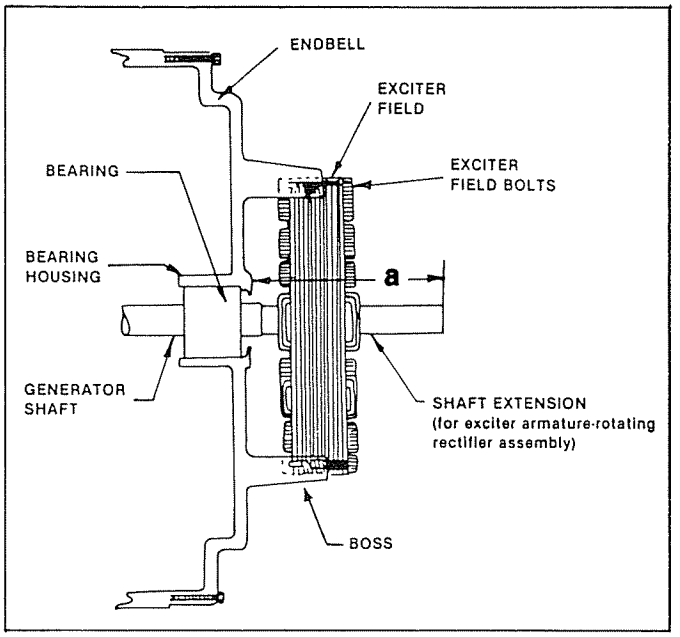

Figure 2-2
Extension of Generator Rotor Shaft for Mounting of Exciter Rotor Assembly (Outboard Exciter Generators)

Before attempting to mount the generator to the engine, measure the distance from the end of the exciter shaft extension to the bearing housing on the endbell as shown on Figure 2-2. This dimension is recorded on Section P-1 of the Assembly Manual. If the dimensions do not match, move the rotor axially relative to the stator until dimensions are identical.

2.4.1.3 Check the run-out of the prime mover flywheel and flywheel housing (bell housing) with a dial indicator as shown in Figures 2-3 and 2-4. TOTAL INDICATOR READING SHOULD NOT EXCEED .003 INCH PER EACH FOOT OF DIAMETER OF FLYWHEEL AND BELL HOUSING, SEE TABLE 2-1. If reading exceeds the allowable limit, excessive vibration could result. Contact the prime mover manufacturer for recommendations.

TABLE 2-1
Allowable Flywheel & Drive Disc Recess Run-out

FLYWHEEL DRIVE DISC RECESS		
Pilot Diameter	Nominal Clutch Dia.	Allowable Runout (Total Indicator Reading)
6½	8.500	.002
7½	9.500	.002
8	10.375	.002
10	12.375	.003
11½	13.375	.003
14	18.375	.004
16	20.375	.005
18	22.500	.005
21	26.500	.006
24	28.875	.007

6	10.500	.002
5	12.375	.003
4	14.250	.003
33	16.125	.004
2	17.625	.004
1	20.125	.005
½	23.000	.005
0	25.500	.006
00	31.000	.007

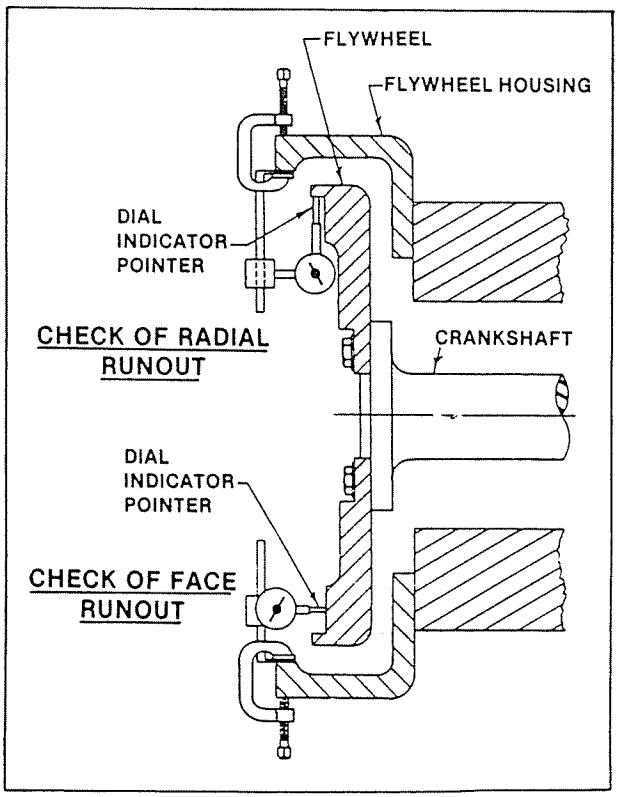

Figure 2-3
Checking Flywheel Run-out

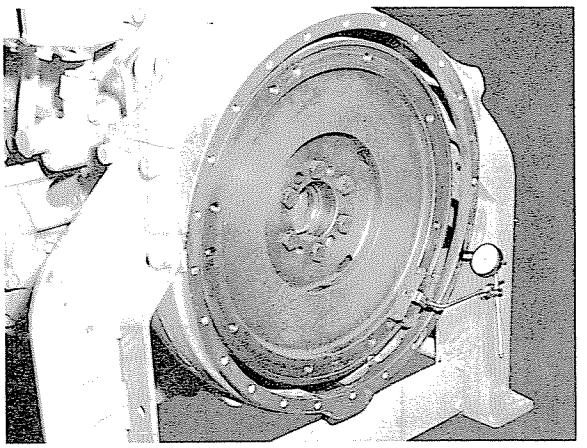

Figure 2-4
Checking Engine Flywheel Housing Run-out

2.4.1.4 Measure the axial distance from the surface on the generator adaptor that bolts to the prime mover flywheel housing to the outside surface on the drive disc coupling plates (Dimension "Y" Figure 2-5).

Also measure the axial distance from the machined surface on the prime mover flywheel housing to the bottom of the drive disc recess in the flywheel (Dimension "G" Figure 2-6). Contact factory if difference in dimensions "G" in Figure 2-6 and "Y" in Figure 2-5 exceed 1/32 inch. If "G" is more than "Y" install additional spacers between drive discs and generator drive hub. If "Y" is more than "G", remove spacers located between the drive discs and generator drive hub (see Figure 2-7).

2.4.1.5 Make certain drive discs "seat" in the drive disc recess of flywheel.

CAUTION

Never grind OD of drive discs or attempt to "drill out" holes in drive discs. If drive discs do not fit properly, order new discs or flywheel after carefully checking the dimensions of both parts.

2.4.1.6 Use lock-washers on all bolts used to secure the generator to engine and base. Use recommended torque values for each type of cap screws given in Table 2-2. If the bolts that secure the drive discs to the flywheel cannot be installed due to insufficient clearance between fan and drive disks, it may be necessary to loosen and move fan.

1 1/2	1748	3150

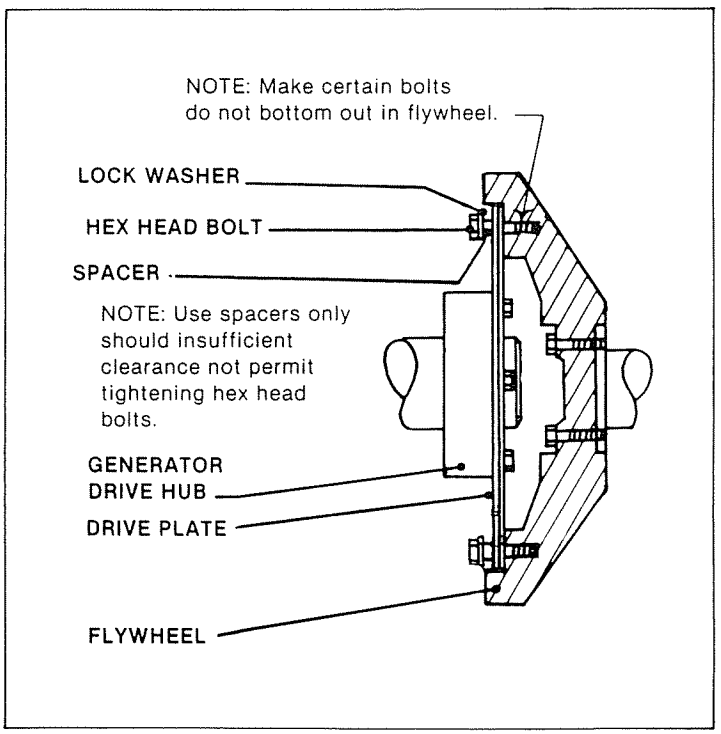

Figure 2-7
Typical Drive Disk to Flywheel Installation

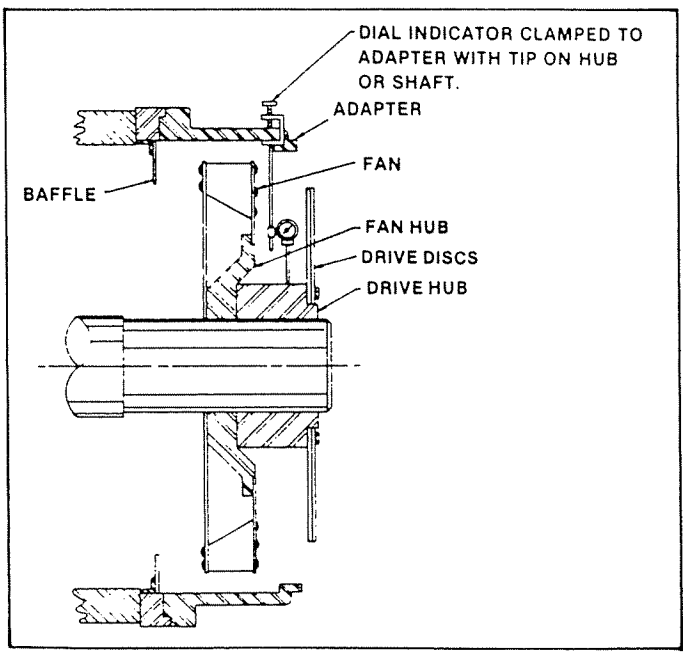

Figure 2-8
Checking Generator Shaft Run-out

CAUTION

If fan is moved, make certain that before generator set is placed in operation, fan is positioned with about 1/2 inch clearance between fan and baffle and all fan bolts are installed and tightened.

NOTE: Check to make ceratin bolts do not bottom out in flywheel. If bolts are too long or cannot be tightened with socket or box wrench, use 1/4 to 3/8 inch long spacers inserted on the bolts as shown in Figure 2-7 to increase the clearance between the bolt head and the flywheel.

2.4.1.7 Before installing the fan screen, check run-out of the generator shaft. Check run-out by placing the base of the dial indicator on the generator frame rib end positioning the indicator finger on the shaft as shown in Figure 2-8. Total shaft run-out should not exceed .003 inch. If this figure is exceeded, remove drive disc bolts and rotate generator relative to the engine flywheel. Reinstall bolts and check run-out again.

2.4.1.8 Make sure generator mounting pads contact the base evenly and with equal pressure. Use shims if necessary. Recheck shaft end to endbell distance (Dimension "a" in Figure 2-2).

2.4.1.9 Mount the brushless exciter armature and rotating rectifier assembly to the generator shaft. The exciter rotor unit is held in place on the shaft by a key in the shaft and a bolt and washer at the end of the shaft. Install key in the machined keyway on the generator shaft. Align exciter rotor unit with key and push the exciter rotor unit onto the shaft. Install washer and retaining bolt. Torque bolt with 1/2 inch shank diameter 60 ft-lbs, 3/4 inch shank diameter bolt 200 ft-lbs. See Figure 2-9 and 2-10.

DO NOT APPLY FORCE TO THE ROTATING ASSEMBLY OR EXCITER ARMATURE WINDING.

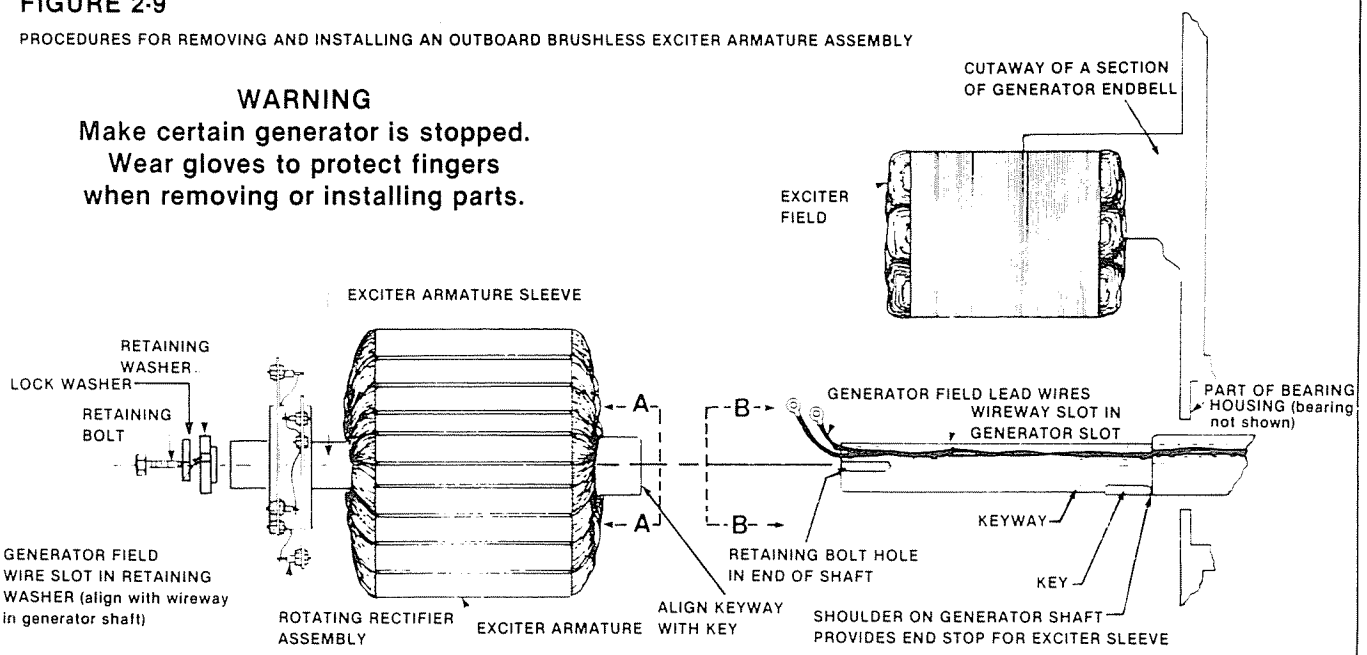
Inspect the clearance between stationary and rotating parts. Connect positive (+) and negative (-) leads from generator field onto positive (+) and negative (-) terminals located on the aluminum heat sinks of rotating rectifier assembly.

2.4.1.10 Turn engine several revolutions. Use a crank or barring device but do not pry on the fan. Visually inspect clearance between generator stationary and rotating parts. Listen for unusual noises such as produced by parts rubbing together.

FIGURE 2-9

PROCEDURES FOR REMOVING AND INSTALLING AN OUTBOARD BRUSHLESS EXCITER ARMATURE ASSEMBLY

WARNING
Make certain generator is stopped. Wear gloves to protect fingers when removing or installing parts.



REMOVAL

1. Remove exciter cover.
2. Remove retaining bolt and washer.
3. Disconnect (+) and (−) generator field wires at (+) and (−) terminals on rotating rectifier assembly heat sinks.
4. Slowly pull exciter armature rotating rectifier assembly, as a unit, off of the generator shaft. Make certain generator field wires are flat in wireway in generator shaft and are not accidently torn when exciter is pulled.

CAUTION: Do not pull on edges of heat sinks or on exciter armature windings.

NOTE: If exciter armature will not pull from generator shaft by hand force, refer to generator instruction manual for proper installation of mechanical pullers.

5. Remove key from keyway in generator shaft.

INSTALLATION

1. Clean inside of exciter sleeve and outside of generator shaft.
2. Place key in the keyway in generator shaft.
3. Lay generator field wires flat in wireway in generator shaft with wire ends protruding past the end of the generator shaft.
4. Position the exciter armature rotating rectifier assembly in line with generator shaft and turn assembly to position where keyway in the exciter sleeve is in line with the key in generator shaft.
5. Using hand force, push the exciter armature rotating rectifier assembly over the generator shaft.

NOTE: Final position is with end of exciter sleeve against shoulder on generator shaft. It may be necessary to tap lightly on end of exciter sleeve in order to move the assembly over the key. Use a fiber or rubber mallet.

6. Connect (+) and (−) generator field wires onto (+) and (−) terminals on heat sinks.
7. Install retaining washer and bolt. Make certain generator lead wires are through slot in washer.
8. Torque the retaining bolt. Recommended torque is 60 foot/pounds for ½ inch diameter bolt and 200 foot/pounds for ¾ inch diameter bolt.
9. Use a feeler gauge to measure air gap between exciter armature and exciter field.
10. If air gap is less than recommended minimum check the following: (1) check generator to engine alignment; (2) if unit has been in operation, check for excessive bearing wear; (3) if generator has been taken apart and reassembled, check endbell and exciter field for loose mounting bolts and misalignment.
11. Install exciter cover when air gap is satisfactory.

AUXILIARY VIEW A-A

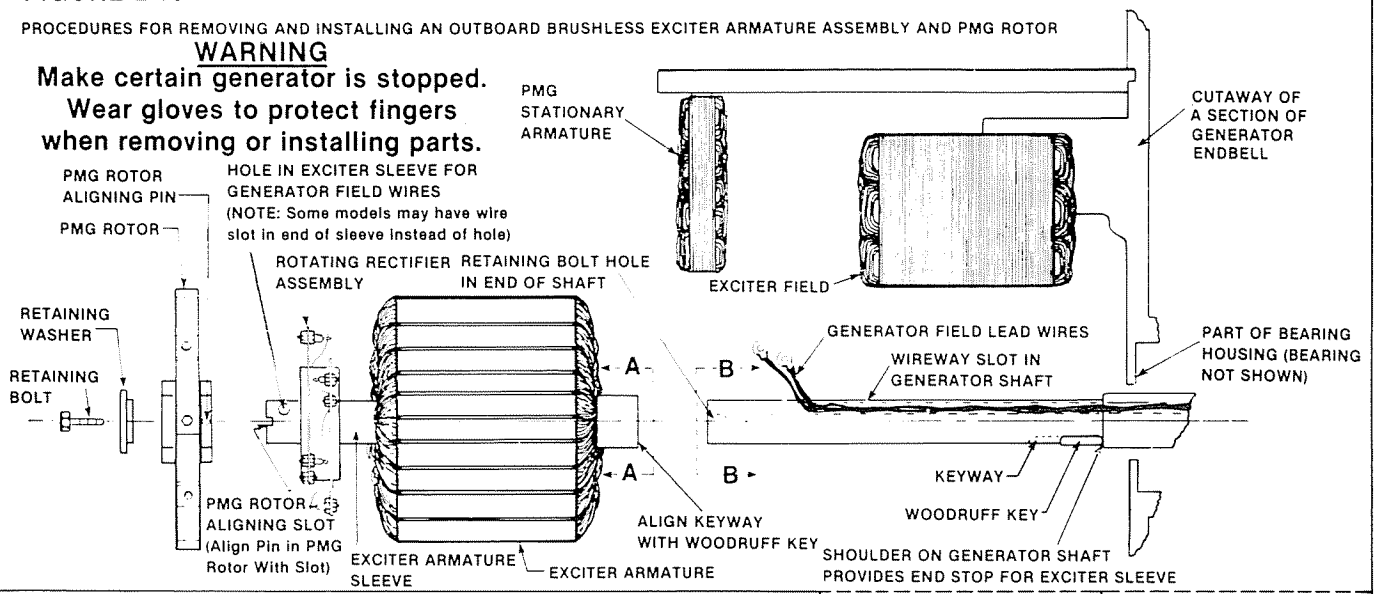
12 1/2	0.018
16 1/4	0.035

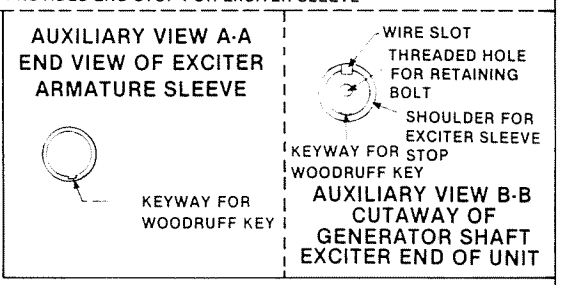
FIGURE 2-10

PROCEDURES FOR REMOVING AND INSTALLING AN OUTBOARD BRUSHLESS EXCITER ARMATURE ASSEMBLY AND PMG ROTOR

WARNING

Make certain generator is stopped. Wear gloves to protect fingers when removing or installing parts.





REMOVAL

1. Remove exciter cover.
2. Remove retaining bolt and washer.
3. Disconnect (+) and (−) generator field wires at (+) and (−) terminals on rotating rectifier assembly heat sinks.
4. Pull PMG rotor. The PMG rotor can be removed using hand force, however, the magnetic pull of the PMG rotor toward the exciter armature sleeve and the PMG armature must be overcome.
5. Slowly pull exciter armature rotating rectifier assembly, as a unit, off of the generator shaft. Feed generator field wires through wire hole in exciter sleeve while pulling exciter armature rotating rectifier assembly from the generator shaft.

CAUTION: Do not pull on edges of heat sinks or on exciter armature windings.

NOTE: If exciter armature will not pull from generator shaft by hand force, refer to generator instruction manual for proper installation of mechanical pullers.

6. Remove woodruff key from keyway in generator shaft.

INSTALLATION

1. Clean inside of exciter sleeve and outside of generator shaft.
2. Place woodruff key in the keyway in generator shaft.
3. Lay generator field wires flat in wireway in generator shaft.
4. Position the exciter armature rotating rectifier assembly in line with generator shaft and turn assembly to position where keyway in the exciter sleeves is in line with woodruff key in generator shaft.
5. Using hand force, push the exciter armature rotating rectifier assembly over the generator shaft. When it is part of the way onto the shaft, start the generator field wires through wire hole or slot in the exciter sleeve.
6. Push exciter armature rotating rectifier assembly the rest of the way onto the shaft while pulling lightly on ends of generator field wires in order to keep them straight in wireway in generator shaft.

NOTE: Final position is with end of exciter sleeve against shoulder on generator shaft. It may be necessary to tap lightly on end of exciter sleeve in order to move the assembly over the woodruff key. Use a fiber or rubber mallet.

7. Connect (+) and (−) generator field wires onto (+) and (−) terminals on heat sinks.
8. Place PMG rotor onto end of exciter sleeve.

CAUTION: Make certain PMG rotor pin is aligned with pin slot in end of exciter sleeve.

9. Install retaining washer and bolt.
10. Use feeler gauge to measure air gap between exciter armature and exciter field. Minimum air gap is 0.014 inch.
11. Use a feeler gauge to measure air gap between PMG rotor and PMG armature. Minimum air gap is 0.020 inch.
12. If air gap is less than recommended minimum, check the following: (1) check engine alignment; (2) if unit has been in operation, check for excessive bearing wear; (3) if generator has been taken apart and reassembled, check endbell and exciter field for loose mounting bolts and misalignment.
13. Install exciter cover when air gap is satisfactory.

2.4.2 Assembling Two Bearing Generator to Primer Mover

2.4.2.1 Install shims if necessary to properly level and align the generator to the primer mover.

2.4.2.2 Install coupling hubs on generator and drive shafts in accordance with the installation procedures specified by the coupling manufacturer. Check for angular and parallel alignment as shown in Figure 2-11 using dial indicator.

2.4.2.3 To check for parallel shaft (run-out) misalignment, bolt the indicator to one of the coupling halves and scribe the position of the dial button on the opposite coupling half. Rotate both shafts simultaneously, keeping the finger or button of the indicator at the reference mark on the coupling hub. Note the reading on the indicator dial at each one quarter revolution. A variation of readings at different positions will indicate how the machine should be adjusted to obtain maximum misalignment of .002 inch. Place or remove slotted shims from under engine or generator mounting pads until properly aligned.

2.4.2.4 To check to angular misalignment, fasten the dial indicator to one half of the coupling hub and a reference surface fastened to the other coupling half. Scribe the location of the dial button on the reference surface and take all readings with the indicators at this position. Rotate both shafts simultaneously, note the reading at each quarter revolution.

ANGULAR MISALIGNMENT OF THE SHAFTS MUST NOT EXCEED .001 INCH FOR EACH INCH OF RADIUS OF THE COUPLING HUB, TOTAL INDICATOR READING.

2.4.2.5 Tighten the mounting bolts and recheck alignment. If alignment is within the above tolerance, check coupling manufacturer's recommendation for lubrication and bolting information.

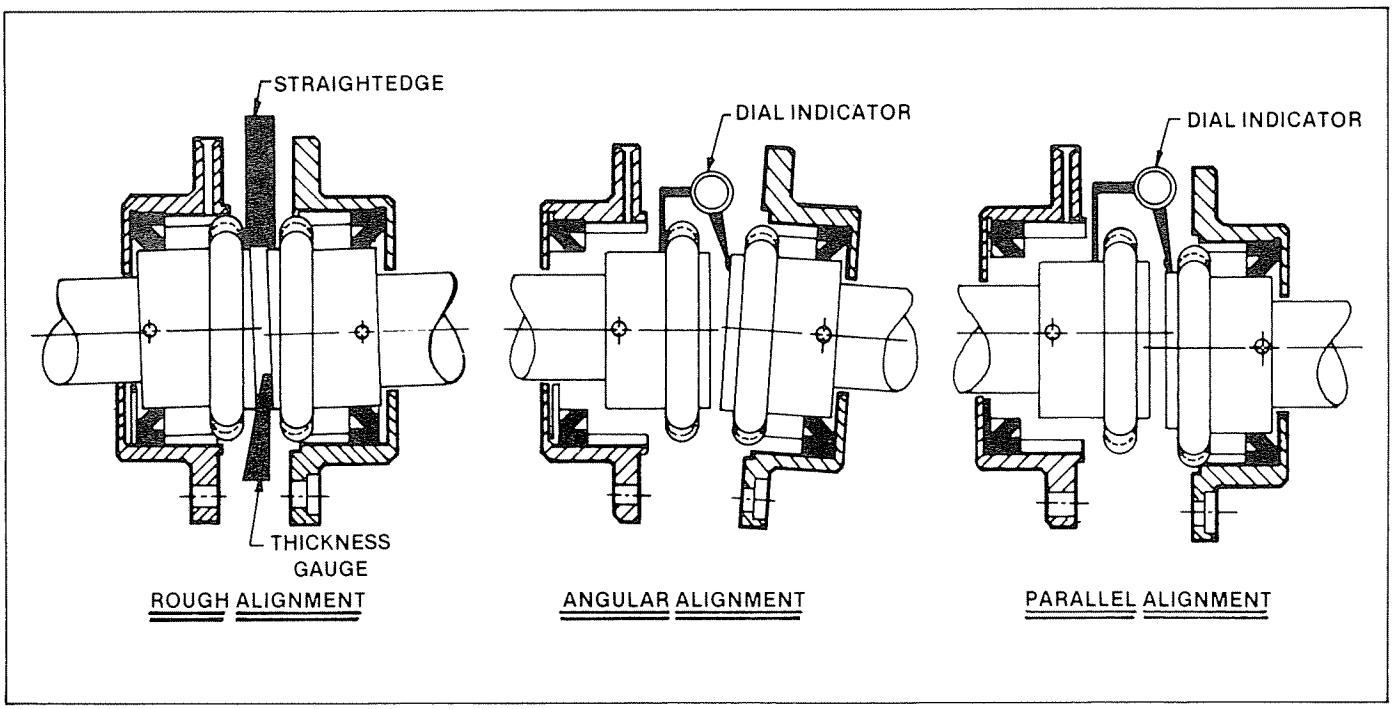


Figure 2-11
Testing Coupling Alignment

2.5 BELT DRIVES - GENERAL INFORMATION

Proper alignment and tightness of belt drives is essential. Improper alignment and belt tightness will increase belt wear as well as increase bearing loads and vibration. Select belt drive in accordance with belt manufacturer's specifications. Make certain generator and prime mover are rigidly mounted. In general, belt drives are not recommended when belt speed exceeds 5000 feet per minute.

2.6 V-BELT

2.6.1 Use only matched belt sets and avoid minimum pitch sheaves and belts. Follow the manufacturer's specifications or NEMA limits for sheave pitch.

2.6.2 Make certain the shaft axis of the prime mover and generator are paralleled. Belts must enter and leave sheaves with no side bending. Tighten just enough to prevent slippage at full load. Never grease or use belt dressing on belts.

2.7 FLAT BELT

Selection of belts and pulleys of ample width will reduce amount of tension required to prevent slippage at full load. Lower belt tension reduces bearing loads and belt wear.

2.8 GEAR BELTS (TIMING BELTS)

In general, installation of gear-belts will be the same as for flat belts. The following precautions should be taken when installing a gear-belt drive.

2.8.1 Gear-belts should be installed with snug fit, neither too tight not too loose. High initial tension is not necessary but when torque is unusually high a loose belt may "jump grooves." If the belt "jumps the grooves," the tension should be increased gradually until satisfactory operation is attained.

2.8.2 Be sure that shafts are parallel and pulleys are in alignment. On a long center drive, because of the tendency of the belt to run against one flange, it is sometimes advisable to offset the driven pulley to compensate.

2.8.3 On a long center drive it is imperative that belt sag is not enough to permit teeth on the slack side to engage the teeth at the tight side.

2.8.4 It is important that both prime mover and generator are mounted rigidly to prevent variation in belt tension.

2.8.5 Although belt tension requires little attention after initial installation, provision should be made for some center distance adjustment to ease in installing and removing belt. Do not force belt over flange of pulley.

2.9 GEAR AND FLEXIBLE COUPLINGS - GENERAL INFORMATION

When drives of these types are used instead of belt drives the prime mover and generator shafts must be carefully aligned and following alignment, the set must be firmly mounted to a rigid base to prevent misalignment of the unit shafts during operation. Excessive misalignment may be the cause of vibration, noisy operation, excessive coupling or gear wear or premature bearing failure.

2.10 GEAR DRIVE

2.10.1 Accurate alignment and rigid mounting are essential for satisfactory operation with gear drives. Pitch diameter and width should not be outside recommended NEMA limits and AGME Standards. Avoid coupling which will impose excessive thrust on bearings.

2.10.2 Check for backlash through at least one revolution of shaft. Backlash at tightest point should be in accordance with AGME Standards. Avoid engagement of teeth so deep that they will bind or deflect.

2.11 INSTALLATION AND ALIGNMENT OF FLEXIBLE COUPLED DRIVES

2.11.1 The procedures outlined are for aligning flexible coupled drives. Follow the tolerances specified by the coupling manufacturer when less than described in this manual.

2.11.2 Install coupling hubs on generator and drive shafts in accordance with the installation procedures supplied by the manufacturer of the coupling. Then check for angular misalignment by scribing a reference mark on the coupling hub at the button or finger of the indicator to mark its position on the hub. Rotate both shafts simultaneously, keeping the finger or button of the indicator at the reference marks on the coupling hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to Figure 2-11 for test setup.

ANGULAR MISALIGNMENT OF THE SHAFTS MUST NOT EXCEED .001 INCH FOR EACH INCH OF RADIUS OF THE COUPLING HUB, TOTAL INDICATOR READING.

2.11.3 If angular misalignment is excessive, loosen set mounting bolts and place slotted shims under mounting pads, as necessary, to correct alignment. Re-check alignment. Install or remove shims from under the mounting pads until aligned.

2.11.4 Check for parallel shaft (run-out) alignment by scribing a reference mark on the ground or machine diameter of the coupling hub at the finger or button of the indicator. Rotate both shafts simultaneously, keeping the button or finger of the indicator at the reference mark on the hub. Note the reading on the indicator dial at each one-quarter revolution. Refer to Figure 2-11 for test setup.

TOTAL RUN-OUT BETWEEN HUBS SHOULD NOT EXCEED .002 OF AN INCH.

2.11.5 When run-out between hubs is excessive, install or remove shims from under each of the prime mover or generator mounting pads; then re-check alignment. Add or remove shims until shafts are parallel. Tighten the set mounting bolts following angular and run-out alignment. Check base mounting bolts for tightness. Re-check alignment before installing coupling.

2.12 FLYWHEEL AND TWIN DISC CLUTCH OR OTHER FLEXIBLE COUPLING

A flywheel and twin disc clutch coupling provides a satisfactory coupling for motor-generator sets operating with shaft speeds not in excess of 3760 RPM. The coupling should be parallel between the spider and the rings. Align within .03 inch total indicator reading between spider and ring by installing or removing shims, as necessary, from under motor or generator mounting pads (see Figure 2-12).

2.13 VIBRATION

After alignment of prime mover to generator has been completed, run unit at no load and check for excessive vibration. If vibration is excessive loosen one mounting bolt slightly and if vibration decreases, add shims until tightening of bolt reduces or eliminates vibration. Repeat in turn for all mounting bolts.

NOTE

Vibration of direct coupled engine driven generators may be due to improper installation of generator to engine. If excessive vibration of engine driven generator is note, review the installation procedure.

2.14 DOWELING

Doweling generator sets will prevent movement of the units during operation should the mounting bolts loosen slightly. Install dowels as follows.

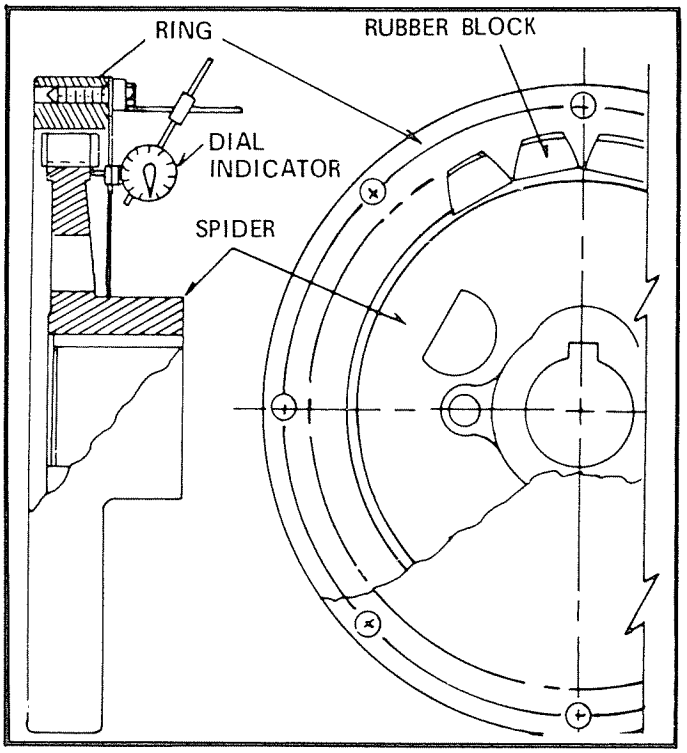

Figure 2-12
Checking Alignment of Twin Disc Coupling

2.14.1 Check the alignment after the generator set has been in operation about 40 hours. Correct alignment if not satisfactory (refer to preceding paragraphs).

2.14.2 Through opposite generator pads drill holes through and into the base. Holes should have a diameter slightly smaller than the dowel pin.

2.14.3 Ream the holes to the proper diameter for the pints, clean out chips and then install pins.

2.14.4 Repeat procedure for doweling of prime mover according to instructions supplied by the primer mover manufacturer.

2.15 ELECTRICAL MEASUREMENTS AND CONNECTIONS

In the event the generator was subjected to rapid changes in temperature or freezing or wet climate during shipment or storage, it is recommended that the insulation resistance of each winding be measure.

CAUTION

These tests should be conducted before any power and control connections are made.

2.15.1 Exciter Field

2.15.1.1 Disconnect the exciter leads from the terminals in the terminal box.

2.15.1.2 Connect exciter leads to one clamp of 500 volt megger and connect the other clamp to the generator frame.

2.15.1.3 Apply 500 volts from the megger and measure the resistance reading after one minute. The minimum reading should be 1.0 megohm. If not, refer to dry out procedures.

2.15.1.4 Short the exciter field leads to the generator frame for several minutes after the megger has been disconnected. This will allow the voltage build up to be properly discharged.

2.15.2 Exciter Armature

2.15.2.1 Disconnect the exciter armature leads from the rotating rectifiers. Disconnect the generator field leads from the positive and negative rectifier heat sinks.

2.15.2.2 Never apply megger to rotating rectifiers. Connect the leads of exciter armature to one clamp of a 500 volt megger and connect the other clamp to suitable connection on the shaft.

2.15.2.3 Record the megohm reading after one minute of applying 500 volts.

2.15.2.4 One minute reading must be a minimum of 1 megohm. If not, refer to dry out procedures.

2.15.2.5 Ground the exciter leads to the shaft after disconnecting the megger.

2.15.3 Generator Rotor Winding

2.15.3.1 Connect the positive and negative leads to one clamp of the 500 volt megger and connect the other clamp to the shaft.

2.15.3.2 Record the megohm reading after one minute of applying 500 volts.

2.15.3.3 One minute reading must be a minimum of 1 megohm. If not, refer to dry out procedures.

2.15.3.4 Ground the field leads to the shaft after disconnecting the megger.

2.15.4 Generator Stator

2.15.4.1 Disconnect power connections, if any, and all control apparatus from the generator terminals.

2.15.4.2 Measure insulation resistance of each phase separately with the two phases shorted to the frame.

2.15.4.3 Use a 500 volt megger connected between the lead of the phase to be measured and generator frame. The minimum one minute insulation resistance (corrected to 40 degrees centigrade) should not be less than that given by the following formula:

$$\text{Resistance in megohms} = \frac{\text{Rated generator voltage}}{1000} + 1$$

If less than above, refer to dry out procedure.

2.15.4.4 Ground the leads to the frame after the one minute megger test.

NOTE: The insulation resistance value increases with decreasing winding temperatures. All readings must be referenced to winding temperatures. Use Figure 2-13 for converting megger readings to other temperatures.

2.15.5 Drying Methods

If the insulation resistance readings are below the recommended minimum values specified previously, use one of dry out methods described below. The method selected should be based on the size and location of the unit, and available equipment with experienced personnel.

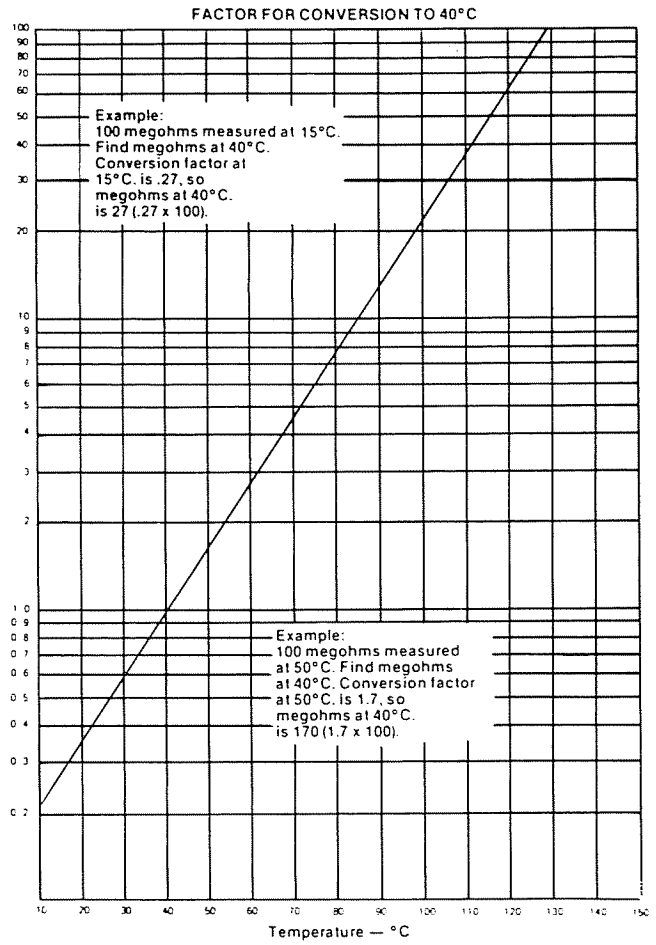

Figure 2-13
Chart for Converting Megger
Readings to 40 Degrees Centigrade

Remove voltage regulator and cover all inlet and discharge openings. Provide an opening at the top of the machine, preferably at the fan end, for moisture to evaporate. Monitor winding temperatures. DO NOT APPLY HEAT TOO RAPIDLY. Winding temperature should be raised gradually at a rate of 10 degrees centigrade per hour up to 93 degrees centigrade (200 degrees fahrenheit). Measure insulation resistance at one hour intervals. Typically the insulation resistance will slowly drop while the temperature is coming up, and then gradually increase and level off.

2.15.6 All electrical connections to the generator must be made in accordance with local regulations and National Electrical code requirements. Check wiring the connection diagram provided with the generator. The main terminals should be properly spaced for the load connections. Refer to Table 2-2 for proper torque values for the connections. Grounding lug has been provided for properly grounding the system to the generator frame. Grounding wire should be the same size as the main leads.

2.15.7 After all wiring is complete, perform the following checks.

2.15.7.1 Double check all interconnections against the connection diagrams furnished.

2.15.7.2 Remove all tools and shop cloths from the vicinity of the operating equipment.

2.15.7.3 Secure all covers and guards in place.

2.15.7.4 Turn rotor slowly with appropriate starting mechanism (bar engine or flywheel) through one revolution to see that the rotor turns freely. DO NOT PRY ON GENERATOR FAN.

2.15.7.5 Check bearings for the proper lubrication.

2.15.7.6 Determine the direction of the engine rotation and verify with the rotation arrows provided on the generator.

2.15.7.7 Voltage, frequency and phase sequence of power line must agree with the data on generator and control nameplates or connection diagrams.

2.16 PROTECTIVE DEVICES

2.16.1 Engine driven sets must be protected with adequate engine governors and protection against excessive overspeed. Refer to National Electrical Code and local electrical codes for minimum electrical requirements for the generator set.

2.16.2 The output to the load of the generator should always be protected with an overload protection device such as a circuit breaker or fuses. Fuses should be sized using the lowest possible current rating above the full load current rating. 115 percent of rated current is commonly recommended. Size fuses or circuit breaker in accordance with National Electrical Code and Local Electrical Codes.

SECTION 3
OPERATION

3.1 IDLING

Permanent equipment damage can be caused by having the generator set in operating mode while idling the engine. If engine adjustments require that the engine be run at idle speed, the generator set regulating system should be made inoperative by one of the methods that follow.

3.1.1 Where generator set is provided with voltage shutdown switch, be sure switch is set to IDLE position while engine is running at idle speed.

3.1.2 Where generator set is equipped with field circuit breakers, be sure the circuit breaker is set to OFF while engine is running at idle speed.

3.1.3 Where generator set includes an automatic/manual control with switch that has OFF position, be sure switch is set to OFF while engine is running at idle speed.

3.1.4 Where generator set does not include switches described above, remove wires from voltage regulator input terminals during under speed operation of the generator set.

3.1.5 Check for vibration. If excessive, loosen one foot mounting bolt slightly and if vibration decreases, add shims until tightening of the bolt reduces the vibration level. Repeat in turn for all mounting bolts. If vibration levels remain above the allowable limits, recheck the alignment steps outlined in Section 2.

3.2 INITIAL START-UP WITH BOTH AUTO MANUAL AND AUTOMATIC VOLTAGE CONTROL

3.1.1 Generator output must be disconnected from load. Main circuit breaker is open.

3.1.2 Turn voltage adjust rheostat to full counterclockwise.

3.1.3 Actuate auto-manual switch to MANUAL position.

3.1.4 Start the primer mover and bring the set to rated speed. Turn manual voltage adjust rheostat to reach rated voltage. Close output circuit breaker and apply load in steps until rated load is reached. Adjust manual adjust rheostat as necessary to obtain desired output voltage.

3.2.5 Stop unit. This is accomplished by opening the circuit breaker to remove the load. Then stopping the prime mover in accordance with prime mover manufacturer's specifications.

3.2.6 Actuate auto voltage rheostat. Then start engine-generator set and bring to rated speed. Adjust voltage to desired value.

3.2.7 Close output circuit breaker. Then check generator voltage and voltage regulation.

3.2.8 Check for vibration levels at no load and rated load. A slight increase in vibration level from no load to full load is normal. As the load is maintained for 2-3 hours the vibration levels will gradually increase and reach a final level.

CAUTION

Do not actuate auto manual switch with full load applied to generator. Whenever possible, stop the generator prior to switching.

3.3 INITIAL START-UP PROCEDURES FOR GENERATORS WITH AUTOMATIC VOLTAGE CONTROL

NOTE: Unit will have automatic voltage regulator but will not have auto-manual switch.

3.3.1 Generator output must be disconnected from load. Main circuit breaker is open.

3.3.2 Turn auto-voltage adjust rheostat to full counterclockwise position.

3.3.3 Start the prime mover and bring the set to rated speed. Turn voltage adjust rheostat to obtain desired voltage.

3.3.4 Close output circuit breaker and apply load in gradual steps until the rated load is reached. Note voltage regulation with changes in load steps.

3.3.5 Check for vibration levels at no load and rated load. A slight increase in vibration level from no load to full load is normal. As the load is maintained for 2-3 hours the vibration levels will gradually increase and reach a final level.

3.4 FIELD FLASHING

The voltage regulator relies on residual voltage to start the generator action which in turn generates the rated voltage. If the generator fails to generate voltage after it has come up to rated speed, it may be necessary to flash the exciter field. Field flashing must be done while the generator is at a standstill as described in the procedure that follows.

3.4.1 Open the output circuit breaker and stop the engine.

CAUTION
Be sure to maintain polarity (+) to (F+) and (-) to (F-).

3.4.2 Connect the negative lead (-) from a common 12 volt storage battery onto exciter field lead F-.

3.4.3 Connect the positive lead (+) from the battery onto exciter field lead F+. Only a few seconds flashing should be necessary.

3.4.4 Remove battery and connect exciter field leads onto voltage regulator terminals F+ and F-. Be sure to maintain correct polarity.

3.4.5 Start generator and check for satisfactory voltage build up.

3.5 PARALLEL OPERATION

3.5.1 For the generator to operate in parallel with a system in operation the phase sequence of the generator must be the same as the system. Phase sequence check can be made by a phase rotation meter or incandescent lamp methods described in electrical machinery handbooks.

3.5.2 The output voltage at the paralleling point must be the same at each instant which requires that two voltages be of the same frequency, same magnitude and same rotation, and must be in coincidence with each other.

Voltmeters indicate whether the voltage magnitude is the same and frequency meters indicate whether the frequencies are the same. Whether the voltages are in phase and exactly at the same frequency is indicated by a synchroscope or by synchronizing lamps.

A synchroscope can be utilized to indicate the difference in phase angle between incoming machine and the system. If not provided with the set, generator can be paralleled by using incandescent lamps connected as shown in Figure 3-1. The voltage rating of series lamps must equal the voltage rating of the generator.

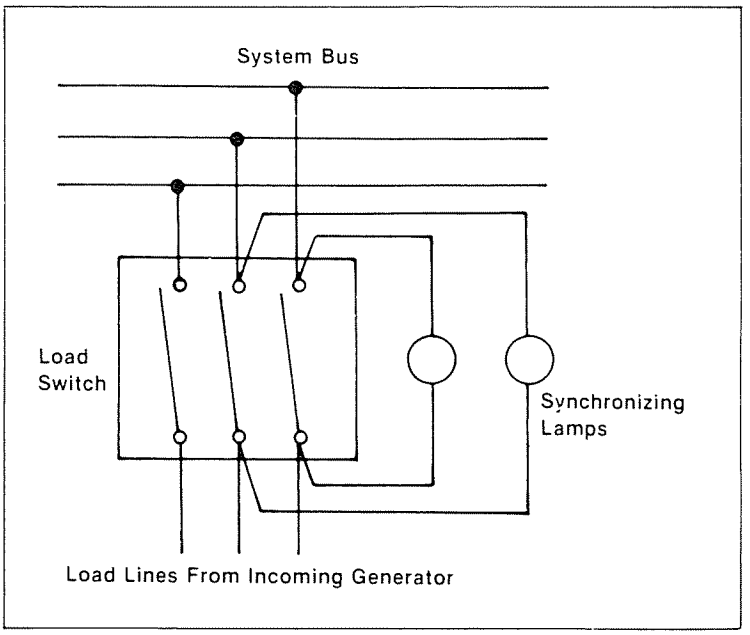

Figure 3-1
Synchronizing Paralleled Generators with Test Lamps

3.5.3 Each prime mover in the system must have the same speed regulating characteristics, and the governors must be adjusted to give the same speed regulation by applying load that is proportional to full load rating of the generator.

3.5.4 Voltage regulator must include paralleling circuitry.

3.5.5 Paralleling current transformers must give the same secondary current.

3.5.6 Current transformer secondary winding provides reactive KVA droop signal to the voltage regulator. Accidental reversal of this electrical wiring will cause the voltage to rise rather than droop. If this occurs during paralleling, stop the unit and reverse the wires at the voltage regulator terminals.

3.5.7 If set is provided with unit/parallel switch, set switch to PARALLEL position on the unit being synchronized.

3.5.8 Synchronize the generator by adjusting speed (frequency) slightly higher than the system. Observe the synchroscope or the lamps. The lamps should fluctuate

from bright to dark at the rate of one cycle every 2 to 3 seconds. When the generator is in phase the lights will be dark, close the circuit breaker. Immediately after closing the breaker measure the line current, Kw and kVAR of the generator. The readings should be within the rating of the unit.

3.5.8.1 A high ammeter reading accompanied by a large Kw reading indicates faulty governor control.

3.5.8.2 A high ammeter reading accompanied by a large kVAR unbalance indicates problems with voltage regulator. Adjustments of the cross current or voltage droop rheostat should improve the phasing of kVAR.

3.5.9 To shut down the generator operating in parallel, gradually reduce the kW load by turning the governor switch to reduced speed. When kW load and line current approach zero, open the generator circuit breaker. Close unit/parallel switch (if generator is so equipped). Operate the generator unloaded for several minutes to dissipate the heat in the winding. Refer to prime mover manual for shut down and cool down procedures.

3.6 CONTINUOUS OPERATION

3.6.1 The generator should be operated within the nameplate values of kW, power factor and voltage. If generator is operate below the rated power factor and voltage, the kVA rating should be decreased to prevent overheating of the field and stator windings.

3.6.2 When generator is carrying unbalanced loads (phase currents varying more than 10 percent of rated value) rotor overheating may result. The rotor heating is caused by negative sequence currents flowing in the field pole face. For a generator guide to the allowable phase unbalance see Figure 3-2, Guide to Allowable Unbalance (which is based on a 10 percent equivalent negative sequence current).

The guide is used in the following manner. Find the point where the vertical line (determined by the maximum current in any of the phases, expressed in percent of rated current) crosses the horizontal line (determined by the minimum current in any of the phases, expressed in percent of rated current). The point where these two lines intersect should be within the permissible "allowable unbalance" region for safe operation of the generator.

3.6.3 Loss of field excitation can result in unit operating out of synchronism with the system when operating is parallel. This will cause damage to rotating rectifiers and severe mechanical stresses on the shaft and other parts. Protective devices should open the generator circuit breaker.

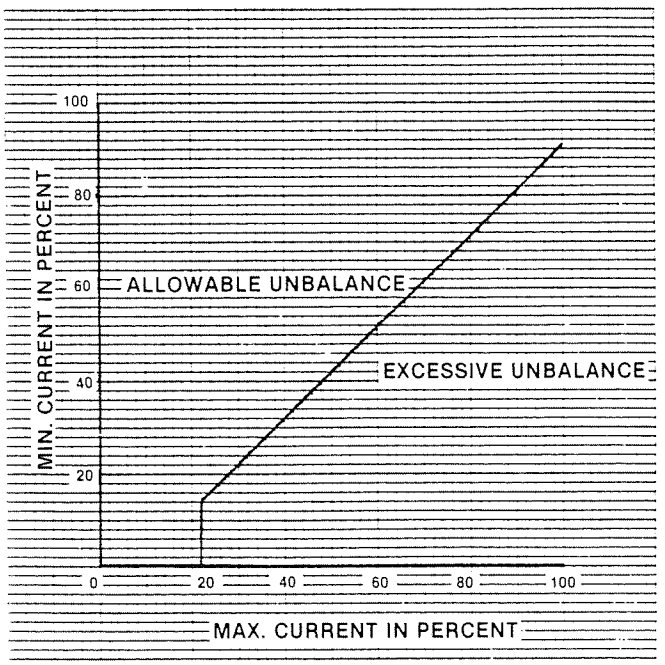

Figure 3-2
Guide to Allowable Phase Unbalance

SECTION 4
MAINTENANCE

4.1 PREVENTIVE MAINTENANCE

4.1.1 Preventive maintenance is the practice of inspecting the generator set, cleaning the generator set, and eliminating minor disorders before they become serious. A routine regular preventive maintenance program practiced conscientiously will ensure peak performance, lengthen the life of the generator, and eliminate or at least greatly reduce breakdown time.

4.1.2 The preventive maintenance schedule described in Table 4-1 is enclosed as a guide for establishing a preventive maintenance program for generators operating under standard conditions. The specific operating conditions should be analyzed by the user of the equipment and a preventive maintenance program established accordingly. When preventive maintenance inspection determines cleaning is necessary, clean the generator and controls as described in paragraph 4.2.1.

4.2 CLEANING

When inspection determines cleaning is necessary, clean the generator and controls as follows.

4.2.1 Wipe loose dirt from exterior painted surfaces of generator, and when incorporated, the generator control panel assembly (controller) with a clean lint free cloth. Remove stubborn accumulations of dirt with an approved detergent or solvent. Clean all ventilating ports with a vacuum cleaner or filtered compressed air at a pressure of from 25 to 40 psi.

WARNING
OBSERVE PRECAUTIONS SPECIFIED BY THE MANUFACTURER OF THE SOLVENT BEING USED.

4.2.2 Clean inside of generator with a vacuum cleaner or use dry filtered compressed air at a pressure of from 25 to 40 psi. Remove stubborn accumulations of dirt and grease from windings with naphtha.

WARNING
Exercise extreme care when using naphtha. Use only in well ventilated areas, away from flame and sparks.

4.2.3 Clean electrical contacts such as relay contacts, switch contacts, and terminals with an approved contact cleaner. **DO NOT FILE CONTACTS.**

4.3 WINDINGS - PROTECTION

Generators operating intermittently in very damp locations should be protected with space heaters. Generators being placed in operation after being subjected to very low temperatures should be slowly warmed to prevent excessive condensation. Winding resistance should be checked before placing the generator in operation if the unit was subjected to an extremely damp environment.

4.4 INSULATION RESISTANCE TEST

A hand cranked megger of not over 500 volts is a convenient and safe method of testing insulation resistance. The following formula is an accepted standard for measuring the insulation resistance of stator windings.

Winding insulation resistance measured at 500 VDC after one minute should not be less than:

$$\text{Resistance in megohms} = \frac{\text{Rated Voltage of Machine} + 1000}{1000}$$

The above formula is satisfactory for most checks. For more information see "Recommended Practice for Insulation Resistance Testing AC Rotating Machinery," AIEE Standard No. 43. **Disconnect load lines and all controls from generator stator leads before testing generator windings.** See Section 2.15.5 for drying methods.

TABLE 4-1

PREVENTIVE MAINTENANCE CHART

1. Lubrication: Lubricate prime mover, gear speed increasers and couplings in accordance with the instructions supplied by the manufacturer of these products. Lubricate Kato generators which have ball or spherical roller bearings as described in paragraph 4.5.1 through 4.5.2.
2. Inspect lead wires and control device wiring for cracked insulation and loose terminals.
3. Clean outside of the generator assembly and ventilation screens. When dust or moisture is excessive, clean and/or dry the inside of the generator assembly.
4. With unit running, observe any unusual noise or vibration. Refer to troubleshooting chart for possible causes of noise and vibration.

4.5 BEARING LUBRICATION

4.5.1 Shielded or Sealed Ball Bearings

Generators under 75 kW have fully shielded or sealed ball bearings. Shielded or sealed ball bearings are factory packed with lubricants and generally can be run several years without requiring replenishment of grease. Should the user decide repacking of the grease is necessary, disassemble machine, clean bearings and repack approximately 1/2 full using a high quality ball bearing grease. Repacking is recommended whenever major repair or overhaul of the generator or its prime mover is done. Grease should be capable of lubricating satisfactorily over a temperature range of: lowest ambient temperature in which generator is operating to plus 250 degrees fahrenheit.

4.5.2 Regreasable Ball or Roller Bearings

Generators larger than 75 kW have regreasable ball bearings and occasionally when design deems it necessary, roller bearings. In applications where regreasable bearings are used, grease fill fittings and grease relief valve will be incorporated in the bearing housing. Lubricate bearings in accordance with the lubricating instructions attached to the generator and the bearing lubrication sheet supplied as supplementary information with this instruction manual.

4.5.3 Oil Lubricated Sleeve Bearing

These bearings should be lubricated in accordance with instructions supplied as supplementary information with this manual.

4.6 TESTING BRUSHLESS EXCITER ROTATING RECTIFIERS WITH AN OHMMETER

If a failure of a rectifier is suspected remove the exciter cover and test rectifiers with an ohmmeter as follows.

4.6.1 Remove nut and washer holding rectifier in heat sink and remove diode lead wire, then lift rectifier from heat sink. Refer to Figure 4-3 (4-4 when unit incorporates dual exciter).

4.6.2 Refer to Figure 4-1, then connect ohmmeter leads across rectifier in one direction. Note meter reading. Reverse leads and note meter reading. The meter should indicate a low resistance when leads are across rectifier in one direction and a high resistance when leads are across rectifier in the other direction.

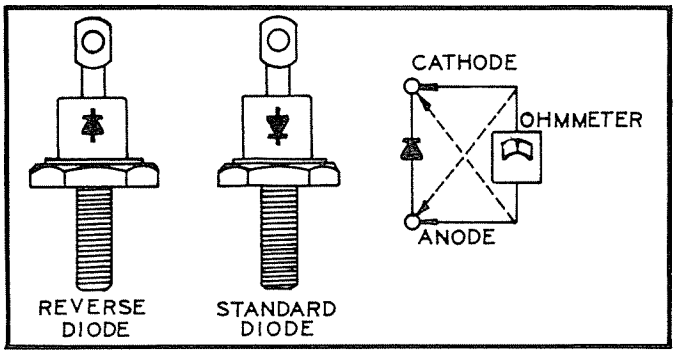

Figure 4-1
Testing Rotating Rectifiers with an Ohmmeter

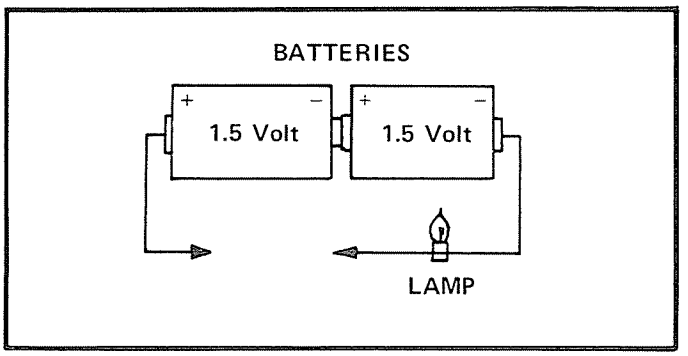

Figure 4-2
Test Lamp

4.6.3 If the meter indicates a low resistance in both directions the rectifier is shorted. A high resistance in both directions indicates an open rectifier.

4.6.4 Replace defective rectifiers with rectifiers of the same operating characteristics as rectifiers installed in the generator at the factory. Order rectifiers by part number including the model and type of the exciter as well as the generator serial number.

4.7 TESTING BRUSHLESS EXCITER ROTATING RECTIFIERS WITH A TEST LAMP

If an ohmmeter is not available, field rectifiers may be tested with a test lamp consisting of standard flashlight batteries and a flashlight bulb as shown in Figure 4-2. Test as follows.

4.7.1 Remove rectifier as described in paragraph 4.6.1.

4.7.2 Connect leads of tester across rectifier in one direction; then reverse leads. The light should light when the leads are across the rectifier in one direction and should not light when placed across rectifier in the other direction.

4.7.3 If the light lights in both directions the rectifier is shorted. If the light does not light in either direction, the rectifier is open.

4.8 TESTING SURGE PROTECTOR WITH TEST LAMP

Refer to Figure 4-2 for test setup. Disconnect one lead and check with lamp tester. The lamp should not light when the test leads are placed across the surge protector in either direction. If the lamp lights, it indicates a shorted surge protector. Replace defective surge protector with one of the same operating characteris-

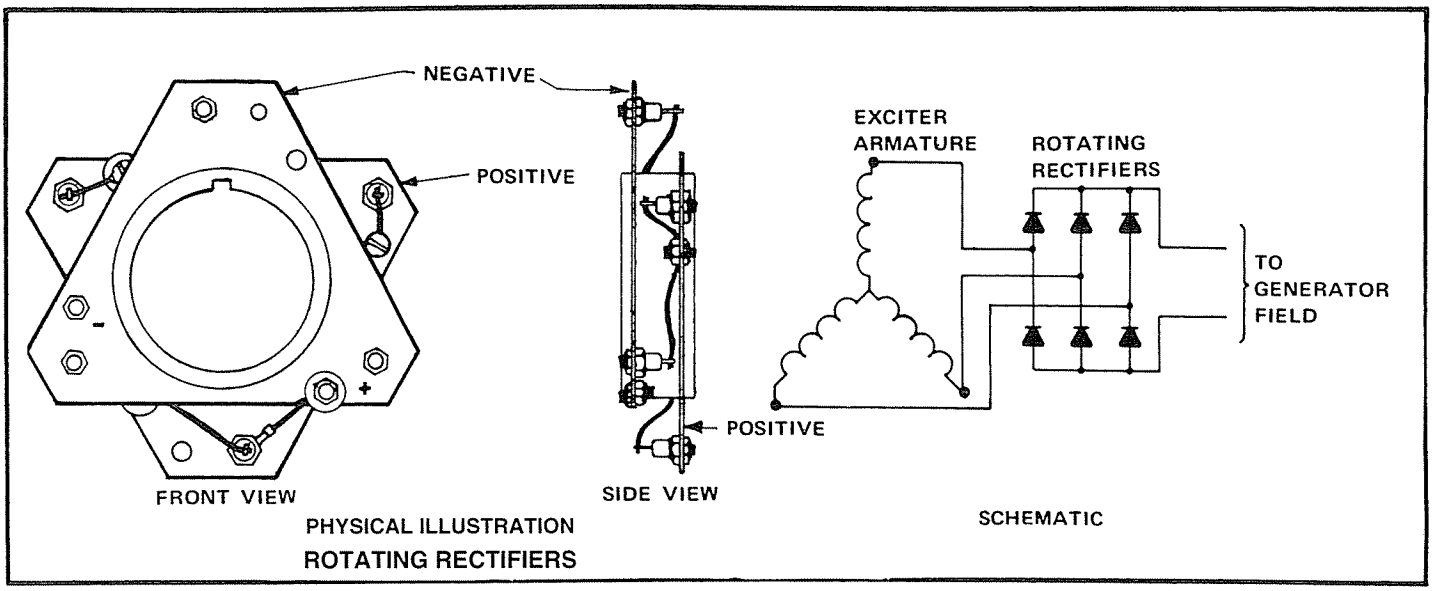

Figure 4-3
Full Wave Rotating Rectifier and Exciter Armature Assembly

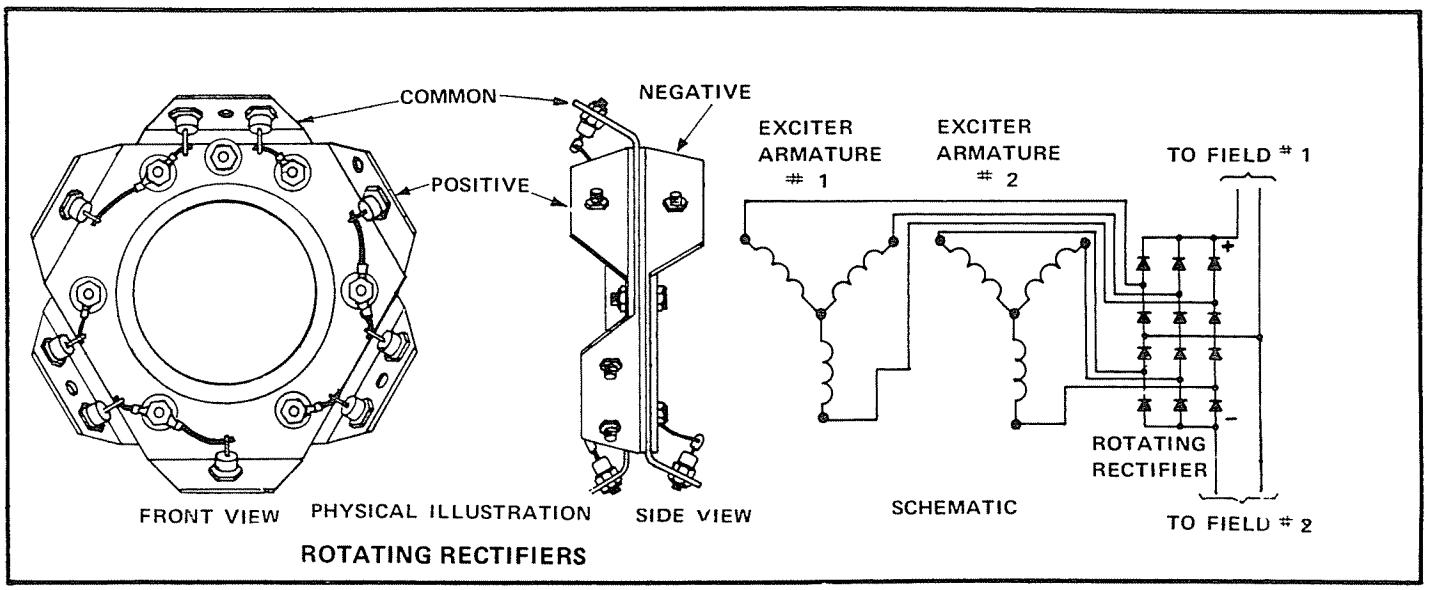

Figure 4-4
Dual Exciter Rotating Rectifier and Exciter Armature Assembly

tics as the surge protector installed in the generator at the factory. Order by part number and include the serial number of the generator. Following replacement of the surge protector, make certain field lead tie-down lacing is securely wound on shaft and tied.

4.9 RESTORING RESIDUAL MAGNETISM

The direct current necessary to magnetize the alternator field is obtained from the exciter. Initially, upon starting the generator, current flow and voltage is induced into the exciter armature by the magnetic lines of force set up by the residual magnetism of the exciter field poles. Residual magnetism of the exciter field poles may be lost or weakened by a momentary reversal of the field connection, a strong neutralizing magnetic field from any source, or if the generator is not operated for a long period of time. To restore the small amount of residual magnetism necessary to begin the voltage build up, connect a battery of from 6 to 32 volts to the exciter field coil circuit. Normally a battery of 6 to 12 voltage is large enough. When the field windings have a high resistance (75-100 ohms) a larger battery voltage may be required. Connect the battery and flash field as follows:

4.9.1 Disconnect exciter field coil wire F2 at terminal F2.

4.9.2 Connect battery positive lead to field coil lead F2.

4.9.3 Flash field by touching battery negative lead to field coil circuit terminal F1.

4.9.4 Disconnect battery leads.

4.9.5 Reconnect field coil lead F2 to terminal F2 and F1 to terminal F1.

4.9.6 Start unit and observe generator build up. Reflash field (paragraphs 4.9.1 through 4.9.5 above) if generator output voltage does not build up.

NOTE

If the polarity of the exciter is reversed by flashing the field, it may be corrected by interchanging the battery leads.

SECTION 5
TROUBLESHOOTING

5.1 Troubleshooting is the process of recognizing malfunctions of the system, intelligently analyzing the malfunction, and making the necessary corrections to place the unit back into proper operation.

5.2 Between regular preventive maintenance inspections, be alert for any signs of generator set trouble. Common symptoms as well as the probable cause and possible remedy are listed in Table 5-1. Correct any minor trouble immediately. **Minor defects left uncorrected can cause serious damage which can result in costly repairs and down time.**

TABLE 5-1
TROUBLESHOOTING CHART

SYMPTOM	POSSIBLE CAUSES	REMEDY
No Voltage	Open circuit breaker or fuses (if voltage is sampled on load side of fuses or circuit breaker).	Check. Reset circuit breaker or replace fuses if open.
	Overvoltage, undervoltage, or overload devices tripped (when protective devices incorporated in circuit).	Check for cause of abnormal condition. Correct any deficiencies. Reset devices. Check Generator Nameplate for nominal operating values.
	Open circuit in exciter field.	Check out continuity of shunt field and leads to voltage control. (Use ohmmeter or wheatstone bridge.) If open in field coils, remove exciter field assembly and return assembly to factory for repair.
	Loss of residual magnetism in exciter field poles or a model voltage regulator is used which requires field flashing to bring generator voltage to level where regulator will operate.	Adjust manual adjust potentiometer to full resistance. Flash field by making a flash connection of DC across terminals F1 to F2. See "Restoring Residual Magnetism." When voltage regulator is such that flashing is required install automatic field flashing system.
	Open circuit in stator windings.	Check for continuity in windings. Return to factory for repair if open.
	Open circuited manual field rectifiers.	Check rectifiers, replace faulty diodes or rectifier assembly.
	Open circuit in manual voltage adjust circuit.	Check potentiometer for continuity. Replace if open circuit.
	Malfunction of automatic voltage regulator.	See troubleshooting of voltage regulator. Correct deficiencies.
	Short circuited generator output leads.	Clear lead to restore voltage build up.

TABLE 5-1 (CONTINUED)

SYMPTOM	POSSIBLE CAUSES	REMEDY
No Voltage (cont.)	Open in rotating rectifiers.	Check rotating rectifiers and replace if open.
	Open in alternator field.	Check for continuity and return rotor to factory for repair if field coils are open.
	Shorted surge protector.	Check for shorts and replace.
	Shorted rotating rectifiers.	Check for shorts. Replace if shorted or open.
	Shorted exciter armature.	Check for short. Replace if shorted.
	Shorted leads between exciter armature and generator field.	Test and repair.
Low Voltage	Defective voltage regulator (when used).	Check regulator, adjust or repair or replace if defective.
	Automatic field flashing system required.	Contact Kato Engineering. Describe system and model of voltage regulator used.
	Defective rectifiers in stationary rectifier assembly (when used).	Check rectifier assembly. Replace defective rectifier.
	Improper adjustment of voltage adjust rheostat.	Adjust rheostat.
	Excessive load.	Reduce load. With 3 wire, single phase and 4 wire, three phase generators, the load on each leg should be as evenly balanced as possible and should not exceed the rated current on any leg.
	Line loss.	Increase size of line wire.
	High resistance connections. Connections will be warm or hot.	Make better connections.
	Shorted field.	Test field coils for possible short by checking resistance with an ohmmeter or resistance bridge. Return rotor assembly to factory for repair if alternator field coils are shorted.
	Low power factor.	Reduce inductive (motor) load. Some AC motors draw approximately the same current regardless of load. Do not use motors of larger horsepower rating than is necessary to carry the mechanical load.

TABLE 5-1 (CONTINUED)

SYMPTOM	POSSIBLE CAUSES	REMEDY
Low Voltage (cont.)	Weak field due to operating in warm temperature.	Improve the ventilation of generator. Field current can be increased providing the generator temperature rating stamped on the nameplate is not exceeded.
	Improper voltage and/or frequency to drive motor causing low speed.	Check input voltage. Correct deficiencies. Check motor data plate for nominal operating values.
	Excessive load.	Reduce load to rated value.
	Defective bearing.	Replace bearing.
	Low speed due to improper belt adjustment on belt drive motor-generator sets.	Align and adjust belt. Replace if worn excessively. Check for proper sheave size.
	Improper speed of engine driven generator set due to defective governor, ignition system, or carburetor.	Check and correct deficiencies.
Fluctuating Voltage	Voltage regulator not operating properly (if used).	Check regulator. Repair or replace if defective.
	Prime mover speed fluctuating.	Check frequency and voltage of incoming power when generator set is motor driven. Engine governor on engine driven generator sets.
	Loose internal or load connections.	Make better connections.
	Generator overloaded.	Reduce load to rated value.
	DC excitation voltage fluctuating.	Trace DC excitation circuit. Correct any defects.
High Voltage	Overspeed.	Correct speed of prime mover.
	Improper adjustment of voltage adjust rheostat or voltage regulator.	Adjust rheostat and/or voltage regulator.
Overheating	Clogged ventilating screens and air passages.	Clean all screens and air passages.
	Dry or defective bearings.	Replace defective bearings.
	Coupling misaligned or on belt driven generators, belt too tight.	Align generator set or adjust belt.

TABLE 5-1 (CONTINUED)

SYMPTOM	POSSIBLE CAUSES	REMEDY
Overheating (cont.)	Generator field coils shorted or grounded.	Test field coils for shorts. Replace shorted rotor or return to factory for repair.
Vibration	Defective or dry bearings.	Replace defective bearings.
	Misalignment of generator and prime mover.	Align generator set.
	Generator not properly mounted.	Check mounting. Correct defective mounting.
	Transfer of vibration to generator from another source.	Isolate generator set from source of vibration by installing vibration dampeners between the generator set base and foundation.

SECTION 6
ASSEMBLY AND DISASSEMBLY

6.1 BEARING REMOVAL

Remove the endbell to expose bearings. Use a puller to remove the bearing from the shaft end with a cap. If the bearing is going to be used again, make certain puller applies pressure only against the bearing inner ring (see Figure 6-1).

6.2 BEARING INSTALLATION

Heat the bearing to a temperature of from 220 degrees fahrenheit to 250 degrees fahrenheit in a clean thermostatically controlled oven. Start the heated bearing into the shaft. Then use a fiber or soft metal tube to tap bearing into place. See Figure 6-2. Make certain that pressure is applied only to the bearing inner ring. Press bearing onto shaft until inner ring is against bearing shoulder on the shaft. Assemble the generator after the bearing has cooled.

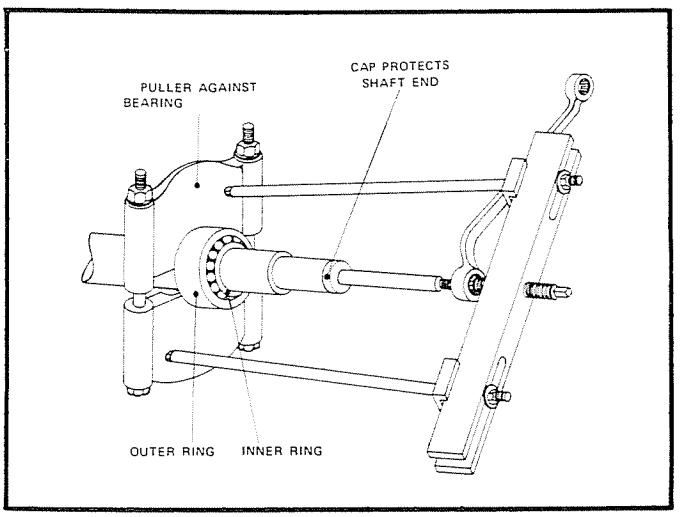

Figure 6-1
Removing Bearing from Generator Shaft

6.3 EXCITER ARMATURE AND ROTATING RECTIFIER ASSEMBLY REMOVAL

Remove exciter armature and rotating rectifier bridge assembly as a unit as described in the following general instructions.

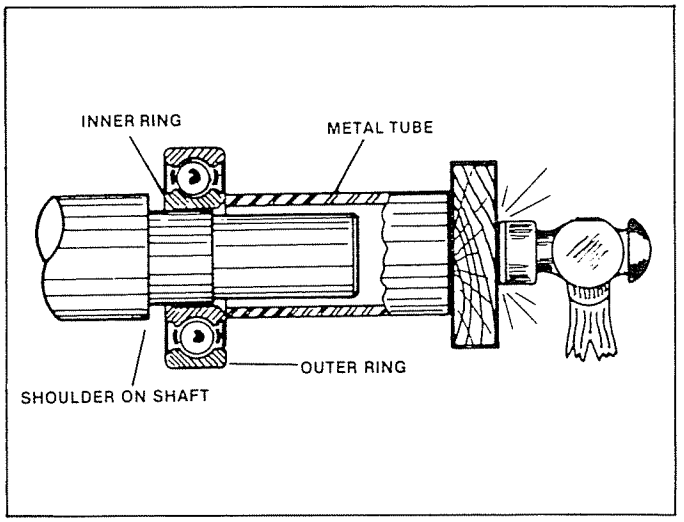

Figure 6-2
Installing Bearing on Generator Shaft

6.3.1 Remove exciter cover. Disconnect alternator field leads from positive (+) and negative (-) terminals located on the heat sinks of the rotating rectifier assembly. Remove exciter armature retaining bolt and washer.

6.3.2 The exciter armature is a "slip fit" on the generator shaft. If the armature cannot be removed by hand, remove with a puller installed as described in paragraph 6.3.3.

CAUTION
DO NOT PULL ON ROTATING RECTIFIER ASSEMBLY OF THE EXCITER ARMATURE WINDINGS.

6.3.3 Install a cap or plug to protect the shaft center. Utilizing the tapped holes in the end of sleeve, bolt to the end of the sleeve spacers and a metal plate. Refer to Figure 6-3 for fixture setup.

6.3.4 Hook a bearing puller to the metal plate and pull exciter armature and rotating rectifier assembly from the shaft.

6.4 EXCITER ARMATURE AND ROTATING RECTIFIER ASSEMBLY INSTALLATION

Install exciter armature and rotating rectifier assembly as a unit as described in the following general instructions.

6.4.1 If the "slip fit" exciter armature and rotating assembly will not easily slide onto the shaft by hand, install with a fixture as shown in Figure 6-4 and described in paragraph 6.4.2.

NOTE

Usually the exciter armature will slide onto the shaft most of the way by hand. The exciter armature can usually be "seated" by tapping lightly on the sleeve with a soft rubber or fiber mallet. MAKE CERTAIN MALLET HITS ONLY THE SLEEVE, NOT RECTIFIER ASSEMBLY OR ARMATURE WINDINGS.

CAUTION

If exciter armature is aligned and locked in place by a removable key, make certain the key is in place in the generator shaft and the keyway in the exciter armature sleeve is aligned with key before starting the exciter armature onto generator shaft.

If unit uses an aligning lug on the exciter armature sleeve and a slot in the generator shaft rather than a removable key to align and lock the exciter armature on the shaft, make certain lug and slot are aligned and engaged.

6.4.2 Refer to Figure 6-4 for fixture setup. Start exciter armature and rectifier bridge on shaft. Thread stud in rotor shaft. Install large diameter washers on stud and start stud nut. Pull exciter armature and rotating rectifier onto shaft by turning stud nut.

6.4.3 Install exciter armature retaining bolt and washer. Connect alternator field leads to positive (+) and negative (-) terminals located on the heat sinks of the rotating rectifier assembly. Install exciter cover.

6.5 REMOVING AND REPLACING EXCITER STATOR ASSEMBLY

Should it be necessary to remove the exciter stator assembly, refer to "Generator Disassembly" procedures and then remove stator as described in the following general instructions.

6.5.1 Remove exciter cover and exciter armature. Refer to paragraphs under 6.4.

6.5.2 Disconnect exciter field leads F1 and F2. Remove any clips securing exciter field leads to the exciter frame, generator frame or the endbell.

6.5.3 Remove generator exciter and generator endbell. Refer to "Generator Disassembly" procedures. Check for shims in endbell bearing well. Make certain the shims, if incorporated, are reinstalled when generator is reassembled.

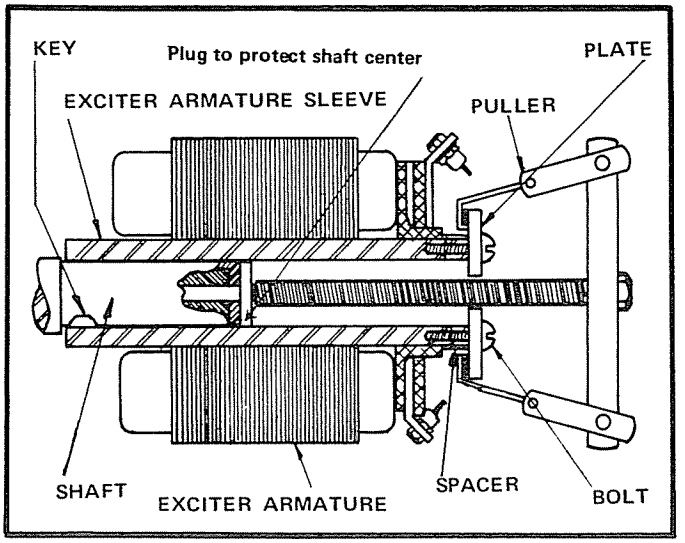

Figure 6-3
Removing Exciter Armature and Rotating Rectifier Assembly

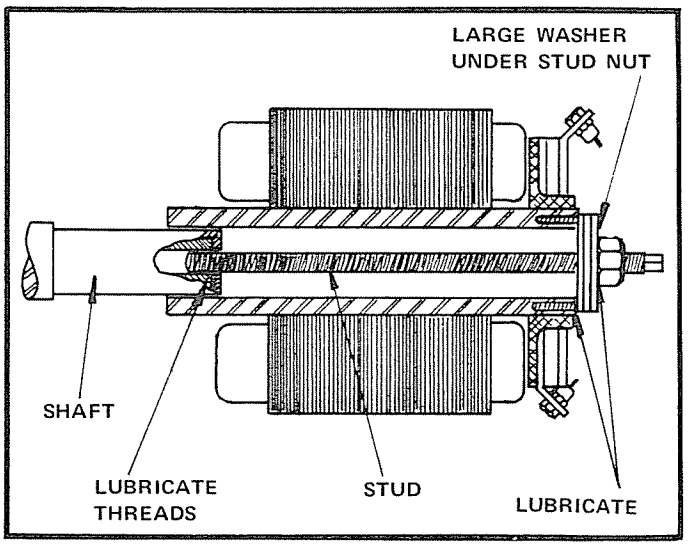

Figure 6-4
Installing Exciter Armature and Rotating Rectifier Assembly

6.5.4 Remove bolts securing exciter frame and stator to the endbell.

6.5.5 Assembly exciter stator by reversing disassembly procedures.

NOTE

Install exciter stator with its field leads toward generator endbell.

6.6 ASSEMBLY AND DISASSEMBLY OF SINGLE BEARING ENGINE DRIVEN GENERATOR

Refer to Figures 6-5a and 6-5b for part identification, then disassemble generator as described in the following general instructions.

6.6.1 Remove terminal box cover and disconnect generator load leads and exciter field leads. Tag leads and terminals to make certain leads are correctly connected when unit is reassembled.

6.6.2 Remove fan screen. Remove bolts securing drive disks (20) to engine flywheel. Remove bolts securing engine flywheel housing to generator adaptor endbell (17).

6.6.3 Remove bolts securing generator base pads (16) to engine-generator base or foundation.

6.6.4 Move generator to location affording sufficient room for disassembly. Attach slings to lifting eye bolts (13) to move generator. See Section 2 "Installation" instructions for handling precautions.

6.6.5 Remove drive disk bolts (18). Remove drive disks (20).

6.6.6 Remove exciter cover (1). Disconnect alternator field leads, remove exciter armature retaining bolt and washer (2). Remove exciter armature and rotating rectifier assembly as a unit. See paragraphs in 6.4.

6.6.7 Remove clips securing exciter field leads to exciter frame, generator frame and generator endbell.

6.6.8 Remove endbell bolts (9). Remove endbell (10). Tap lightly with rubber or fiber mallet to loosen endbell. Check for shims in the endbell bearing housing (well). Make certain shims, when incorporated, are reinstalled when unit is assembled.

6.6.9 If the exciter stator (field) (5) requires repair or replacement, remove bolts (7) and remove exciter frame and stator assembly (5) from endbell (10).

6.6.10 Install pipes over generator shaft on the drive and exciter end of rotor. Attach slings and hoist to pipes and remove rotor assembly (12) from stator and frame (11). Make certain air gap is maintained between the rotor and stator during removal of the rotor.

CAUTION

Make certain pipes are of sufficient strength to support weight or rotor and that pipes do not have rough edges which would damage shaft surface.

6.6.11 If bearings require replacement, remove bearings as described in paragraph 6.1.

6.6.12 Assemble generator by reversing order of disassembly procedures listed above (paragraphs 6.6.11 through 6.6.1). Assemble to engine as described in Section 2.

NOTE

Install bearings as described in paragraph 6.2 and exciter as described in paragraphs under 6.4 and 6.5. Make certain generator field is aligned with generator armature (stator) and the exciter armature is aligned with the exciter field.

6.7 ASSEMBLY AND DISASSEMBLY OF TWO BEARING GENERATOR

Refer to Figures 6-6a and 6-6b for part identification and then disassemble generator as described in the following general instructions.

6.7.1 Remove terminal box cover and disconnect generator load leads and exciter field leads. Tag leads and terminals to make certain leads are correctly connected when unit is reassembled.

6.7.2 Remove coupling or sheaves in accordance with manufacturer's instructions.

6.7.3 Remove bolts securing generator base pads (16) to base or foundation.

6.7.4 Move generator to location affording sufficient room for disassembly. Attach slings to lifting eye bolts (13) to move generator. See Section 2 "Installation" instructions for handling precautions.

6.7.5 Remove exciter cover (1). Disconnect alternator field leads, remove exciter armature retaining bolt and washer (2). Remove exciter armature and rotating rectifier assembly as a unit (see paragraphs under 6.3).

6.7.6 Remove clips securing exciter field leads to exciter frame, generator frame and generator endbell.

6.7.7 Remove endbell bolts (9). Remove endbell (10). Tap lightly with rubber or fiber mallet to loosen

These drawings are intended for purposes of discussion only and may differ slightly from the actual construction of the unit.

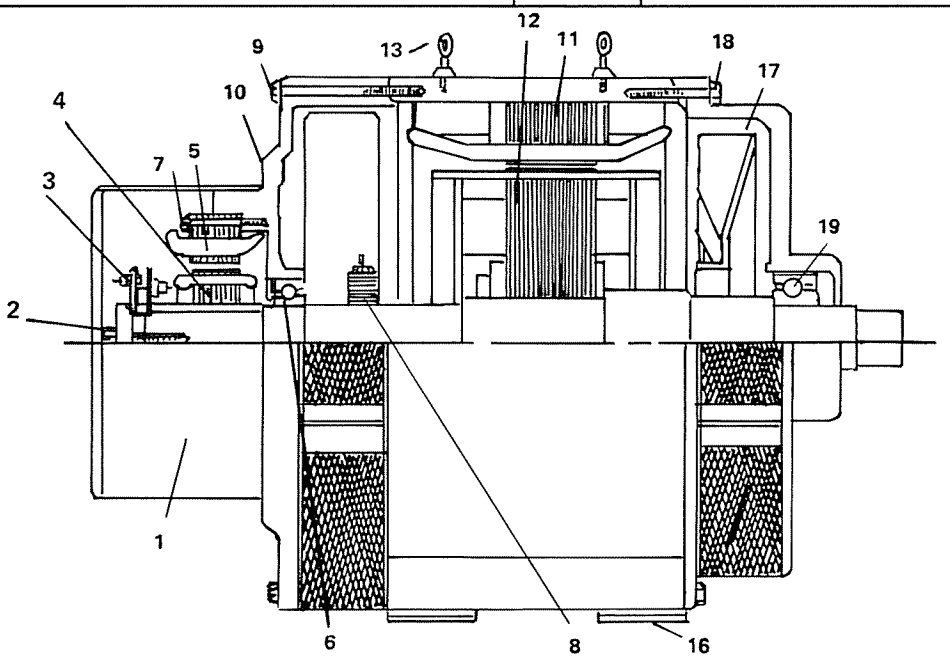

FIGURE 6-6B TYPICAL KATO TWO-BEARING REVOLVING FIELD GENERATOR WITH OUTBOARD EXCITER FIELD MOUNTED ON ENDBELL

endbell. Check for shims in the endbell bearing housing (well). Make certain shims, when incorporated, are reinstalled when unit is assembled.

6.7.8 If the exciter stator (field) (5) requires repair or replacement, remove bolts (7) and remove exciter frame and stator assembly (5) from endbell (10).

6.7.9 Remove endbell bolts (18) and endbell (17). Check for shims in bearing well (see paragraph 6.7.7).

6.7.10 Remove fan (14) from hub (15).

NOTE

Before loosening fan, measure distance from fan to fan baffle and maintain this distance when fan is reinstalled.

6.7.11 Install pipes over generator shaft on the drive and exciter end of rotor. Attach slings and hoist to pipes and remove rotor assembly (12) from stator and frame (11). Make certain air gap is maintained between the rotor and stator during removal of the rotor.

CAUTION

Make certain pipes are of sufficient strength to support weight of rotor and that pipes do not have rough edges which would damage shaft surface.

6.7.12 Assemble generator by reversing order of disassembly procedures listed above (paragraphs 6.7.11 through 6.7.1).

NOTE

Install bearings as described in paragraph 6.2 and exciter as described in paragraphs under 6.4 and 6.5. Make certain generator field (rotor) is aligned with generator armature (stator).

6.8 ASSEMBLY AND DISASSEMBLY OF SYNCHRONOUS BRUSHLESS DUAL GENERATORS FAN MOUNTED AT DRIVE END

Refer to Figure 6-7 for part identification and then disassemble generator as described in paragraphs under 6.7. Assemble generator by reversing disassembly procedures listed in paragraphs under 6.7.

6.9 ASSEMBLY AND DISASSEMBLY OF SYNCHRONOUS BRUSHLESS DUAL GENERATORS WITH CENTER MOUNTED FAN

Refer to Figure 6-8 for part identification, then disassemble generator as listed in the following general instructions.

6.9.1 Disconnect generator and proceed with disassembly and described in 6.7 paragraphs 6.7.1 through 6.7.6.

6.9.2 Remove fan screen. Remove fan blades from fan hub. Mark each blade and the fan hub for direction of rotation. Number the fan blades and the fan hub as each blade segment is removed to ensure proper reinstallation.

NOTE

Fan blades must be reinstalled in the correct direction of rotation. The rotor assembly was factory balanced with fan blades installed. Each blade segment must be reinstalled to the identical position on the hub as when removed. Blades and hub must be clearly marked during disassembly to ensure correct reassembly.

6.9.3 When removal of fan blades and identification marking of blades and hub is complete and satisfactory, proceed with disassembly of the generator as described in 6.7 paragraphs 6.7.7 through 6.7.12.

6.9.4 Reassemble generator by reversing order of steps followed to disassemble the unit. Make certain fan blades are correctly installed.

NOTE

Install bearing as described in paragraph 6.2 and install exciter as described in paragraphs under 6.4 and 6.5. Make certain generator field (rotor) is aligned with generator armature (stator) and the exciter armature is aligned with exciter field.

These drawings are intended for purposes of discussion only and may differ slightly from the actual construction of the unit.

SECTION 7
RENEWAL PARTS ORDERING INFORMATION

Renewal parts must be of the same physical construction and have the same operating characteristics as parts installed in the generator at the factory. Do not attempt to substitute "similar" parts. Order parts by part name and part number. As additional information always include the generator serial number and the generator and exciter type and model numbers. For fastest service direct parts order to Kato Engineering, Product Service Department, P. O. Box 47, Mankato, Minnesota, 56002.

WARRANTY

Kato Engineering warrants that its products will perform as specified in bonafide quotations or Kato publications, providing such products are properly installed, properly cared for, and properly operated under normal environmental conditions.

Standard products manufactured by Kato Engineering are warranted to be free from defects in workmanship and material for a period of one year in operation of 18 months from date of shipment, and any products which are defective in workmanship or material will be repaired or replaced at the option of Kato Engineering. Final determination as to whether a product is actually defective rests with Kato Engineering. The obligation of Kato Engineering hereunder shall be limited solely to repair and replacement at its factory, products that fall within the foregoing limitations and shall be conditioned upon receipt by Kato Engineering of written notice within the warranty period of any alleged defects of deficiency. No products shall be returned to Kato Engineering without its prior consent. In no case will Kato Engineering accept shipping charges incurred either through return of defective items to its factory or return of repaired or replacement items to the user. Kato Engineering cannot assume responsibility or accept invoices for unauthorized repairs to its components even though defective. In the case of components, parts or units purchased by Kato Engineering the obligation of Kato Engineering shall not exceed the settlement that it is able to obtain from the supplier thereof.

The life of the products of Kato Engineering depends to a large extent upon the type of usage. Kato Engineering makes no warranty as to period of service or as to fitness of its products for specific applications by the buyer. In no event will Kato Engineering be liable for consequential or incidental damages or any expense incurred by the Buyer due to use or sale of products sold by Kato Engineering.

The foregoing warranty is exclusive and in lieu of all other warranties expressed or implied, including but not limited to any warranty of merchantability or of fitness for a particular purpose.

This warranty does not apply to experimental or developmental products.

Safety Summary

WARNING

This equipment contains high speed (1800 RPM) rotating parts and develops lethal voltage (480 VAC or higher). Stop generator set before removing protective covers for the purpose of making electrical connections, installation, adjustments, inspection, troubleshooting, testing, repair, or parts replacement. Install protective covers before starting the generator set. Failure to observe this precaution can result in serious injury or electrocution.

WARNING

Where meters or test instruments are used for purpose of troubleshooting and testing, it is recommended the test equipment be placed external to the generator and the generator set be stopped while making or removing meter and instrument connections. Be sure protective covers are installed before running unit. Failure to observe this precaution can result in serious injury or electrocution.

WARNING

Do not lift complete generator set by means of lifting eye on generator. Disregarding these instructions may result in serious injury or equipment damage.

WARNING

Do not lift or pry on generator fan. Failure to observe this precaution can result in serious injury and equipment damage.

WARNING

Make certain that sufficient clearance exists between fan and stationary parts and make certain fan and fan hub bolts are torqued. Failure to observe this precaution can result in serious injury and equipment damage.

WARNING

When circuit breakers are not included with the generator, the terminals on the ends of the stator lead wires are not insulated. These terminals must be insulated before generator set is operated. Failure to observe this precaution can result in serious injury and equipment damage.

CAUTION

Do not attempt to lift or transport any single bearing generator without proper rotor support. Failure to observe this precaution can result in extensive equipment damage. Make certain exciter rotor is removed while handling generator.

CAUTION

Do not push on rotating rectifier or exciter winding. Failure to observe this precaution can result in equipment damage.

SECTION 1
GENERAL INFORMATION, PRINCIPLES OF OPERATION AND MECHANICAL CONSTRUCTION

GENERAL

KAMAG AC generators are brushless 4-pole machines producing 60 Hz power at 1800 rpm or 50 Hz power at 1500 rpm. The generators are of the revolving field type, having rotating field poles called the rotor and a stationary armature called the stator. All standard units are broad voltage range machines that have twelve lead wires brought out from the stator coil groups. This feature permits connection of the stator winding in either three-phase wye, three-phase delta, or single-phase configuration. Table 1 lists the voltages that can be obtained from the output of KAMAG generators.

Single bearing generators are supplied with an SAE adapter and flexible drive disks on the drive end of the unit. Alignment of the generator frame and engine is ensured by the concentricity of the flywheel housing and the generator adapter, while alignment of the generator rotor and engine crankshaft is ensured by the concentricity of the drive disks and engine flywheel.

Drawings and tables are contained in Section 10 in this manual.

The major parts comprising the KAMAG generator are shown on Figure 1. Figure 10 is an electrical schematic of the generator field and exciter. The twelve stator lead wires and respective stator coil groups are shown on Figure 11.

PRINCIPLES OF OPERATION

Ac generators require direct current flowing through the field winding to set up the magnetic flux which generates ac power in the stator winding. An exciter, which is a small ac generator with rectified output, provides this direct current. While the generator armature is stationary and the field rotates, the exciter field is stationary and the armature and rectifier rotate.

The exciter itself requires direct current for excitation. This excitation may be provided by any dc power supply that provides the proper excitation. However, in order to keep the generator output voltage relatively constant, the dc excitation must be automatically regulated by means of a voltage regulator.

The voltage regulator provides regulated dc excitation. This device measures the generator voltage and compares the measured voltage with a pre-set voltage extablished by adjustment of a voltage adjust potentiometer or rheostat. It then uses the result of the comparative process to automatically control the excitation supplied to the exciter field winding. This action in turn regulates the excitation applied to the generator field winding, which controls the magnetic flux and thereby the ac power generated by the generator stator winding.

The voltage regulator requires electrical power for operation of its circuitry. Usually a portion of the power generated by the generator is used to power the voltage regulator.

MECHANICAL CONSTRUCTION

The major parts comprising the KAMAG generator are shown in Figure 1 and described in the paragraphs that follow.

Generator Frame and Stator

Rectangular steel bars welded to endrings provide rigid support for the stator, the generator endbell, and the adapter. Weldments rigidly secure the stator to the frame bars.

The stator core is composed of a stack of thin, notched electrical steel laminations assembled under pressure and welded to the frame bars. The semi-closed notched slots are Class F insulated; random wound coils are firmly wedged in the insulated slots. The stator coils in KAMAG generators are connected in three-phase groups with twelve lead wires that terminate within the terminal box. Stator wire connections are insulated and the entire stator is then impregnated with thermo-setting 100 percent solid bonding epoxy and baked under a controlled cycle. This process minimizes voids and ensures high dielectric strength and excellent moisture resistance.

Generator Frame Cover

A removable sheet metal cover encloses the generator frame.

Generator Rotor Assembly

A precision machined steel shaft, the four-pole rotating field, the exciter armature and the rotating rectifier comprise the rotor assembly. Also mounted on the shaft and provided with a replacement rotor are the drive hub and the generator bearing. A two-section fan mounts on the rotor at the adapter end of the generator.

Katolight Service - Master Repair Manual - Page 582

A. Shaft

The rotor shaft includes a keyway and key at the drive end for mounting the drive hub, a keyway and key for mounting the rotor field core, and a keyway and key for mounting the exciter armature and rotating rectifier.

B. Generator Field Poles

The four poles which carry the field windings are comprised of a stack of one-piece electrical steel laminations press-fitted together using a hydraulic press. Copper rods of the amortisseur winding are pressed into circular holes through the pole head portion of the core structure and welded to copper end plates that form the front and back section of the assembled field core structure. The field core structure is pressed on the shaft using a high pressure hydraulic press and keyed, forming a rigid rotating element. Round steel studs are pressed into each pole head for attachment of rotor balance rings at the front and back section of the field assembly.

Heavily insulated series-connected field coils are wound about the four poles. A support block made of insulating material provides coil support at the bottom and top of the field coil. Two lead wires are brought out to the rotating rectifier.

A thermo-setting epoxy is applied to the completed generator field assembly and the field assembly is baked under a controlled cycle to ensure high dielectric strength and mechanical strength.

C. Driving Hub and Drive Disks

The KAMAG single bearing generator is fitted with a precision machined interference fit drive hub that is keyed to the shaft. This hub carries a number of flexible steel drive disks which have holes for fastening to the flywheel. The outside and inside diameter are precision machined and bolt holes are precision located and drilled, ensuring concentric alignment with the drive hub and the engine flywheel. Ring shaped steel spacers used between the hub and disks provide a small amount of field adjustment to maintain proper alignment.

D. Air Circulating Fan

The fan consists of two half-sections that clamp together and are held securely in place on the shaft by two steel bolts. The fan mounts at the drive end of the generator between the drive hub and the generator field poles.

Ambient air is drawn into the outboard end of the generator, and passes over the exciter, across the outside of the generator stator windings and stator laminations, and through the air gap between the generator stator and field poles. This circulation of air removes heat from the windings and laminations. The cooling fan exhausts the heated air from the generator.

E. Bearing

Single bearing KAMAG generators have a duty-selected shielded ball bearing located at the outboard end of the generator. The bearing outer race is supported within a machined bearing housing located in the center of the endbell, while the inner race fits onto a machined section on the generator shaft. The bearing is factory packed with lubricating grease.

Exciter Rotor

The exciter rotor consists of the exciter armature wound with a three-phase winding and a full-wave rotating rectifier. Three-lead wires, one from each phase of the exciter armature winding, connect to the rectifier diodes as shown on Figure 11. The direct current from the rotating rectifier is conducted to the generator field through lead wires.

Two bolts mount the rectifier assembly to the exciter armature core structure. The entire exciter rotor unit slides over the generator shaft and is held in place by a rectangular key located in the shaft keyway and a retaining bolt and washer at the outboard end of the shaft as shown on Figure 2.

A. Exciter Armature

The exciter armature core structure is comprised of a stack of thin, notched, one-piece laminations held assembled under pressure and kept compressed and aligned by steel rivets through the stack of laminations. The semi-closed slots are insulated with Class F insulation, and the coils of the three-phase exciter armature

winding are then securely wedged in the slots. The entire exciter armature is completely impregnated with thermo-setting epoxy and baked under a controlled cycle. Three lead wires, one from each phase of the exciter armature winding, connect to the rotating rectifier as shown on Figure 11.

B. Rectifier

The exciter armature three-phase ac output is applied to a full-wave rectifier comprised of a positive heat sink, a negative heat sink, a molded insulating plate, a metal plate, three forward polarity diodes, three reverse polarity diodes, and a surge suppressor. The heat sinks are molded onto the insulating plate. The three forward polarity diodes mount on the positive heat sink, while the three reverse polarity diodes mount on the negative heat sink. A surge suppressor is mounted across the heat sinks. A generator field lead wire attaches to the positive heat sink while the second generator field lead attaches to the negative heat sink. This rectifier output circuit provides excitation to the series-connected generator field winding. Three wires, one from each phase of the exciter armature winding, attach to the diodes as shown in Figure 11. The complete rectifier assembly is held in place on the exciter armature by two bolts.

Exciter Field Assembly

The exciter field core structure is comprised of a stack of thin, notched electrical steel laminations that are held axially and tangentially aligned by a weldment across the stack of laminations. The steel laminations are of the type that retain residual magnetism. This residual magnetism produces a magnetic field which, when the generator is started, induces current in the exciter armature, providing the generator field with sufficient dc excitation for generator voltage build-up.

The slots in the exciter field core structure are insulated with Class F insulation and the coils are then firmly wedged in the slots. The coils are series connected; lead wires are brought out for connection to the voltage regulator dc output. The entire exciter field assembly is completely impregnated with thermo-setting epoxy and baked under a controlled cycle. Bolts that pass through holes in the exciter field core structure and thread into tapped holes in the bosses located on the generator endbell provide rigid mounting and ensure concentric alignment.

Endbell

A cast iron endbell encloses the outboard end of the generator. Precision machined matching pilot and recess on the endbell and generator frame endring ensure concentric alignment with the generator frame. The endbell is rigidly secured to the frame by bolts that pass through holes in the terminal box and in the endbell and thread into tapped holes in the frame endring. A machined bearing housing at the center of the endbell supports the outer race of the generator bearing while raised bosses with tapped holes provide mounting for the exciter field assembly.

Adapter

A cast iron adapter at the drive end of the generator mounts to the engine flywheel housing while the inboard side of the adapter mounts to the generator frame endring. The face on both the inboard and outboard surfaces are precision machined with pilot or recess to ensure concentric alignment with the generator frame and the engine flywheel housing. Bolts that pass through the holes in the adapter and thread into tapped holes in the frame endring rigidly secure the adapter to the frame, while bolts that pass through the adapter and thread into tapped holes in the flywheel housing rigidly mount the generator frame and stator to the engine.

Terminal Box

KAMAG generators include a large terminal box with ample room inside for the voltage regulator, most circuit breakers, and other options. The twelve generator stator lead wires and the exciter field leads terminate within the terminal box. The terminal box mounts on the outboard end of the generator.

SECTION 2
RECEIVING INSPECTION, HANDLING INSTRUCTIONS AND STORAGE

RECEIVING YOUR KAMAG GENERATOR

Upon receipt of the generator it is recommended that it be carefully examined to determine if any shipping damage has occurred before accepting the shipment from the transportation company

Generators received during freezing weather should be slowly warmed to prevent condensation of moisture on the windings.

WINDING INSPECTION

Winding inspection prior to operating the generator is recommended. If moisture is observed or condensation of moisture on the windings is suspected, a test of the stator winding insulation resistance should be made. If the result is less than the minimum value, the generator should be dried out.

Insulation resistance of the stator winding in the KAMAG generator should not be less than 1.48 megohms when calculated by the formula that follows.

$$\text{Minimum Winding Insulation Resistance in Megohms} = \frac{\text{Rated Voltage of Generator}}{1000} + 1$$

UNPACKING

Unpack the generator carefully. Make certain that foreign material such as crating nails and packing material does not enter the generator. Read all instruction cards and keep all instructions, drawings, and test cards with the generator as this information will be required by personnel when installing, operating, and servicing the equipment.

HANDLING INSTRUCTIONS

When installed, single bearing generator rotors are supported on the drive end by the drive disks bolted to the engine flywheel. While the engine is removed, the generator rotor must be supported by an appropriate fixture to prevent rotor, stator, or exciter damage.

KAMAG generators are shipped from the factory with rotor shipping support blocking bolted across the drive disks and adapter. Before transporting any generator, the main rotor must be supported by the adapter using an appropriate fixture.

After unpacking the generator, remove the exciter rotor. Leave the exciter rotor removed while transporting and coupling the generator to the engine.

CAUTION

Do not attempt to lift or transport any single bearing generator without proper rotor support. Failure to observe this precaution can result in extensive equipment damage. Make certain exciter rotor is removed while handling generator.

When lifting your KAMAG generator, attach an overhead crane to the lifting eye(s) located on the generator frame. Apply lifting force in a vertical direction if possible. Make certain that crane, lifting cables, and other hardware used is of sufficient strength to safely lift the weight of the generator. Generator weight may be determined by referring to the weight given on the shipment bill of lading.

WARNING

Do not lift complete generator set by means of lifting eye(s) on generator. Disregarding these instructions may result in serious injury or equipment damage.

WARNING

Do not apply any lifting force to generator fan for lifting or turning generator rotor. Failure to observe this instruction may result in serious injury or equipment damage.

STORAGE

When the generator will not be installed on the engine immediately it is recommended that it be stored in a clean, dry area which is not subject to rapid changes in temperature and humidity.

When storage will be for a period of six months or longer it is recommended the unit be wrapped with a thin water proof protective covering, and that a moisture absorbing agent such as bags of silica jel be placed within the covering.

SECTION 3
COUPLING AND ALIGNING GENERATOR AND PRIME MOVER

GENERAL

Flexible steel drive disks mount the generator to the engine flywheel while the face on the generator adapter mounts to the face on the flywheel housing.

Access to the interior of the generator is attained by removing the sheet metal cover that surrounds the stator. Access to the components mounted within the terminal box, such as the exciter and voltage regulator, is attained by removing the terminal box covers.

The generator rotor must be supported by appropriate blocking and the exciter rotor should be removed from the generator shaft while transporting the generator and coupling the generator to the prime mover. In case rotor support blocking has been placed in the generator air gap, be sure to remove support blocking after the bolts that mount the drive disks to the flywheel and the bolts that mount the adapter to the flywheel housing have been started. Install the exciter rotor after drive plate and adapter bolts have been tightened. Refer to the unpacking and handling instructions contained in Section 2 in this manual. Follow the procedure given in Section 9 when removing and installing the exciter rotor assembly.

The generator fan is made in two sections. Bolts hold the sections together and in place on the generator shaft. The fan can be taken apart in order to provide additional space while installing the bolts that mount the drive plates to the flywheel. Before removing or loosening the fan be sure to measure distance fan is located on the shaft from the generator field windings and the drive disks. Be sure to locate fan this distance on the shaft and be sure to tighten and torque fan bolts before operating the generator set. Do not pry on the fan blades. Refer to the handling instructions contained in Section 2 in this manual.

The top rib on the generator frame contains tapped holes for a lifting eye. The lifting eye provides a means for handling the generator. Do not lift complete generator set comprised of "coupled" engine and generator by the generator lifting eye(s). Refer to the handling instructions contained in Section 2.

PRE-COUPLING MEASUREMENTS

It is recommended the measurements that follow be made before coupling the generator to the prime mover.

A. Engine Crankshaft and Flywheel Deflection

Two methods often specified for measuring angular loading of coupled engine driven generator sets are a measurement of crankshaft deflection and flywheel deflection. Where specified by the engine manufacturer, deflection may be specified either as a maximum allowable deflection or as the difference between a measurement taken before the prime mover and generator are coupled and a measurement taken after the units are completely coupled. Where the latter is specified, be sure to make initial measurement before starting to couple the generator to the prime mover. Measure according to engine manufacturer's instructions.

B. Measuring Generator Drive Plate and Flywheel Driving Ring Pilot Bore

The generator drive plates fit into the flywheel driving ring pilot bore. To ensure correct fit, measure as follows.

1. Measure flywheel driving ring pilot bore diameter (dimension B, Figure 5). Compare measured diameter with dimension and tolerance given by flywheel manufacturer as shown in Table 3.
2. Measure generator drive plate diameter (dimension S, Figure 6). Drive plate diameter must not be greater than the flywheel driving ring pilot bore diameter.
3. Measure flywheel driving ring bore face runout. Compare measured runout with maximum tolerance specified by flywheel manufacturer.
4. Measure flywheel driving ring bore eccentricity. Compare measured eccentricity with maximum allowable eccentricity specified by flywheel manufacturer.
5. Measure eccentricity between the driving ring pilot bore B and pilot bearing bore L (see Figure 5). Compare eccentricity measured with maximum eccentricity specified by flywheel manufacturer.
6. Measure depth from flywheel housing face to the flywheel driving ring pilot bore face (dimension G, Figure 5). Compare measured depth G with dimension specified by flywheel manufacturer.

Katolight Service - Master Repair Manual - Page 587

7. Compare measured depth from flywheel housing face to flywheel driving ring pilot bore face (dimension G, Figure 5) with the depth from the generator drive plates to the generator adapter (dimension Y, Figure 6).

NOTE: Where dimensions G and Y are not identical, the circular spacer located between the generator drive hub and the drive plate may be removed or another spacer may be added. Before making any change be sure exciter is axially aligned and bearing has at least 1/8 inch endclearance. Excessive bearing endclearance may prevent bearing outer race from being fully seated in the bearing housing portion of the endbell.

C. Checking Exciter Alignment

Excessive axial misalignment of the exciter armature core and the exciter field can result in low generator excitation and excessive exciter field current. Alignment can be visually checked as given in the procedure that follows.

CAUTION

Do not pull or push on rotating rectifier or winding. Failure to observe this precaution can result in equipment damage.

1. Temporarily slide the exciter rotor (comprised of the exciter armature and rotating rectifier) onto the generator shaft. Make certain inside edge of the exciter armature core is against the raised step on the shaft.
2. Visually check axial alignment.
3. Remove exciter rotor. Install after generator has been coupled to the engine.

D. Checking Bearing Endclearance

Insufficient bearing endclearance can result in thrust load on bearing which will shorten bearing life. Before coupling generator to the engine check bearing endclearance. Refer to the procedure that follows.

1. Make certain generator rotor is axially aligned. Refer to preceding directions.
2. Wrap sling around generator drive hub and attach sling to hoist or place portable jack under drive hub. Take up slack but do not lift. Watch to make certain generator air gap is maintained.
3. Temporarily remove support block from drive end of the generator.
4. With exciter rotor removed, measure from end of the shaft to the bearing housing surface on endbell (dimension A, Figure 4).
5. Push on drive end of the generator rotor until rotor stops moving. This is zero bearing endclearance.
6. Again measure from end of the shaft to the bearing housing and compare this measurement with dimension A measured during step 4. The difference should not be less than 1/8 inch.
7. Remove cover from around generator and visually check to make certain bearing outer race is completely into the bearing housing section in the endbell.
8. Where measurement and checks made in preceding steps 6 and 7 are satisfactory, pull rotor back to the original position measured during preceding step 4.

NOTE: In case bearing endclearance is less than 1/8 inch or bearing outer race is not into the bearing housing, set for 1/8 inch bearing end-clearance, recheck exciter alignment, and then add or remove spacer as necessary from drive end of the generator to attain the correct Y dimension.

COUPLING AND MOUNTING GENERATOR ONTO ENGINE AND BASE

Couple the generator to the prime mover and mount the generator in accordance with the instructions provided by the engine generator set assembler.

The instructions that follow and those contained in preceding sections in this manual are included to facilitate correct coupling of the generator set and to help prevent equipment damage. Review preceding instructions before beginning the following procedure. It is recommended the "Pre-Coupling Measurements" be made before lifting the generator onto the generator set base (see page 3-1).

Katolight Service - Master Repair Manual - Page 588

CAUTION

The exciter air gap is small compared to the air gap within the main generator. Remove exciter rotor before transporting and coupling the generator to the prime mover. Failure to observe this precaution can result in equipment failure.

1. Lift generator onto base with overhead crane. Leave rotor support in place while lifting the generator.
2. Support drive end of generator shaft by wrapping a cable around the drive hub and attaching the cable ends to an overhead hoist or use jack under drive hub. Position jack base on either the generator adapter or the cross member on generator set base.

NOTE: Where generator has removable screen and cover around the adapter, those items may be removed to attain access for cable.

3. Remove wooden support block from face of drive plates and adapter and, where provided, remove support blocking from generator air gap. Be sure to maintain exciter and generator air gap.

NOTE: Step 4 that follows is necessary only where sufficient room does not exist for installing bolts that mount the drive plates to the flywheel.

4. Measure and record axial distance from fan to drive plates. Then loosen or remove fan. When installing fan be sure to position the fan according to this dimension.

WARNING

Do not lift or pry on generator fan. Failure to observe this precaution can result in serious injury and equipment damage.

Be sure to maintain air gap while following steps 5 through 9 that follow.

5. Attach drive plates to the flywheel. SAE Grade 8 bolts are recommended. Make certain plates fit completely into the driving disk recess bore in the flywheel. Move generator stator as necessary to maintain axial alignment of the generator rotor within the stator.
6. Remove sling and hoist from drive hub. Then torque coupling bolts (see Table 2 and Figure 7).
7. Use overhead hoist or jack to align adapter face with the flywheel housing. Check to make certain that faces are parallel using feeler gauge. Install and torque bolts (see Table 2 and Figure 7).
8. Level generator base with the generator set base. Use shims, when necessary.
9. Remove hoist from generator lifting eye(s).
10. Install and torque bolts that mount the generator to the base (see Table 2).

WARNING

Make certain that sufficient clearance exists between fan and stationary parts and make certain fan and fan hub bolts are torqued. Failure to observe this precaution can result in serious injury and equipment damage.

11. Install generator fan and torque fan bolts. See preceding step 4. Torque SAE 5 bolts according to torque listed in Table 2.
12. Check to make certain support blocking and other loose material is removed from air gap.
13. Measure distance from end of generator shaft to the bearing housing portion on endbell (dimension A, Figure 4). Compare measurement with that taken in steps 4 and 6 of preceding procedure titled "Checking Bearing Clearance."

CAUTION

Do not push on rotating rectifier or exciter winding. Failure to observe this precaution can result in equipment damage.

Install exciter rotor as described in steps 14 through 16 that follow.

14. Install key in keyway located in generator shaft. Align exciter rotor with key and push exciter rotor onto generator shaft. Make certain inside edge of exciter armature core is against raised step on shaft.
15. Connect generator field leads onto the (+) and (-) terminals located on the rotating rectifier heat sinks.
16. Install exciter rotor retaining bolt and washer. Torque 1/2 inch bolt to 60 foot-pounds.
17. Check exciter axial alignment.
18. Measure exciter air gap with feeler gauge as described in step19that follows. Air gap at tightest point should not be less than that listed in Table 4.
19. Measure completely around exciter air gap to determine tightest point. Then, keeping gauge at this point, bar engine or flywheel through one revolution, measuring air gap as rotor turns. DO NOT PRY ON GENERATOR FAN.
20. When specified by the engine manufacturer, test flywheel deflection or crankshaft deflection.
21. Measure generator rotor eccentricity as described in the procedure that follows.
22. Measure generator rotor angular alignment as described in the procedure that follows.
23. After coupling and mounting is complete and measurements are satisfactory, inspect to make certain all bolts are tight and torqued (see Table 2).

WARNING

When circuit breakers are not included with the generator, the terminals on the ends of the stator lead wires are not insulated. These terminals must be insulated before generator set is operated. Failure to observe this precaution can result in serious injury and equipment damage.

24. Bar engine or flywheel through at least one revolution, checking to make certain that clearance exists between stationary and rotating parts. DO NOT PRY ON GENERATOR FAN.
25. Check to make certain that tools and shop cloths are removed from in and around generator set. Make certain that wiring is connected and lugged ends are insulated. Then install generator covers.
26. Disconnect engine starting circuit; then operate engine through cranking cycle. Listen for any abnormal rubbing or scraping noises.

MEASURING GENERATOR ROTOR ECCENTRICITY

After the generator has been coupled to the prime mover, a measurement of generator rotor eccentricity should be made to ensure generator rotor shaft has been aligned with the engine. Do not pry on generator fan. Measure eccentricity and, where necessary, correct alignment as follows.

1. Mount dial indicator base on the generator adapter and position the dial indicator finger on the generator drive hub or generator shaft as shown on Figure 8.
2. Set dial indicator needle to zero.
3. Bar engine or flywheel one revolution. Do not pry on generator fan.
4. Eccentricity should not exceed .003 inch total indicator reading on 1500 rpm to 1800 rpm generator sets.
5. In the event eccentricity exceeds the maximum tolerance given above, align coupling as given in procedure 6 or 7 that follows.
6. Attach hoist and cable about drive coupling to support drive end of generator rotor or use jack under drive hub with jack base on adapter rib or base cross member. Loosen bolts that mount the drive plates to the flywheel. Then move drive plates in the direction within the flywheel driving ring recess bore that will decrease eccentricity. Remove cable hoist, torque bolts, and again measure eccentricity.
7. To decrease eccentricity it may be necessary to rotate the drive plates with respect to the flywheel driving ring pilot bore. Support the drive end on the generator rotor with a cable and hoist or jack. Remove coupling bolts and turn the flywheel. Be sure to keep the generator drive plates stationary. Rotate the flywheel to position where eccentricity will be minimum and bolt holes are aligned. The install and torque bolts, remove cable and hoist, and again measure eccentricity.

MEASURING ROTOR ANGULAR ALIGNMENT

After the generator has been coupled to the prime mover, a measurement of angular alignment of the generator rotor with the engine flywheel should be made. Measure angular alignment and, where necessary, correct as follows.

1. Measure approximate distance between shaft center and any convenient point on the flywheel slightly larger than the driving ring pilot bore. This dimension is used in the procedure described in steps 2 and 6 that follow.
2. Mount dial indicator base on the generator fan and position the dial indicator finger on the flywheel according to dimension measured in step 1 and as shown on Figure 9.
3. Set dial indicator to zero.
4. Do not pry on generator fan.
5. Bar engine or flywheel through one revolution while measuring angular runout.
6. Angular runout must not exceed ± .010 inch per foot of radius measured from shaft center to indicator finger. Where radius used during measurement is other than one foot, calculate according to dimension from preceding step 1.
7. In the event excessive angular runout occurs, inspect and measure or verify the previous measurements as necessary to ensure the items that follow were installed correctly and tolerances are within the specified limits.
   a. Make certain that drive plates are seated in the flywheel driving ring pilot bore and coupling bolts are torqued (see Table 2 and Figure 7).
   b. Verify that adapter face and flywheel housing face are aligned and bolts are torqued (see Table 2 and Figure 7).
   c. Verify that while mounting the generator to the base an angular load was not applied causing flywheel housing deflection. Check may be made by loosening mounting bolts and moving generator stator slightly with hoist or jack screws while measuring angular alignment.

NOTE: For some engine generator combinations, the flywheel housing may have to be supported by feet to attain angular alignment.

   d. Verify that flywheel deflection and crankshaft deflection are not excessive.
   e. Verify that the generator driving plate bore is concentric with the driving plate pilot on the generator drive hub.
   f. Verify that the flywheel housing face runout does not exceed specified tolerance.
   g. Verify that flywheel driving ring pilot bore face runout does not exceed specified tolerance
   h. Verify that the eccentricity between the flywheel pilot bore (L) and the driving ring pilot bore (B) does not exceed specified tolerance

SECTION 4
ELECTRICAL CONNECTIONS

GENERAL

KAMAG generators have twelve stator lead wires that terminate within the terminal box. The two lead wires from the exciter field winding also terminate within the terminal box.

The generator may be connected three-phase series wye, three-phase parallel wye, three-phase series delta, three-phase parallel delta or single phase. The units may be operated 60 Hertz, 1800 rpm or 50 Hertz, 1500 rpm. The voltage regulating system voltage control rheostat permits adjustment of generator output voltage.

Voltage generated when stator lead wires are connected in one of the configurations described above is listed in Table 1. Select the hookup that will provide the appropriate voltage. Be sure to connect the generator stator, load lines and voltage regulator as shown in the wiring diagram provided with the generator. Observe the general precautions that follow.

A. Three-Phase Wye Connected Generator

For a 4-wire system the neutral line may be brought out to the load distribution system. Where electrical code requires system ground, be sure the neutral leg is electrically connected to ground stud or ground wire.

B. Three-Phase Delta Connected Generator

Where generator is connected 3-wire delta, the stator connection neutral should not be connected to the ground stud and load lines do not contain a neutral line. The load conductors (phase A, B, and C) should not be grounded.

C. Single Phase Three Wire

Neutral (N) and two load conductors (L1 and L2) are contained in the load distribution system. Where electrical code requires system ground, neutral leg may be grounded.

D. Single Phase Two Wire

Two load conductors connect to the load distribution system. In single phase two wire 200-240 VAC applications where generator neutral is grounded, the two load conductors must not be grounded.

E. Generator Frame Ground

Generator frame should be connected to an earth ground in accordance with electrical code. Ground wire must be connected to the generator ground stud located above the left mounting foot.

F. Exciter Field Lead Wires

Exciter field lead wires F+ and F- connect to the voltage regulator output terminals F+ and F-. Be sure to maintain polarity. THIS CIRCUIT MUST NOT BE EITHER GROUNDED OR OPENED WHILE GENERATOR IS RUNNING.

G. Voltage Regulator

Refer to the voltage regulator instruction manual and the wiring diagram provided with the generator set. Make certain all internal and external connections are correct before operating the generator set.

CAUTION

Incorrect electrical connection of the voltage regulator can result in immediate equipment damage.

H. Voltage Regulator Fuse

This fuse protects the voltage regulator circuitry.

In applications where the generator set does not include a field circuit breaker it is recommended that a 1 1/2 ampere normal blow fuse be used in the voltage regulator. This would protect the Kamag generator against excessive voltage due to loss of sensing and excessive field forcing.

I. Voltage Regulator System Equipped with Paralleling Components

Refer to the voltage regulator instruction manual, the wiring diagram provided with the generator set, and the parallel operation instructions contained in Section 5 in this manual.

Where generators will be operated parallel, the voltage regulating system must include additional paralleling provisions either internally or external to the regulator and each regulating system must include a parallel operation current transformer.

Katolight Service - Master Repair Manual - Page 592

The parallel operation components may be connected by either of the two methods that follow.

1. **Reactive Voltage Droop Compensation (Formerly known as parallel droop compensation)**
   To attain reactive voltage droop compensation in parallel equipped voltage regulators, the generator set parallel operation current transformer connects to its respective voltage regulator. When connected in this manner the bus voltage droops, or decreases, as the reactive lagging power factor load is applied. Where this method is required, connect the current transformers as described in the voltage regulator instruction manual and generator set wiring diagram.
2. **Reactive Differential Compensation (Formerly known as cross-current compensation)**
   To attain cross current compensation in parallel equipped voltage regulators, the parallel current transformers are interconnected and also connect to their respective voltage regulators. Reactive differential compensation permits reactive load sharing without a droop, or decrease, in generator voltage. Where this method is required, connect the current transformers as described in the voltage regulator instruction manual and generator set wiring diagram.

J. Voltage Shutdown Switch (Engine Idle Switch)
Where this accessory is provided, connect as described in the voltage regulator instruction manual and generator set wiring diagram.

K. Field Circuit Breaker
Where this accessory is provided, connect as described in the voltage regulator instruction manual and the generator set wiring diagram.

L. Automatic/Manual Voltage Control
Where this accessory is provided, connect as described in the voltage regulator instruction manual and the generator set wiring diagram.

M. Space Heaters
Where this accessory is provided, connect as described on the generator set wiring diagram.

SECTION 5
OPERATION

PRE-START INSPECTION

Before operating the generator for the first time, the following checks are recommended.

WARNING

When circuit breakers are not included with the generator, the terminals on the ends of the stator lead wires are not insulated. These terminals must be insulated before generator set is operated. Failure to observe this precaution can result in serious injury and equipment damage.

A. Check to make sure bolts that mount and couple the generator onto the engine and engine base are tight.
B. Check to make sure fan bolts are tight and space exists between the fan and stator windings. Check to make sure exciter retaining bolt is tight.
C. Check all wiring against the proper connection diagrams and make sure all connections are properly insulated.
D. Inspect to make sure all packing materials and shipping support blocking has been removed. Remove loose cloths and tools.
E. Install covers and guards.

IDLING

Permanent equipment damage can be caused by having the generator set in operating mode while idling the engine. If engine adjustments require that the engine be run at idle speed, the generator set regulating system should be made inoperative by one of the methods that follow.

A. Where generator set is provided with voltage shutdown switch, be sure switch is set to IDLE position while engine is running at idle speed.
B. Where generator set is equipped with field circuit breakers, be sure the circuit breaker is set to OFF while engine is running at idle speed.
C. Where generator set includes an automatic/manual control with switch that has OFF position, be sure switch is set to OFF while engine is running at idle speed.
D. Where generator set does not include switches described above, be sure voltage regulator fuse is removed while engine is running at idle speed or remove wires from the voltage regulator input power terminals during underspeed operation of the generator set.

FIELD FLASHING

The generator relies on residual voltage to start the generator action which in turn generates the rated voltage. If the generator fails to generate voltage after it has come up to rated speed, it may be necessary to flash the exciter field. Field flashing must be done while the generator is at a standstill as described in the procedure that follows.

1. Stop the engine and open the output circuit breaker.

CAUTION

Be sure to maintain polarity (+) to (F+) and (-) to (F-).

2. Connect the negative lead (-) from a common 12 volt storage battery onto exciter field lead F-.
3. Connect the positive lead (+) from the battery onto exciter field lead F+. Only a few seconds flashing should be necessary.
4. Remove battery and connect exciter field leads onto voltage regulator terminals F+ and F-. Be sure to maintain correct polarity.
5. Start generator and check for satisfactory voltage build up.

VOLTAGE ADJUSTMENTS

A means for adjusting the voltage is incorporated in the regulator. For details refer to the voltage regulator instruction manual applicable for this unit.

VOLTAGE RANGE ADJUST

This control is incorporated in most voltage regulators. For details refer to the voltage regulator instruction manual applicable for this unit.

STABILITY ADJUSTMENT

This control is incorporated in most voltage regulators. It provides a means of adjusting a stabilizing signal which prevents generator voltage oscillation. For details refer to the voltage regulator instruction manual applicable for this unit.

STARTING UP THE GENERATOR FOR SINGLE UNIT OPERATION

The following procedures should be followed for starting up the generator set.

1. The generator output must be disconnected from the load. Be sure the main circuit breaker is open.
2. If fuses have been removed, install the fuses.
3. Where generator set is equipped with field circuit breaker, set breaker to ON.
4. Where generator set is equipped with voltage shutdown switch, set switch to RUN position.
5. Where generator set is equipped with Automatic/Manual control, set switch to AUTO position.
6. Where space heaters have been supplied with the generator set, turn off the heater before operating the generator.
7. Where generator sets are equipped for parallel operation and include UNIT/PARALLEL switches, set switch to UNIT position whenever generator is operated singly.
8. Start generator set and bring to rated speed. Adjust voltage to required value by means of the voltage adjust rheostat.
9. Close the main circuit breaker and apply load.
10. Adjust engine speed to 1800 rpm for 60 Hertz, 1500 rpm for 50 Hertz.
11. Before stopping the engine, remove the load by tripping the main circuit breaker.

PARALLEL OPERATION

KAMAG generators come standard with amortisseur windings. This feature makes all KAMAG generators suitable for parallel operation when the proper control equipment is added.

Generators operating parallel must deliver power to the load without delivering power to each other or accepting power from the load bus or power grid.

Additional equipment is necessary to ensure safe and successful parallel operation. The amount of control gear will be determined by the needs and requirements for the particular application. A description of the minimum control equipment necessary for parallel operation follows.

A. Prime Mover Governor

The prime mover speed will directly control the kilowatt load and frequency of the unit. The governor must have special paralleling and droop provisions to permit parallel operation with other units.

B. Voltage Regulator Paralleling Provisions

The voltage regulator controls the generator output voltage and the reactive power supplied by the generator. Where two or more generators operate parallel, the voltage regulators must have a similar characteristic, and each regulator must include paralleling provisions either internally or external to the regulator. These include an external current transformer for each regulating system, a voltage droop adjustment for each regulating system, and paralleling transformer or equivalent circuitry internally or external to the regulator. Where parallel systems are interconnected for reactive differential compensation, each regulating system should include either a UNIT/PARALLEL switch or auxiliary contact on the generator circuit breaker.

C. Synchroscope or Synchronizing Lights

Where generator is being paralleled with another generator supplying power to the system bus, the voltage of the incoming unit must be in phase with that of the load bus at the instant its circuit breaker closes.

Attempting to parallel units while out-of-phase voltage condition exists will result in very high transient voltage and mechanical strain which can result in extensive equipment damage.

A synchroscope or synchronizing lights provide means of determining when generator is inphase with the bus voltage.

D. Metering

In order to check for proper parallel operation, all generators should be equipped with the following monitoring equipment.

Synchroscope or Synchronizing Lights
AC Voltmeter
AC Ammeter
Frequency Meter
kW Meter
kVAR or Power Factor Meter

Automatic/Manual Control During Parallel Operation

Where one or more of parallel operation generator sets are equipped with automatic/manual control circuitry, all generators must be operated in the automatic voltage control mode during parallel operation. This is accomplished by setting the automatic/manual control selector switch to AUTO position.

Phase Rotation

For parallel operation each generator must have the same phase rotation with respect to the load bus. Each generator should be checked to ensure correct phase rotation before parallel operation is attempted.

Pre-paralleling Adjustments and Checks

Before operating generator sets parallel, each set should be checked by starting, operating, and adjusting the sets as individual units before paralleling.

The following points are basic criteria which must be met before two units can be paralleled.

A. The generators must have the same phase rotation. Test by using phase rotation meter or checking rotation of induction motor connected to load bus.

B. The voltage regulator characteristics of the individual generators should be similiar and must include parallel operation circuitry.

C. Paralleling current transformers must give the same secondary current.

D. Current transformer secondary winding provides reactive kVA droop signal to the voltage regulator. Accidental reversal of this electrical wiring will cause voltage to rise rather than droop. If this occurs, stop unit and reverse wires at voltage regulator terminals CT1 and CT2.

E. Each set must be individually adjusted for identical voltage droop. Individually test and adjust with an inductive load applied that is proportional to full load rating of unit.

F. Where generator sets include UNIT/PARALLEL switch, set switch to PARALLEL position on units being brought on the load bus.

G. The engines must have the same speed regulating characteristics, and the governors must be adjusted to give the same speed regulation. Individually test and adjust with load applied that is proportional to full load rating of generator.

H. Each engine governor must be adjusted for identical speed droop. Individually test and adjust by applying load that is proportional to full load rating of the generator.

Paralleling

Verify that units are properly equipped for parallel operation and adjustments have been made as described in preceding instructions. General procedure follows.

1. Where generator set includes automatic/manual voltage control, set AUTO/OFF/MANUAL switch on all units to AUTO position.
2. On generating systems equipped with UNIT/PARALLEL switches, set switch on unit being started (generator set No.1) to PARALLEL position (open). Set switch on remaining generator sets to UNIT position (closed).
3. Start generator set No. 1.
4. Adjust generator voltage and engine speed.
5. Apply the load.
6. Verify satisfactory voltage regulation and make certain frequency is not fluctuating.
7. Repeat procedures 1 and 2 on generator set No. 2.
8. Start generator set No. 2.

9. Adjust generator set No. 2 speed and voltage.
10. Adjust speed of generator set No. 2 slightly higher than that of generator No. 1.
11. Observe the synchroscope (or lights). When generator No. 2 is inphase with generator No. 1, close the circuit breaker for generator No. 2.
12. Immediately after closing the circuit breaker, measure line current of generator No. 2. It should be well within the rating of the generator. Also, immediately after closing the circuit breaker, observe the kW or power factor meters. The following conditions could occur.
    a. **A high ammeter reading accompanied by a large kW unbalance.** When this condition exists, the speed governor is either not adjusted correctly or is faulty.
    b. **A high ammeter reading accompanied by a large kVAR unbalance.** When this condition exists, the voltage regulating system is either not adjusted correctly or is faulty.
13. Adjust the speed of generator set No. 2 to the rpm where each generator is carrying the desired share of kW load. (See Note following procedure 14).
14. Adjust the voltage of generator No. 2 until the ammeter readings of both generators are near minimum. (See following Note).

NOTE: If kVAR or power factor meters are available, adjust voltage adjust rheostats for equal or proportional kVAR or power factor readings.

If the generators are equipped with power factor meters, alternately adjust the speed and voltage on No. 2 until the ammeter readings are proportional and the power factor readings are equal.

NOTE: To obtain best results, final adjustments should be made with full load on the bus.

15. With full load applied, readjust the speed and voltage of generator No. 2 until the desired load division is obtained.

NOTE: The best adjustment is obtained when each generator supplies the same percent of its rated current, the power factor readings are equal, or the sum of the ammeter currents is minimum.

16. In applications where three or more generators are to be operated parallel, repeat procedures 7 through 15 for generator set No. 3, then No. 4, etc.

Shutting Down One or More Generators Operating Parallel

Before dropping one or more generators operating parallel from the line bus it is essential that the total load on the bus is reduced to equal to or less than the combined capacity of the generators remaining on the bus. Shut down one or more of generator sets operating parallel as follows.

1. Reduce load to combined capacity of generators remaining on the bus.
2. On systems where the prime mover governor is equipped with a manual speed adjust, the load can be shifted to generators remaining on the bus by reducing the speed of the generator set being dropped from the bus.
3. Open the circuit breaker on the generator set being taken off the bus.
4. Close its UNIT/PARALLEL switch (on generator sets equipped with a UNIT/PARALLEL switch).
5. Shut down the prime mover.
6. In applications where three or more generators are operated parallel, repeat preceding procedures 1 through 5 for each generator set being taken off the bus.

SECTION 6
PREVENTIVE MAINTENANCE

INSPECTION

To ensure peak performance and maximum service life, the generator must be kept in good condition. This can best be ensured by periodic inspection of the unit and immediate repair of minor problems. The preventive maintenance inspection schedule that follows is enclosed as a guide for establishing a preventive maintenance program.

A. Daily or Whenever Generator is Operated

Before starting generator be sure air inlet and air exhaust screens are not clogged.

While generator is running be sure voltage is correct and not oscillating.

While generator is running observe any unusual noise or vibration.

B. Once Every Six Months

Remove terminal box cover and inspect wiring for signs of damaged insulation and loose or corroded connections. Repair damaged wiring; clean and tighten connections.

Inspect control devices for accumulation of dust, moisture or other foreign material. Clean using nylon bristle brush or compressed air at pressure between 25 PSI and 50 PSI.

Inspect to make certain that bolts which mount the voltage regulator, circuit breakers, meters, etc. have not loosened. Tighten as necessary.

Remove or loosen cover that surrounds generator frame. Inspect inside of generator frame. Inspect inside of generator for signs of damaged winding insulation and excessive dirt or moisture. Inspect to make certain bolts are tight.

CLEANING

A. Controls

Clean using nylon bristle brush or compressed air at pressure between 25 PSI and 50 PSI.

B.Generator

Wipe exterior of generator and air intake and exhaust with cloth or nylon bristle brush. Clean loose dust or other abrasive material from generator interior using compressed air at pressure between 25 PSI and 50 PSI.

SECTION 7
TROUBLESHOOTING

GENERAL

Loose, corroded, or broken connections and wiring errors are often the cause of generator malfunction. Before assuming problem is within the generator or voltage regulator, check condition of wiring and terminal connections and verify wiring according to wiring diagrams provided with the generator set.

TROUBLESHOOTING PROCEDURE

The troubleshooting information that follows is divided by symptoms. They are: no voltage, low voltage, high voltage, and voltage fluctuating.

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

A. No Voltage

1. Shut down the generator set.
2. Remove terminal box cover and check generator leads and interwiring to the voltage regulator for loose or broken connections.
3. Check regulator fuses with ohmmeter. If defective, replace.
4. Start up generator. Measure ac voltage at input power terminals on the voltage regulator. The voltmeter reading should exceed 7 vac. If it does not, field flashing is required. Refer to field flashing procedure in Section 5 of this manual.
5. Where voltage reading before or after field flashing exceeds 7 vac but output voltage fails to build-up, shut down the generator set. Then proceed as described to either step 6 or steps 7 and 8 that follow.
6. Connect meters as shown in Figure 12. Then start generator set and measure exciter field excitation as described in Section 8.
7. Shut down the generator set. Disconnect voltage regulator by removing the voltage regulator fuse. Where regulator does not include fuse, disconnect voltage regulator by removing the connections to the regulator input power terminals. Insulate terminal lugs on wires to prevent grounding during test described in step 8 that follows.
8. Disconnect wires F+ and F- from regulator output terminals F+ and F-. Connect a common 12 volt storage battery to wires F+ and F-, keeping the polarity the same. Start up the generator set. While the generator is operating at a rated speed, read the voltage output of the generator measured by a voltmeter. If the reading is one-half or greater of the rated output when there is no load on the generator, the problem is in the voltage regulator. If the voltage remains near zero, the voltage regulator is good, and the problem is most likely within the exciter or generator. Shut down the generator. Reconnect the voltage regulator and proceed to step 9.
9. Remove cover located on end of terminal box. Examine the rectifier diodes for loose or broken connections. Proceed to step 10.
10. Test the generator exciter rotating rectifier diodes as described in the procedure contained in Section 8. Refer to Figures 3 and 11. Install diodes and reconnect generator field leads.
11. Test surge suppressor as described in Section 8. Surge suppressor is mounted across the positive and negative heat sinks on the exciter rectifier. If test shows replacement is necessary, see installation instructions in Section 9. Part location and electrical connections are shown on Figures 3 and 11. Reconnect generator field leads. If test indicates surge suppressor is good, proceed to step 12.
12. Check windings for continuity as described in the winding resistance test procedure contained in Section 8. If opens or shorts are found in the exciter stator or exciter armature, replace the necessary component. If the condition is found in the generator stator or the generator rotor field winding, major repair or generator replacement is probably required.
13. Connect wiring in accordance with wiring diagram(s) provided with the generator set.

Katolight Service - Master Repair Manual - Page 599

B. Low Voltage

1. Test using auxiliary voltmeter connected at generator load leads.
2. Shut down the generator set.
3. Remove cover located at end of terminal box. Check main generator leads and wiring to the voltage regulator for correct connection. Make certain that connections are tight and not corroded.
4. Start up the generator set. Verify correct speed (1800 rpm for 60 hertz and 1500 rpm for 50 hertz).
5. Be sure the voltage adjust rheostat is adjusted as necessary to increase generator voltage.
6. Adjust the voltage range potentiometer clockwise to increase generator voltage.
7. Where voltage is normal with no-load applied but drops with load applied, make certain load does not exceed nameplate capacity. Verify using clamp-on ammeter on the generator load lines. Current in any line must not exceed nameplate amps.
8. Shut down the generator set and open the output circuit breaker.
9. Check wiring to the voltage regulator sensing and input power terminals. Where voltage regulator has multi-tap sensing transformer, make certain connections to the transformer are correct. Where voltage regulator has different internal connections for 60 Hertz and 50 Hertz operation, verify connections are correct. Where voltage regulator is of the series boost saturable transformer type, verify that boost winding is connected correctly. Refer to the voltage regulator instructions and the wiring diagrams provided with the generator set. Where connections are found to be correct, proceed as follows.
10. Continue by testing either field excitation as described in step 11 or test using battery as described in steps 12 through 14.
11. Connect meters as shown in Figure 12. Then start generator set and measure exciter field excitation as described in Section 8.
12. Disconnect the voltage regulator by removing wires at the regulator input power terminals and the regulator output terminals F+ and F-. Tape ends of input power wires to prevent accidental ground or short during the test described in step 11.
13. Connect a common 12 volt storage battery to exciter field lead wires F+ and F-, keeping the polarity the same. Start up the generator set. While the generator is running at rated speed, read the voltage output. If the reading is one-half or greater when there is no-load on the generator, the problem is in the voltage regulator. If the reading remains near zero, the problem is most likely within the exciter or generator.
14. Shut down the generator set. Remove battery and reconnect voltage regulator determined to be in good condition. If preceding test indicated that the problem was within the exciter or generator, test as described in the steps that follow.
15. Remove the cover located on end of terminal box. Examine the rotating rectifier diodes for loose or broken connections. If connections are good, proceed to step 16.
16. Test rotating rectifier diodes using an ohmmeter as described in Section 8. If one reading is high and the other is low, the diode is good. A shorted diode will have very low resistance in both forward and reverse polarity while an open circuited diode will exhibit high resistance in both forward and reverse polarity. Install good or replacement diodes. Connect generator field leads.
17. Test surge suppressor as described in Section 8. Install replacement surge suppressor as described in Section 9. Re-connect generator field leads. If test indicates that surge suppressor is good, proceed to step 18.
18. Check windings for continuity as described in the winding resistance test procedures contained in this manual. If opens or shorts are found in the exciter stator or exciter armature, replace the necessary component. If the condition is found in the generator stator or rotor, major repair or generator replacement is probably required.

C. High Voltage

1. Verify by testing with an auxiliary voltmeter at the generator load lines.
2. Be sure the voltage adjust rheostat is adjusted as necessary to reduce voltage.
3. Adjust the voltage range potentiometer in the voltage regulator counter-clockwise to reduce voltage.
4. Shut down the generator set and open the generetor output circuit breaker.
5. Remove terminal box cover and check generator set wiring for correct connection.

6. Check wiring to the voltage regulator sensing and input power terminals for correct connection. Check voltage regulator sensing transformer for correct connection. Where voltage regulator includes different internal connections for 50 Hertz or 60 Hertz, verify that connections are correct. Where voltage regulator is of the type that has boost transformer or winding, verify that connections are correct. Refer to the wiring diagrams provided with the generator set and the voltage regulator instructions.

D. Voltage Fluctuating

1. Verify generator voltmeter performance using auxiliary voltmeter at generator lines.
2. Verify engine governor performance with a tachometer to ensure stable engine speed.
3. Where generator is providing power to SCR type load, transient voltage spikes during SCR switching can cause voltage to fluctuate. If this is the case, set stability adjust for slower regulator response.
4. Adjust voltage regulator stability control potentiometer as described in the voltage regulator instruction manual. Test with no load applied and again with load applied.
5. Shut down generator set and open generator output circuit breaker. Remove the terminal box cover and check all wiring for loose connections.
6. Where wiring is found to be correct and in good condition, proceed to either step 7 or steps 8 and 9.
7. Connect meters as shown on Figure 12 and measure exciter field excitation as described in Section 8.
8. Shut down generator set and remove cover located on end of terminal box. Proceed to step 9.
9. Disconnect the voltage regulator by removing the connections to the regulator input power terminals. Tape lugged ends on wires to prevent ground or short during test. Remove F+ and F- exciter field lead wires from the F+ and F- terminals on the voltage regulators. Connect a common 12 volt storage battery onto exciter field leads F+ and F- keeping the polarity the same. Start up the generator set. While generator is operating at rated speed, read the voltage output on a voltmeter. Following this procedure, if the voltage is one-half or greater of rated output and does not fluctuate when there is no load on the generator, the problem is within the voltage regulator. Consult the voltage regulator instruction manual for further information.

SECTION 8
GENERATOR TESTS

MEASURING EXCITER FIELD EXCITATION

Exciter field excitation can be measured using a dc voltmeter and dc ammeter connected in the circuit between the voltage regulator dc output and exciter field as shown in Figure 12. The meters must be capable of measuring full load excitation. This will vary according to the size of the generator and can be determined from the test card attached to the generator or by contacting Kato Engineering/Reliance Electric, Mankato, Minnesota. Be sure to provide the generator serial number when requesting information.

Procedure

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

1. Connect dc voltmeter and dc ammeter as shown in Figure 12.
2. Start unit and run at rated speed.
3. Measure no-load excitation. The following abnormal conditions could occur.
   a. **Generator Output Voltage Low, with Normal or Higher than Normal Excitation**
      If this condition occurs, the problem is within the generator or exciter. Test the rotating rectifier diodes and winding resistance.
   b. **Generator Voltage Low and Excitation Low**
      If this condition occurs, the problem is within the voltage regulator or the wiring to the voltage regulator.
   c. **No Generator Voltage and No Excitation**
      If this condition occurs, flash exciter field to restore residual magnetism as described in the procedure given in Section 5 in this manual.
4. Measure excitation with full load applied. The following abnormal conditions could occur.
   a. **Generator Voltage Low and Full-Load Excitation Normal or Higher Than Normal**
      If this condition occurs, verify that speed is not low. Make certain load does not exceed rated full load current given on the generator nameplate.
   b. **Generator Voltage Low and Full Load Excitation Low.**
      If this condition occurs, problem is within the voltage regulator.

TESTING EXCITER ROTATING RECTIFIER DIODES

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment. Refer to Figure 13 for test setup.

Stop generator set. Remove cover located on the end of terminal box. Test as described in the procedure that follows using ohmmeter or three-volt test light.

NOTE: Where three-volt test light is used: bulb should light when connected in low resistance circuit and should not light when connected in high resistance circuit.

1. Unsolder wire connected to diode, then remove diode from heat sink (see Figure 3).
2. Measure resistance across diode. Reverse meter probes and again measure resistance.
   A good diode will have low resistance in the normal direction of current flow and high resistance to reverse current. High resistance both forward and reverse indicates diode has become open and should be replaced. Where light is used, failure of bulb to illuminate in both forward and reverse tests indicates an open diode.
   Very low resistance both forward and reverse indicates a shorted diode.
   Where light is used, diode is shorted when light illuminates during both forward and reverse polarity test.
3. Install diode. Torque 15 inch-pounds. Where original diode is replaced, make sure replacement diode is of the same rating and polarity.

4. Solder wire onto diode (see Figures 3 and 11).
5. Repeat steps 1 through 4 until each diode has been tested.

TESTING SURGE SUPPRESSOR

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

Refer to Figure 14 for test setup. Stop generator set. Remove cover located on end of terminal box. Disconnect one lead and check with lamp tester. The lamp should not light when the test leads are placed across the surge suppressor in either direction. If the lamp lights, it indicates a shorted surge suppressor. Replace defective surge suppressor with one of the same specifications as the surge suppressor installed at the factory. Order by part number and include the serial number of the generator.

MEASURING WINDING RESISTANCE

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

Resistance test of winding may be made to determine whether winding has become open circuited. Resistance measured across a winding that has become open circuited will be very high (near infinity). In the case of shorted turns, resistance will generally be lower than normal. Where shorted turns are suspected, additional test using growler is recommended. Short to ground may be determined by testing winding insulation resistance using a hand cranked 500 VDC megger.

Resistance of winding will vary in proportion to the winding temperature. Where winding temperature is either higher or lower than 25°C (77°F), the formula that follows should be used to compute resistance.

$$\text{Resistance at } 25^\circ\text{ C} = \text{Measured Resistance} \times \frac{234.5 + 25}{234.5 + \text{Winding temp. in } ^\circ\text{C}}$$

A. Measuring Exciter Field Winding Resistance

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Remove exciter field leads F+ and F- from the F+ and F- terminals on the voltage regulator.
3. Connect ohmmeter onto exciter field leads F+ and F- and measure exciter field winding resistance.
4. Where winding temperature is either high or lower than 25° C, compute resistance as given in the formula contained in preceding topic "Measuring Winding Resistance."
5. Before starting generator set be sure to connect field leads onto voltage regulator terminals F+ and F-. Maintain correct polarity (F+ to F+ and F- to F-).

B. Measuring Generator Field Winding Resistance

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Remove generator field leads from the exciter rotating rectifier heat sink (+) and (-) terminals.
3. Connect test instrument such as Wheatstone bridge or Kelvin bridge onto generator field leads and measure generator field winding resistance.
4. Where winding temperature is either higher or lower than 25°, compute resistance as given in the formula contained preceding topic "Measuring Winding Resistance."
5. Before starting generator set, be sure to connect generator field leads onto the rotating rectifier heat sinks. Maintain correct polarity (positive to + and negative to -).

C. Measuring Exciter Armature Winding Resistance

This test requires removing the exciter armature lead wires from the exciter rotating rectifier diodes (refer to Figures 2 and 3).

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Observe which of the exciter rotating rectifier diodes each of the three exciter armature leads connect to. Then unsolder any two of the three exciter armature lead wires.
3. Measure exciter armature phase-to-phase resistance using test instrument such as Kelvin bridge connected between exciter armature phase 1 lead wire and phase 2 lead wire. Repeat measuring from phase 1 to 3 and again phase 2 to 3.
4. Phase to phase resistances should be quite similiar. Where winding temperature was either higher or lower than 25° C, compute resistance as given in formula contained in preceding topic "Measuring Winding Resistance."
5. Before starting generator set be sure to solder leads onto the exciter rotating rectifier diodes (refer to Figures 3 and 11).

D. Measuring Generator Stator Winding Resistance

The stator has twelve lead wires brought out from the coil groups permitting connection of the generator stator winding series wye, parallel wye, series delta, parallel delta, or single phase. It is recommended that when testing winding resistance the stator be connected three-phase series wye by connecting the stator leads as shown in Figure 9.

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect the twelve generator stator leads numbered 1 through 12 from outgoing load lines, and the leads to voltage regulator, current transformers, and meters.
3. Connect stator leads in series wye configuration as shown in Figure 10 (a).
4. Measure resistance Phase 1 to 2 using a Kelvin bridge. Then measure Phase 1 to 3 and Phase 2 to 3. Phase to phase resistances should be quite similiar. Where winding temperature was either higher or lower than 25° C, compute resistance as given in formula contained in preceding topic titled "Measuring Winding Resistance."
5. Connect generator wiring as shown on the wiring diagram provided with the generator set.

MEASURING WINDING INSULATION RESISTANCE

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

The insulation resistance will slowly decrease over the normal life of the generator. Test will indicate abnormal decrease in insulation resistance. Where insulation resistance test is to be made, use a 500 VDC hand cranked megger.

A. Measuring Generator Stator Winding Insulation Resistance

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect wiring from the twelve generator stator lead wires.
3. Connect stator leads in series wye configuration as shown on Figure 10 (a). Be sure to remove neutral lead from ground connection.
4. Connect megger gound lead to generator frame.
5. Connect megger lead onto phase 1 stator lead wire number 1. Make certain no connections other than the megger ground lead are touching the generator frame or other metal parts.
6. Test stator winding insulation resistance. Resistance should not be less than 1.48 megohm. If insulation resistance is lower than minimum value given above, determine cause of low insulation resistance. If due to wet windings, dry out the generator as described in Section 9 in this manual.

7. Before operating generator, connect wiring as shown on the wiring diagram supplied with the generator set. Install covers.

B. Measuring Generator Field Winding Insulation Resistance

Use 500 VDC, hand cranked megger.

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect the generator field leads from the (+) and (-) terminals located on the exciter rotating rectifier assembly heat sinks.
3. Connect megger ground lead onto either the generator shaft, fan, or drive hub.
4. Connect megger test lead onto either of the generator field lead wires. Make certain non-insulated lugs on field leads are not touching any generator parts.
5. Measure generator field winding insulation resistance. If the generator field winding insulation resistance is less than one megohm, determine cause of abnormally low insulation resistance. If due to wet windings, dry out generator as described in Section 9 in this manual.
6. Before operating the generator set, connect generator field leads onto exciter rotating rectifier heat sink (+) and (-) terminals (See Figure 3). Install covers.

C. Measuring Exciter Field Winding Insulation Resistance

Test using 500 VDC hand cranked megger as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect exciter field leads F+ and F- from the voltage regulator terminals F+ and F-.
3. Connect megger ground lead to the generator frame.
4. Connect megger test lead onto either exciter field lead F+ or exciter field lead F-. Make certain non insulated ends on leads F- and F+ do not touch any metal parts.
5. Measure exciter field winding insulation resistance. If insulation resistance is less than one megohm, determine cause of abnormally low insulation resistance. If due to wet winding, dry out generator as described in Section 9 in this manual.
6. Before operating generator set, connect F+ lead wire onto voltage regulator terminal F+ and lead wire F-onto voltage regulator terminal F-. Install covers.

D. Measuring Exciter Armature Winding Insulation Resistance

Test using 500 VDC megger as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Using soldering gun, disconnect the three exciter armature lead wires from the exciter rotating rectifier assembly (see Figures 3 and 11).
3. Insulate non-insulated ends on two of the lead wires to prevent grounding during test.
4. Connect megger test lead onto the remaining exciter armature lead wire. Make certain non-insulated connection does not touch any metal part during test.
5. Connect megger ground lead onto either the generator shaft, fan, or drive hub.
6. Measure exciter armature winding insulation resistance. If insulation resistance is less than one megohm, determine cause of abnormally low insulation resistance.
7. Before operating generator set, solder exciter lead wires onto the exciter rotating rectifier assembly (see Figures 3 and 11).

SECTION 9
DRYING WINDINGS AND REMOVING AND INSTALLING PARTS

DRYING GENERATOR

An excessive accumulation of moisture on the generator windings can reduce the winding insulation resistance. The recommended stator winding insulation resistance test procedure and the minimum allowable insulation resistance is described in Section 8 in this manual.

Where moisture is present and test indicates insulation resistance does not exceed the minimum standard, thoroughly dry out the generator before operating the machine. The following are recommended drying methods.

A. Heat Enclosure

Remove the generator cover. Enclose the generator and insert heating units such as space heaters, lamps, or coils of steam pipe to raise the temperature. Leave a hole at the top of the enclosure to permit the escape of moisture. Temperature within the enclosure should not exceed 93 degrees C or 200 degrees F. The voltage regulator and any electronic components must be removed from the generator when using this method.

B. Forced Air

A portable forced air heater can be used to direct heat into the exciter end of the generator through openings in the endbell. Heat at point of entry should not exceed 93 degrees C or 200 degrees F.

C. Oven

Place the machine in a thermostat controlled oven and bake it at a temperature not to exceed 93 degrees C or 200 degrees F. The voltage regulator and any electronic component accessories must be removed from the generator when using this method.

REMOVING GENERATOR FROM ENGINE

During this procedure be sure to follow the handling precautions described in Section 2 in this manual. Parts are shown on Figures 1 and 2.

1. Remove cover located on end of terminal box and disconnect incoming electrical cables.
2. Loosen cover that surrounds generator frame. Remove drip proof cover and screen from the adaptor located at driven end of generator.
3. Disconnect the generator field leads from the (+) and (-) terminals on the exciter rotating rectifier.
4. Remove exciter rotor retaining bolt from end of generator shaft.
5. Pull exciter rotor off generator shaft. Do not pull on the rectifier assembly or windings.

NOTE: If exciter rotor cannot easily be removed by hand, a 1/4 20 bolt can be threaded into the tapped hole next to the exciter rotor. This action will push the exciter rotor off the shaft.

6. Remove rectangular key from keyway in shaft. Keep key with the exciter armature.
7. Install lifting eye(s) in tapped hole(s) located in the top of the generator frame.
8. Remove bolts that mount the generator onto the generator set base.
9. Where additional space is required to remove coupling bolts, remove fan as follows:
   a. Measure and record distance from the drive plates to the fan. Fan must be located at this distance when it is re-installed
   b. Remove bolts that hold the fan half-sections together, then remove fan.
10. Where engine does not have rear mounting pads, be sure to support engine flywheel housing.
11. Support generator rotor. This may be done by installing (a) a cable around the generator drive hub and attaching cable to a hoist, (b) jack or blocking under the drive hub, or (c), thin wooden or fiber strips in the generator air gap.

NOTE: Where blocking will be placed in the rotor air gap it may be necessary to either remove fan or loosen wrapper cover in order to install rotor support blocking in the air gap.

12. Remove bolts that mount the generator adaptor face onto the flywheel housing.

13. Remove bolts that mount the generator drive plates to the driving ring recess in the flywheel.
14. Attach hoist onto lifting eyes.

CAUTION

Excessive axial misalignment of the rotor can result in equipment damage.

15. Carefully move generator away from the engine flywheel housing and the flywheel. Make certain that drive plates do not bind in flywheel driving ring recess. If the drive plates bind, bearing may be pulled out of the bearing housing.
16. Where rotor was supported by cable and hoist or jack or block under drive hub, remove support from drive hub and follow step 17.
17. Install block across generator adaptor and drive plates. Bolt to adaptor and drive plates to support rotor while transporting the generator.
18. Carefully lift generator off generator set base.

Follow the procedures contained in Section 3 in this manual when mounting generator on the generator set base and coupling the generator to the engine.

REMOVING AND INSTALLING EXCITER ROTOR

The exciter rotor, Figure 2, consists of the exciter armature and the full-wave rotating rectifier assembly. The assembly mounts on an extension of the generator shaft that protrudes beyond the generator endbell. The exciter rotor assembly is held in place on the shaft by a rectangular key on the shaft and a bolt and washer on the end of the shaft. The inside surface on the exciter armature core is pushed against a raised shoulder on the generator shaft.

A. Removing the Exciter Rotor

1. Remove cover located on end of generator terminal box.
2. Disconnect the generator field leads from the rotating rectifier (+) and (-) terminals.
3. Remove exciter retaining bolt from end of generator shaft.

NOTE: If exciter rotor cannot easily be removed by hand, a 1/4 20 bolt can be threaded into the tapped hole next to the exciter rotor. This action will push the exciter rotor off the shaft.

CAUTION

Do not pull on or strike the exciter armature windings.

4. Pull exciter rotor assembly off generator shaft. Pull rectangular key out of the keyway in shaft and keep it with the exciter rotor assembly.

B. Installing Exciter Rotor

1. Install rectangular key in keyway located in generator shaft.
2. Align keyway in the exciter armature core with the key and push exciter rotor onto shaft. DO NOT PUSH OR STRIKE WINDING OR RECTIFIER. MAKE SURE INSIDE EDGE ON ARMATURE CORE IS AGAINST RAISED SHOULDER ON SHAFT.
3. Install exciter retaining bolt on end of shaft. Torque 1/2 inch bolt to 60 foot-pounds.
4. Check exciter air gap. Air gap should not be less than that listed in Table 4. Check to make certain exciter armature core and the exciter field core are axially aligned.
5. Connect generator field leads onto rotating rectifier (+) and (-) terminals (refer to Figure 11).
6. Install cover on terminal box.

REMOVING AND INSTALLING TERMINAL BOX AND ENDBELL

These parts must be removed to service or replace the bearing or when removing the generator rotor. Be sure to

follow the handling precautions described in Section 2 in this manual. Parts are shown on Figures 1 and 2.

A. Removing the Terminal Box and Endbell

1. Remove the side covers and the louvered end cover from the terminal box.
2. Disconnect incoming electrical cables and conduit. Disconnect stator leads.
3. Disconnect electrical wiring from voltage regulator and other controls mounted within the terminal box.
4. Remove the exciter rotor, comprised of the exciter armature and rotating rectifier assembly. Follow the steps given in procedure titled "Removing the Exciter Rotor."
5. Remove fiber wire retaining ring.
6. Remove parts that mount onto the back plate of the terminal box and the endbell.
7. Remove cover that surrounds the generator frame.
8. Place rotor support blocking in the generator air gap.
9. Remove bolts that mount the terminal box and the endbell onto the generator frame.
10. Remove terminal box.
11. On larger generators, attach hoist onto endbell. Take up slack but do not lift generator.
12. Pry endbell loose from pilot recess located in the frame endring.
13. Pull endbell straight back to position where bearing outer race is out of the bearing housing at the center of the endbell.
14. Remove endbell.
15. Some units may have circular fiber spacers located in the bearing housing section of the endbell. If this is the case, be sure to install spacers when reinstalling endbell.
16. Inspect and clean rust and dirt from the mounting face on endbell and the bearing housing. Remove any metal burrs.
17. Wipe a thin coat of grease in the bearing housing section of the endbell.

B. Installing Terminal Box and Endbell

During this procedure be sure to follow the handling precautions described in Section 2 in this manual. Refer to Figure 1 and the wiring diagram provided with the generator set.

1. Where generator was provided with circular spacers in the bearing housing section of the endbell, install the spacers.
2. Inspect to make certain bearing housing and mounting face on endbell is free of rust, dirt, and metal burrs.
3. Wipe thin coat of grease in bearing housing section in endbell.
4. Lift endbell into alignment with the bearing and carefully push bearing housing section on endbell over the outer race of the bearing.
5. Place endbell over end of shaft and turn endbell to position where lead wire hole in endbell aligns with lead wires. Pull stator leads through opening in the endbell. Make certain generator field leads are along wireway on shaft.
6. Push endbell bearing housing over the bearing outer race.
7. Mount terminal box and endbell onto the generator frame using hex head bolts and washers. Watch to make certain endbell fits evenly into pilot recess, and sequentially tighten bolts. Torque bolts according to recommended torque for SAE 5 cap screws given in Table 2.
8. After generator has been coupled to the prime mover, remove rotor support blocking from generator air gap.
9. Install fiber wire retaining ring.
10. After generator has been coupled to the prime mover, install the exciter rotor as described in procedure titled "Installing Exciter Rotor."
11. Mount voltage regulator and controls.
12. Connect electrical wiring according to appropriate wiring diagram.
13. Before operating generator set, check to make certain unit is connected correctly and terminals are tight and insulated.
14. Remove tools and shop cloths.
15. Install covers and guards.

REMOVING AND INSTALLING BEARING

If the bearing needs to be removed for any reason, always install a new bearing. Remove and install bearing according to the general procedure that follows. Be sure to follow the handling precautions described in Section 2 in this manual.

1. Disconnect wiring and remove the exciter rotor, terminal box, and endbell. Refer to the preceding "Terminal Box and Endbell Removal" instructions and procedure titled "Removing the Exciter Rotor."
2. Remove fiber wire retaining ring.
3. Remove bearing with suitable puller.
4. Apply a thin coat of clean lubricating oil or anti-seize lubricant to the pressure fit on the rotor shaft.
5. Heat the new bearing in an oven to a maximum temperature of 225°F.

CAUTION

Under no circumstances should pressure be applied to the outer race of the bearing, as permanent bearing damage could result.

6. Make certain generator field leads are in proper position in the wireway along the generator shaft. Then using asbestos gloves, install the bearing over the end of the shaft. Using metal or fiber pipe with I.D. larger than the shaft, push against bearing inner race until bearing seats against the raised shoulder.

NOTE: The bearing should slide on the shaft and be seated without excessive force. If the bearing binds on the shaft before being fully seated, a piece of tubing slightly larger than the shaft diameter can be placed over the shaft and the bearing can be slid in place by tapping lightly on end of tubing with a soft mallet. Care must be taken to ensure pressure is applied to the inner race only.

7. Allow bearing to cool.
8. Install endbell and terminal box. Follow the "Endbell and Terminal Box Installation" instructions.
9. Remove rotor support blocking from air gap.
10. Install fiber wire retaining ring.
11. Install exciter rotor as described in procedure titled "Installing the Exciter Rotor."
12. Mount parts in terminal box and connect wiring as shown on the wiring diagram supplied with the generator set.
13. Remove tools and shop cloths.
14. Install covers.

REMOVING AND INSTALLING GENERATOR ROTOR

Generator parts are shown on Figure 1.

Be sure to follow handling precautions described in Section 2 in this manual. Rotor may be removed as described in the procedure that follows. BE EXTREMELY CAREFUL TO MAINTAIN CLEARANCE BETWEEN METAL PARTS AND WINDINGS.

A. Removing Rotor

1. Disconnect power and remove incoming electrical cable and conduit. Disconnect generator ground wire.
2. Remove end and side covers from terminal box.
3. Remove exciter rotor as described in the procedure titled "Removing the Exciter Rotor."
4. Install wooden rotor support blocking in the generator air gap.
5. Disconnect wiring and remove the voltage regulator and other parts mounted within the terminal box.

NOTE: Where a clear space approximately the same distance in length as the generator exists beyond the outboard or exciter end of the generator, unit need not be removed from the generator set base. If this is the case, and stator repair is not required, proceed to step 8.

6. Remove generator from the engine as described in procedure titled "Removing Generator From Engine." Be sure to follow precautions contained in Section 2 in this manual.

7. Transport generator to area that provides sufficient room for rotor removal through exciter end of unit. Approximately the same distance as length of generator must exist beyond exciter end of unit. Be sure to follow handling precautions contained in Section 2 in this manual.
8. Remove generator covers.
9. Remove fiber wire retaining ring.
10. Remove terminal box and endbell as described in the "Terminal Box and Endbell Removal" instruction. Be sure to follow handling precautions contained in Section 2.
11. Remove drive plates from the drive coupling hub.
12. Remove fan as follows:
    a. Measure from inside face on coupling hub to outside face on fan hub. Record this distance. Fan must be positioned according to this measurement when it is reinstalled.
    b. Remove bolts that secure the fan half-sections together, then remove fan.
13. Bend 16 gauge or heavier sheet metal to fit in air gap and extend beyond frame endring or use several plywood strips or wood that will extend through air gap and out past the frame endring.
14. Lift both ends of the rotor slightly and insert the blocking described in step 12. Be sure to maintain air gap.
15. Place blocks between the blocking and frame endring at the exciter end. Blocks should be of sufficient height to keep strips clear of windings.
16. Lower generator rotor onto blocking.
17. Carefully slide rotor part way out through exciter end of unit.
18. After rotor has been placed in position where field (rotor) poles are partially beyond frame endring, proceed to next step.
19. Attach cable around exciter field poles be careful to keep cable away from windings.
20. Attach hoist onto cable and, while balancing rotor, move generator rotor out of stator. Be careful to maintain air gap.

B. Installing Rotor

Installation procedure, in general, is the reverse of removal procedure. Torque bolts according to recommended torque for SAE 5 cap screws shown in Table 2. Be sure to position fan according to measurement made during removal procedure step 11. Be sure to follow precautions given in Section 2 in this manual. Follow alignment in section and measurements contained in Section 3.

INSTALLING REPLACEMENT SURGE SUPPRESSOR

Refer to Figure 3.

To remove defective surge suppressor: Use a screwdriver to loosen surge suppressor lead connections on the heat sinks. Pull leads free. Remove surge suppressor disk from slot on rectifier hub. Removal may be difficult as surge suppressor is secured with silicone rubber adhesive.

To install replacement surge suppressor: Install disk of surge suppressor in slot on rectifier hub and secure with silicone rubber adhesive. Take care not to block the tapped hole on the rectifier plate near the surge suppressor slot. Attach surge suppressor lugs to connections on the heat sinks and tighten connections.

SECTION 10
FIGURES AND TABLES

GENERAL

The drawings, electrical schematics, and tables contained in this section are included to aid in the installation and maintenance of this equipment. The overall electrical connection diagram supplied with the generator set should be followed when connecting the stator lead wires, voltage regulator, and any other operating controls provided with this unit.

Table 1
Generator Voltage - Standard Kamag Generators

Connection (See Note)	Voltage Range (By Adjustment of voltage control rheostat)	
	50 Hertz	60 Hertz
3 Phase series wye (Phase-to-Phase)	340 to 400	408 to 490
3 Phase parallel wye (Phase-to-Phase)	170 to 200	204 to 245
3 Phase series delta (Phase-to-Phase)	196 to 230	236 to 283
Single Phase 3 wire (Line-to-Line)	196-230	236 to 283

NOTE: Phase-to-neutral voltage for 3-phase wye connections are 58% of line-to-line voltages listed. Line-to-neutral voltage for 3 wire single phase is one-half the line-to-line voltage listed.

NOTE:

a. Diameter tolerance of driving ring pilot bore B is plus 0.005, minus 0.000; maximum eccentricity is 0.005 total indicator reading (see footnote b); face runout is 0.0005 maximum total indicator reading per inch of diameter.

b. Eccentricity between driving ring pilot bore B and pilot bearing bore L is not to exceed 0.008 total indicator reading.

c. K is length of bore for pilot bearing; L is nominal diameter of bearing. Diameter and fit are to suit installation. Maximum eccentricity is 0.005 total indicator reading (see footnote b).

d. Tapped holes should be threaded in accordance with UNC Class 2B tolerances of the SAE Standard, Screw Threads-SAE J475.

Table 4
Minimum Air Gap for Kato Brushless Exciter

Exciter Rotor (Armature) Diameter (in inches)	Minimum Air Gap (in inches)
5 3/4	0.014
9 7/8	0.014
12/ 1/2	0.018
16 1/4	0.035

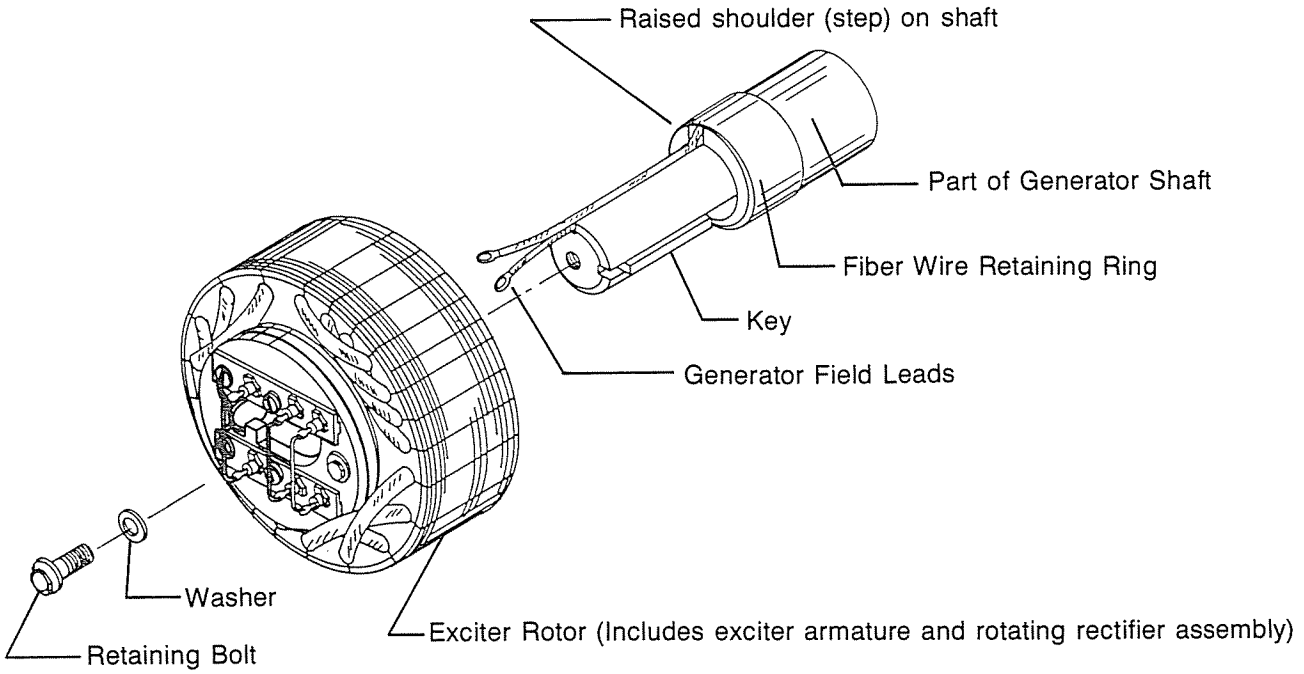

Figure 2 Exciter Rotor Installation

NOTE: Exciter and Generator Field Interwiring is shown on Figure 11.

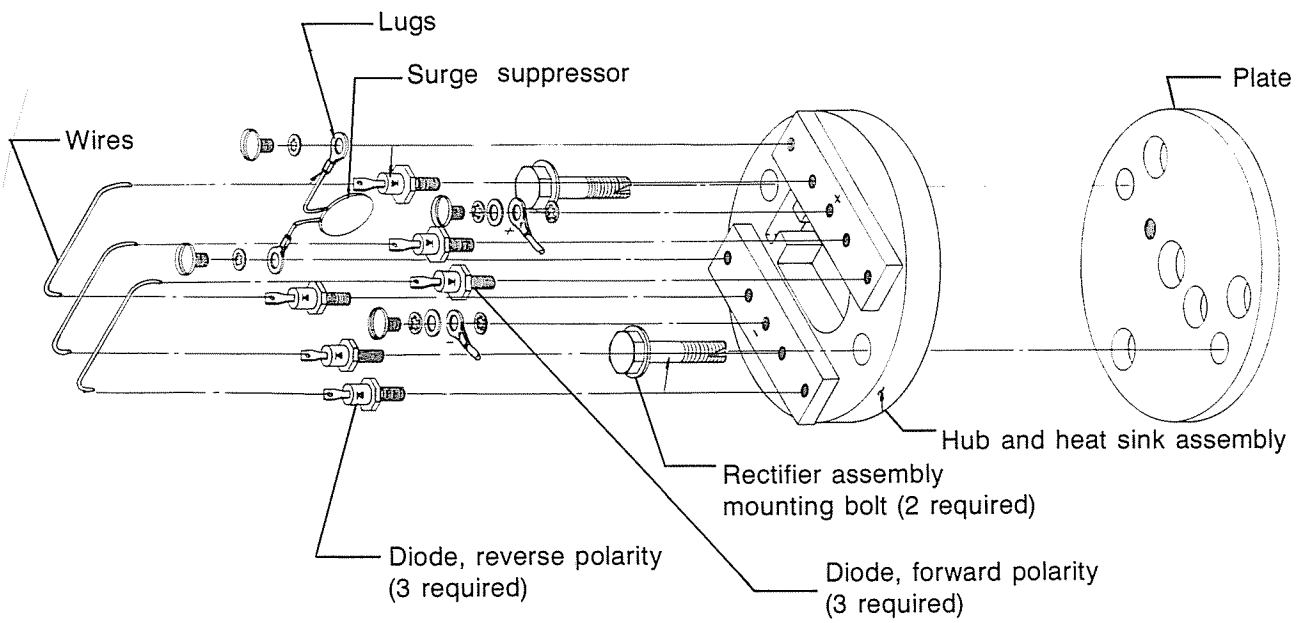

Figure 3 Rotating Rectifier

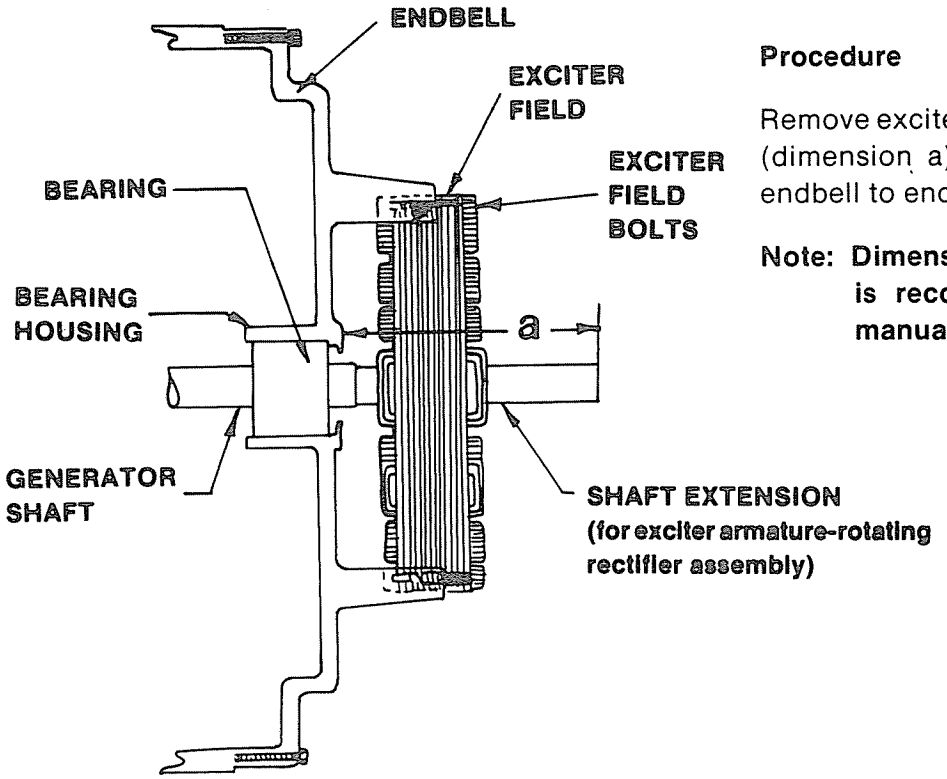
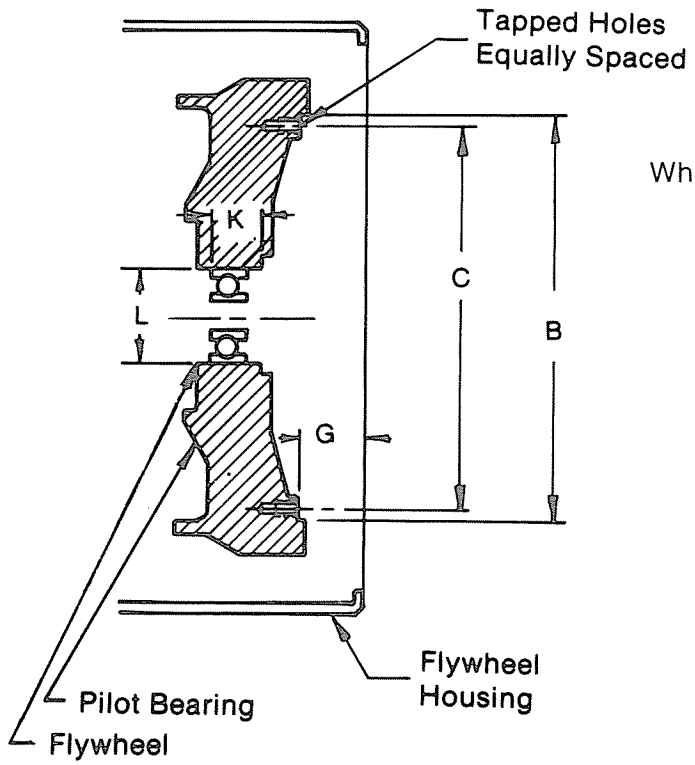


Procedure

Remove exciter rotor unit. Measure length (dimension a) from bearing housing on endbell to end of shaft.

Note: Dimension (a) measured at factory is recorded in section 1 in this manual.

Figure 4 Extension of Generator Rotor Shaft For Mounting of Exciter Rotor Assembly

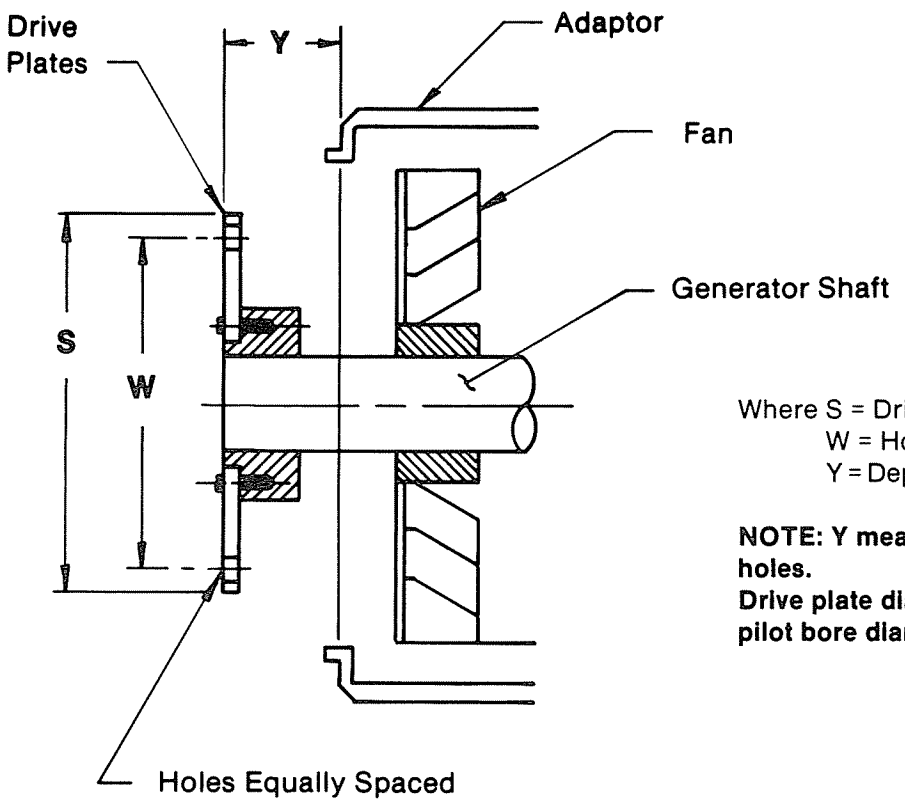


Where: B= Driving Ring Pilot Bore Diameter
C= Hole Centers
G= Depth from flywheel housing face
L= Pilot Bearing Bore
K= Length of bore for pilot bearing

Note: G measured from face on flywheel housing with tapped holes

See Table 3

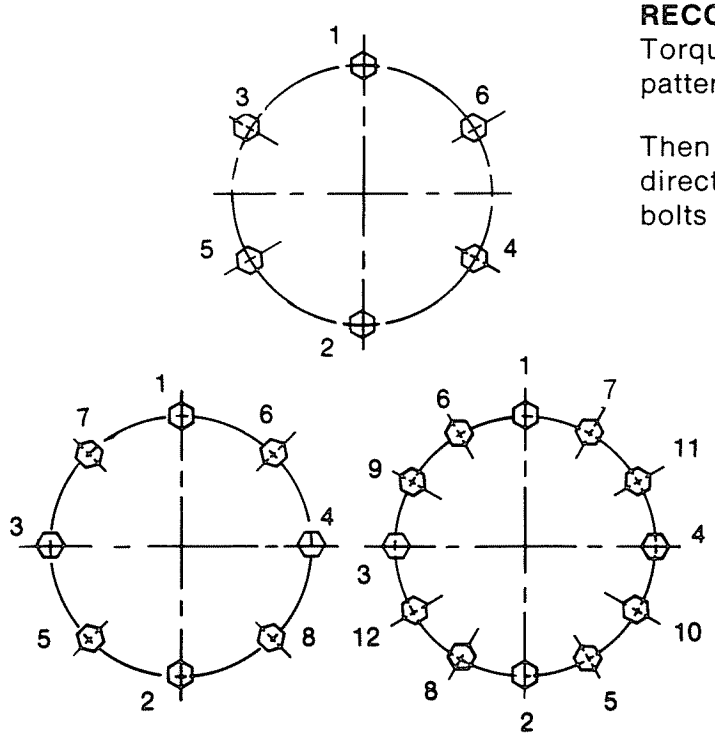
Figure 5 SAE Flywheel



Where S = Drive Plate Diameter
W = Hole Center
Y = Depth from Drive Plate to Face on adaptor

NOTE: Y measured to face on adaptor with tapped holes.
Drive plate diameter S equals flywheel driving-ring pilot bore diameter B + .000
- .008

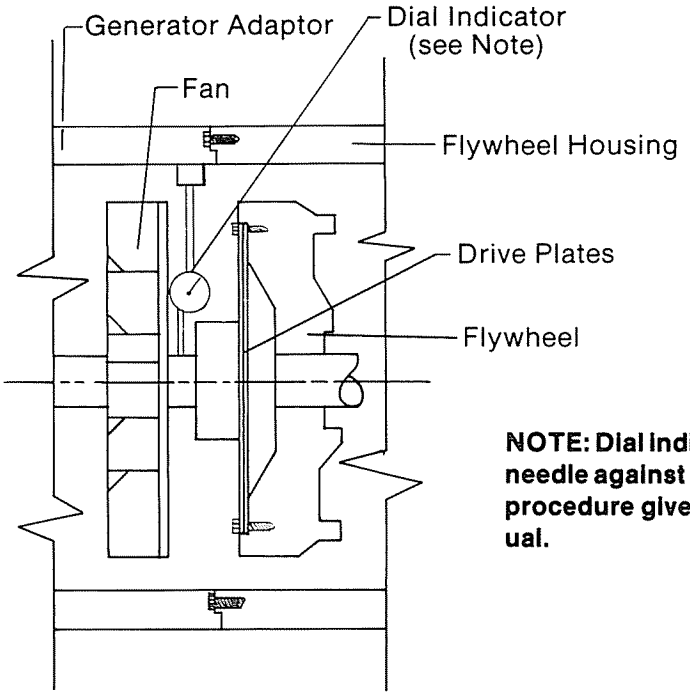
Figure 6 Single Bearing Generator Adaptor and Drive Plates



RECOMMENDED PROCEDURE
Torque bolts in sequence according to bolt pattern.

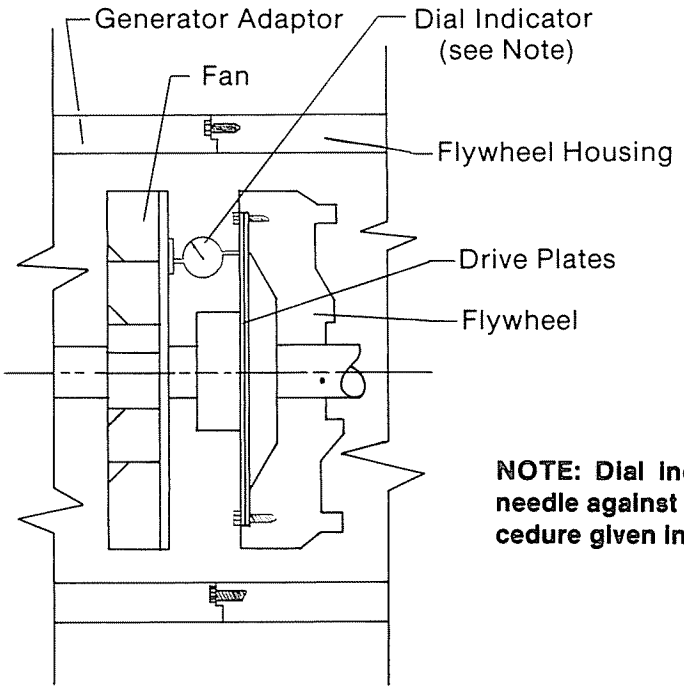
Then check torque in each bolt in clockwise direction around the bolt circle to ensure all bolts are properly torqued.

Figure 7 Recommended Torque Sequence For Circular Bolt Pattern



NOTE: Dial indicator base on adaptor and needle against shaft or drive hub. Refer to procedure given in Section 3 in this manual.

Figure 8 Checking Rotor Eccentricity



NOTE: Dial indicator base on fan and needle against drive plates. Refer to procedure given in Section 3 in this manual.

Figure 9 Checking Angular Alignment

WARRANTY

Kato Engineering warrants that its products will perform as specified in bonafide quotations or Kato publications, providing such products are properly installed, properly cared for, and properly operated under normal environmental conditions.

Standard products manufactured by Kato Engineering are warranted to be free from defects in workmanship and material for a period of one year in operation or 18 months from date of shipment, and any products which are defective in workmanship or material will be repaired or replaced at the option of Kato Engineering. Final determination as to whether a product is actually defective rests with Kato Engineering. The obligation of Kato Engineering hereunder shall be limited solely to repair and replacement at its factory, of products that fall within the foregoing limitations and shall be conditioned upon receipt by Kato Engineering of written notice within the warranty period of any alleged defects or deficiency. No products shall be returned to Kato Engineering without its prior consent. In no case will Kato Engineering accept shipping charges incurred either through return of defective items to its factory or return of repaired or replacement items to the user. Kato Engineering cannot assume responsibility or accept invoices for unauthorized repairs to its components even though defective. In the case of components, parts or units purchased by Kato Engineering the obligation of Kato Engineering shall not exceed the settlement that it is able to obtain from the supplier thereof.

The life of the products of Kato Engineering depends to a large extent upon the type of usage. Kato Engineering makes no warranty as to period of service nor as to fitness of its products for specific applications by the buyer. In no event will Kato Engineering be liable for consequential or incidental damages or any expense incurred by the Buyer due to use or sale of products sold by Kato Engineering.

The foregoing warranty is exclusive and in lieu of all other warranties expressed or implied, including but not limited to any warranty of merchantability or of fitness for a particular purpose.

This Warranty does not apply to experimental or developmental products.

WARNING

Personal injury, death and/or equipment damage may occur if these instructions are not followed. All local and national codes must be followed. Power must be disconnected before servicing.

FOREWORD

This manual contains pertinent instructions for proper installation, operation, service and trouble shooting of your brushless alternator. The location of each section can be found in the table of contents. This manual is supplied with each alternator and should be reviewed by the installer, operator and maintenance personnel to insure safe and proper use.

SAFETY FIRST

All electrical and mechanical service should be performed by qualified personnel only. Ensure the installation meets all applicable safety and electrical codes. If you are not sure of the procedures or instructions, seek qualified help before proceeding.

- Power must be disconnected before servicing. Lock out all closing circuits. Place warning labels on circuit breakers and controls used to connect alternator to other alternators or utility mains to avoid accidental closure.
- Disable engine starting circuits before carrying out any maintenance.
- Do not operate the alternator with the terminal box, access covers or any of the protective covers or screens removed.
- Do not lift an entire generator set (alternator and engine) by the lifting provisions provided on the alternator. Personal injury or damage to the equipment may result.
- Observe all WARNING/CAUTION notices.

ELECTRICAL SHOCK CAN CAUSE PERSONAL INJURY OR DEATH

Katolight Service - Master Repair Manual - Page 628

PRINCIPLES OF OPERATION

Self Excited

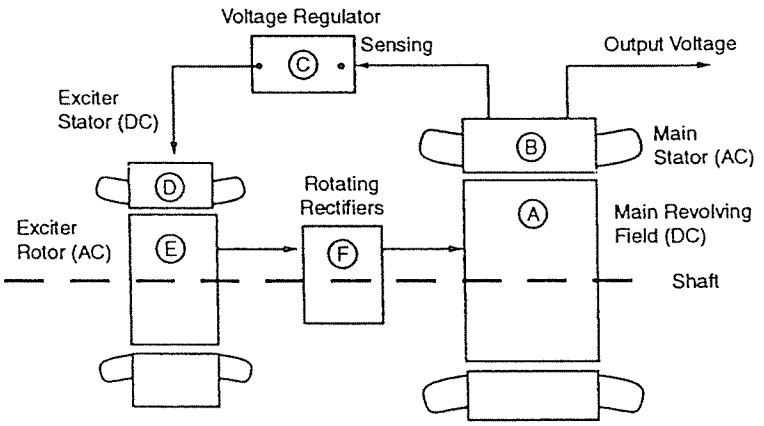
The prime mover drives the revolving field assembly **(A, F, E)**.

As the revolving field assembly rotates, residual magnetism in the main revolving field **(A)** produces a small A.C. voltage in the main stator **(B)**.

The regulator **(C)** rectifies this small voltage and applies it to the exciter field **(D)**. A three phase voltage is then generated by the exciter rotor **(E)** which is rectified into DC by the rotating rectifier assembly **(F)**. This DC voltage then appears at the main revolving field which causes a higher A.C. voltage in the main stator.

The output voltage from the main stator is sensed by the regulator and compared to a reference level. The regulator controls the exciter field excitation to maintain a precise output voltage from the main stator.

The voltage build-up process takes place usually in less than one second.



Permanent Magnet (PM) Excited

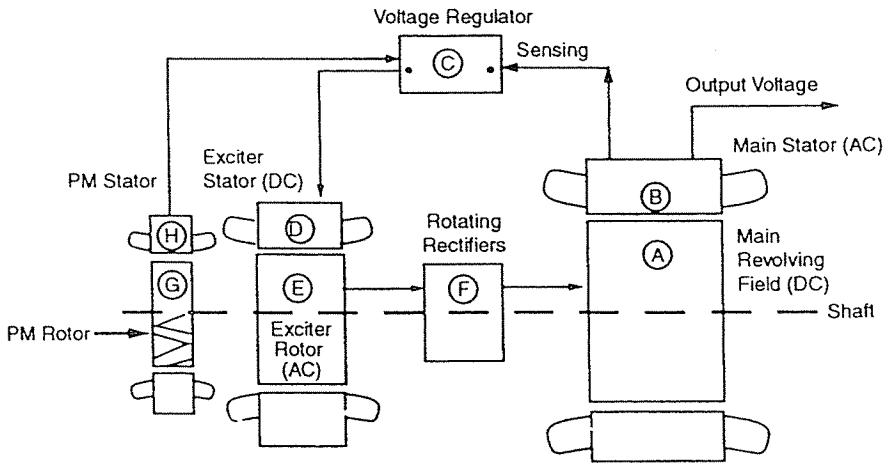
The prime mover drives the revolving field assembly **(A, F, E, G)**.

As the PM rotor **(G)** rotates, magnetism produces AC voltage in PM stator **(H)**.

The regulator **(C)** rectifies this voltage and applies it to the exciter field **(D)**. A three phase voltage is then generated by the exciter rotor **(E)** which is rectified into DC by the rotating rectifier assembly **(F)**. This DC voltage appears at the main revolving field **(A)** which generates AC voltage in the main stator **(B)**.

The output voltage from the main stator is sensed by the regulator and compared to a reference level. The regulator controls the exciter field excitation to maintain a precise output voltage from the main stator.

The voltage build-up process takes place usually in less than one second.



APPLICATION

The alternator is typically supplied as a component part to be used in a generator set. Warning/ Hazard labels are to be attached by the genset assembler or end user after the alternator has been attached to the engine, painted, etc. It is the responsibility of the genset assembler to be sure the correct labels are attached and are clearly visible.

The alternator is normally rated for operation in a maximum 40°C (104°F) ambient temperature, and at a maximum elevation of 1000 meters (3300 feet) above sea level. Should the alternator be required to operate in an ambient above nameplate rating or an altitude above 1000 meters, refer to the factory or the alternator set representative.

The alternators are typically of open, air-ventilated, screen protected construction and are not suitable for mounting outdoors unless adequately protected in an enclosure. Space heaters are recommended for storage and standby duty to keep the winding insulation in good condition.

When installed in a weather protecting or sound attenuating enclosure, the enclosure should be designed such that air intake to the alternator is not impeded and does not exceed the ambient temperature rating. The ingress of moisture and dirt should be avoided.

Single bearing alternators are supplied with SAE flywheel housing adapter and flexible drive disc. They are designed to match the engine flywheel housing and flywheel. Alignment of single bearing alternators is critical. A substantial base with engine and alternator mounting pads is required.

Torsional compatibility of the generator set and/or installation is the responsibility of the generator set manufacturer, his representative, the installer and/or the end user. Upon request, the necessary data for torsional analysis will be supplied.

Various types of non-linear loads consisting of Silicon Controlled Rectifiers (thyristors) present special problems for alternators. The problems are alternator stator heating and interference with the alternator voltage regulation system. The most commonly encountered SCR loads are battery chargers used with Uninterruptable Power Supplies (UPS Systems), solid state reduced voltage motor starters and variable frequency drive motor speed controls. Alternators typically require derating and isolation of the regulator through the use of a permanent magnet (PM) exciter, or filters.

RECEIVING

Before accepting your alternator it should be examined carefully for any damage that may have occurred during transit. If damage is noticed, the shipment should be refused and claim should be filed against the transportation company. Once acceptance of the shipment is made, the alternator is the property of the receiver and any damage due to handling will be the responsibility of the receiver.

HANDLING

Before unpacking your alternator, read the instruction card. If supplied, the lifting provisions should be used when lifting the alternator. Remove the alternator from the skid by using a suitable overhead hoist and lifting vertically.

LONG TERM STORAGE

If the alternator is to be stored, it should be in a clean, dry area that is not subject to large variations in temperature and/or humidity. Space heaters are recommended for storage and standby duty to keep the winding insulation in good condition.

INSTALLATION

Preparation

Before assembling the alternator to the prime mover, a visual inspection should be made. Inspect the output lead connections to make certain they are in agreement with the appropriate diagram in the back of this manual. Inspect all leads and wiring for insulation breaks, cracks and loose connections. All mounting bolts should be checked. All shipping supports, strips, tags and skids must be removed. **If the alternator has been in storage, the windings should be checked for ground resistance. See Insulation Testing Section.**

Inspection

The main stator winding should be checked for insulation resistance to ground with a megohmmeter (megger). This is particularly important if the alternator has been in storage.

For proper insulation testing, see Insulation Testing. If a low megohm reading is recorded, it is an indication of a wet, dirty and/or grounded winding. Clean and dry the windings using one of the methods listed for Moisture Removal.

CAUTION

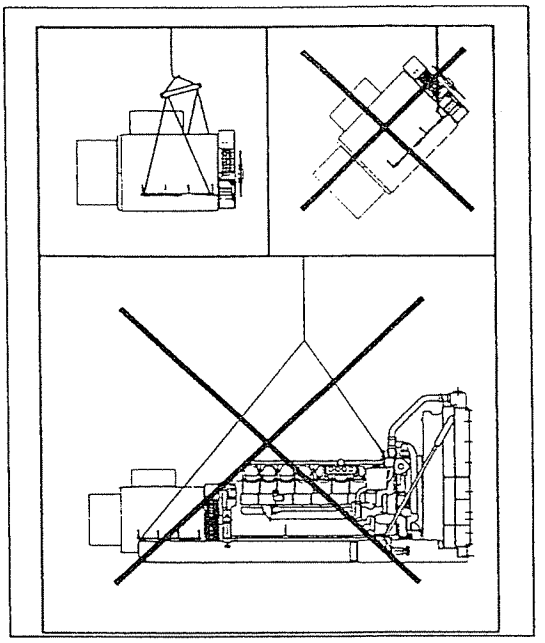
Before using the megohmmeter, read the instructions thoroughly on Insulation Testing. Failure to do so can result in equipment damage.

Lifting

Lifting provisions are provided to allow lifting with an overhead crane or hoist and lifting clevis. Chains of suitable length and capacity must be used. A spreader bar is recommended to avoid damage to the terminal box and altrnator finish. **Design restrictions prohibit the center of gravity from being centered between the lifting points, the alternator may not remain horizontal while lifting. Care must be taken to avoid personal injury or equipment damage while lifting.**

CAUTION

Incorrect lifting or inadequate lifting capacity may result in personal injury or equipment damage. Do NOT lift an entire generator set by the lifting provisions provided on the alternator.



Single Bearing Mounting

All single bearing alternators are shipped with an SAE adaptor, which matches the engine's flywheel housing and SAE drive discs which match the engine's flywheel. Alignment is critical. If necessary shim the alternator feet to ensure alignment of the machined surfaces.

Alternator to Engine

Before assembly, make sure all mounting surfaces are clean.

Install two guide pins in the engine flywheel. Using a suitable hoist, position the alternator so the drive discs mate with the engine flywheel. Remove the guide pins and install mounting bolts and lock washers through the alternator drive discs into the engine flywheel. Torque bolts according to the torque specification. Also install bolts and lock washers through the adaptor into the flywheel housing.

Install mounting bolts to secure the alternator to the mounting base.

Install the fan guard screen.

CAUTION

Screen must be in place to prevent personal injury.

Output Connections

For proper alternator output connections, select the appropriate diagram with the correct number of leads and desired output voltage range. Be sure to connect all identically marked output leads together. Final adjustment of the alternators output voltage to the desired level is achieved with the regulator voltage LEVEL adjust rheostat.

Insulation Testing

CAUTION

Electronic parts, such as regulators, diodes, etc. will be damaged if a megohmmeter is applied across their terminals to ground.

The following procedure is recommended to check the alternator winding resistance to ground. A megohmmeter, designed for insulation resistance testing, using 500 VDC to test the winding should be used. The minimum acceptable resistance to ground for a new alternator is found as follows:

$$\text{Resistance} = \frac{\text{Connected Voltage}}{1000} + 1\text{Megohm}$$

Main Stator

Disconnect regulator sensing leads 20, 22 and 24 from the terminal block. With the output leads disconnected from the load or breaker, reconnect the output leads together. Measure the insulation resistance from any one of the output leads U1 (T1), V1 (T2) or W1 (T3) to ground with a megohmmeter. Make sure the regulator input leads (20, 22 and 24) and the main stator leads U1 (T1), V1 (T2) and W1 (T3) do not touch ground to prevent accidental grounding.

If the reading is below the minimum acceptable value for a new alternator, it is an indication of a dirty, wet or grounded winding. Clean the winding per preventative Maintenance and Cleaning Section and dry the winding per Moisture Removal Section. If after cleaning and drying, the winding resistance is still unacceptable, repair or replace the stator.

Main Rotor

Disconnect the two main rotor leads from the exciter diode assembly. Measure the resistance from one lead to ground (connect one lead of the megohmmeter to the shaft or internal fan). Make sure the main rotor leads do not touch any other part during this test. If the reading is below the minimum acceptable value for a new alternator, it is an indication of a dirty, wet or grounded winding. Clean the winding per Preventative Maintenance and Cleaning Section and dry the winding per Moisture Removal Section. If after cleaning and drying, the rotor resistance reading is still unacceptable, repair or replace the main rotor.

Exciter Stator

Disconnect the exciter stator input leads, F1 and F2, from the regulator. Measure the resistance from one input lead to ground with a megohmmeter. Make sure the input leads do not touch ground during this test. If the reading is below the minimum acceptable value for a new alternator, it is an indication of a dirty, wet or grounded winding. Clean the winding per Preventative and Maintenance and Cleaning Section and dry the winding per Moisture Removal Section. If after cleaning and drying, the winding resistance is still unacceptable, repair or replace the exciter stator.

Exciter Rotor

Disconnect all three exciter rotor leads from the exciter diode assembly. Verify the lead locations for proper reconnection. Using a megohmmeter measure the resistance from one lead to ground (connect the ground lead of the megohmmeter to the exciter diode bracket). Make sure none of the three exciter rotor leads touch ground during this test. If the reading is below the minimum acceptable value for a new alternator, it is an indication of a dirty, wet or grounded winding. Clean the winding per Preventative Maintenance and Cleaning Section and dry the winding per Moisture Removal Section. If after cleaning and drying, the winding resistance is still unacceptable, repair or replace the exciter rotor.

Moisture Removal

Alternators and generator sets which have been in storage and subject to variations in temperature and/or humidity, should be dried thoroughly before operation. The following methods are recommended:

Forced Heated Air

Forced heated air from a portable heater or some other suitable source can be used to dry an alternator. The heated air entering the alternator should not exceed 150°F (65.6°C) at the closest electrical winding. Drying can be accomplished by running the alternator at no load and with the regulator disconnected (no excitation) while directing the heated air into the exciter end of the alternator.

Space Heaters

If the alternator is supplied with space heaters, refer to the connection diagram on the inside side cover of the conduit box for instructions. Energize the space heaters and allow them to operate for 24 hours to insure proper drying.

Baking Oven

Note: All electronic parts, including the regulator, must be removed before baking. The alternator can be placed in a baking oven and dried. The temperature of the oven should not exceed 190°F (88°C).

Main Stator Short Circuit Method

WARNING

Personal injury, death and/or equipment damage may occur if these instructions are not followed.

First, disconnect the exciter stator leads F1 and F2 from the voltage regulator terminal strip. Next connect a DC power source (battery) to the F1 and F2 leads.

Note: Connect the positive (+) terminal to F1 and the negative (–) terminal to F2.

The DC source should be about 12 volts DC (an adjustable source is preferred). With the DC source in place short all three output leads U (L1), V (L2), W (L3) together. Start the alternator and bring it up to rated speed. Measure the short circuit current in each lead with a clamp on ammeter. The amp readings should be about 80% of the full load amp rating on the name plate. If the amp readings exceed the rating the DC source must be adjusted. After the alternator has run about an hour the winding resistance to ground should be measured using a megohmmeter. This procedure should be repeated every one to two hours until a consistent resistance reading is obtained. This reading must be equal to or greater than the following megohmmeter reading.

$$\text{Resistance} = \frac{\text{Connected Voltage}}{1000} + 1 \text{ Megohm}$$

After this procedure is complete, disconnect the DC source and reconnect F1 and F2 to the regulator terminal strip.

Note: If moisture removal is required then the alternator insulation should be completely tested using the method covered in Insulation Testing Section.

OPERATION

Pre-Operation Inspection

Before the initial operation of the generator set, a pre-operation inspection should be given. Recheck the output connections for correct connection and that all leads are insulated. Recheck the regulator connections for proper and tight connections. Visually inspect the alternator for any foreign material which must be removed (tools, shop rags, packing material, etc.). Make sure that all drip covers, screens and conduit box covers are in place and all bolts are tight. Check air intake, ventilation path and exhaust for obstructions.

Engine Warm-up/Cool Down

If your alternator is supplied with a MagneTek regulator, it has built in protective circuitry for some abnormal conditions. The regulator resets when input power to the regulator is interrupted for approximately one minute. If the generator set must run at low speed idle or other abnormal condition for extended time a relay or switch may be required. Close the relay or switch, allowing power to the regulator when normal operation begins.

Output Voltage Adjustment

The Voltage LEVEL Adjust is incorporated in the MagneTek regulator allowing for voltage adjustment. To adjust the output voltage, turn the adjustment with a screwdriver CW to increase the voltage and CCW to decrease the voltage.

Generator Set Start-up

Before starting the generator set read the automatic voltage regulator instructions and follow the steps outlined for proper regulator adjustment.

No Load Operation

1. Open the main circuit breaker to disconnect the alternator output leads from the load. Adjust the voltage regulator per the voltage regulator instructions.

2. Start the prime mover and bring it up to full load rated speed. If a voltage regulator switch is used, close the switch after the engine is warmed up and at rated speed, this will apply excitation. When this switch is not used, alternator voltage will build up automatically.

CAUTION

If a MagneTek regulator is not used, refer to the regulator manufacturers manual for correct start-up precautions, as damage may occur.

3. Adjust the output voltage per the voltage regulator instructions.

If any of the following conditions occur, stop the prime mover and refer to the troubleshooting section of the voltage regulator manual.

a. Overvoltage (+20% or more)

b. No voltage build up

c. Undervoltage (-25% or less)

d. Fluctuating voltage

Operation With Load

1. Apply the load to the alternator output leads by closing the circuit breaker.

2. Adjust the full load engine speed, 1800 RPM (60Hz) or 1500 RPM (50Hz) for four pole alternators.

3. Verify the voltage regulation is within ±1%. If it is not within these limits refer to the voltage regulator instructions.

4. Open the main circuit breaker to remove the load before stopping the prime mover.

Exciter Field Flashing (Self Excited Only)

The output voltage of the self excited alternator is initially produced by residual magnetism. Residual magnetism can be lost as a result of vibration or rough handling which may occur in shipping or storage. If the residual magnetism is lost no voltage will be produced and exciter field flashing is required. To flash the exciter field, shut the generator set down. Disconnect the exciter stator input leads F1 and F2 from the regulator terminal strip. Connect a 12 volt DC battery to the F1 and F2 exciter leads. The F1 lead must be connected to the positive (+) terminal and the F2 lead must be connected to the negative (-) terminal.

CAUTION

The correct connection must be made F1 to Positive (+) and F2 to Negative (-). If connections are reversed, the regulator could be damaged when the generator set is restarted.

This will remagnetize the exciter stator and will allow output voltage build-up when the generator set is restarted.

Katolight Service - Master Repair Manual - Page 634

SERVICE

Bearings

Sealed bearings are normally supplied for maintenance free operation. If excessive noise or vibration develops after a period of time this may be due to bearing wear. Replace the bearing if damaged, seals show sign of wear or loss of grease is observed.

If regreaseable bearings are supplied. Grease the bearings every 2000 hours of operation or every 12 months with 2 ounces of Chevron SRI #2 or compatible grease. Replace the bearings if excessive noise or vibration develops.

Anytime the alternator is disassembled the bearings should be checked for damage. It is recommended that the bearing be replaced during any major overhaul.

Windings

Winding condition can be checked using the insulation testing instructions found in the Installation Section of this manual.

Preventative Maintenance and Cleaning

Heat, moisture and airborne contaminants are the most common contributors to alternator problems. Alternator life can be extended if it is periodically checked for overloads, unbalanced loads, proper alignment, moisture and dirt build-up.

Overloads and unbalanced loads will cause overheating in the alternator. Overheating will cause insulation breakdown and eventual failure. These conditions must be corrected by redistributing the unbalanced load or removing the excess load.

Proper alignment between the alternator and the prime mover is critical for efficient vibration free operation. Vibration caused by misalignment can cause premature failure to both prime mover and alternator.

Dust, dirt and other airborne contaminants when allowed to accumulate will cause alternator failure. This type of contamination will cause insulation breakdown and overheating by restricting air flow. A build up of contaminants will also "blanket" the windings and other electronic components causing overheating. Some airborne contaminants will form a conductive path to ground which will cause failure.

Moisture by itself or in the presence of airborne contaminants will cause alternator failure by forming a conductive path to ground. If the alternator is operating in an area where airborne contaminants and/or moisture are present, the alternator should be cleaned and dried periodically.

Cleaning Methods

When alternators are stored and/or operate in an area where contaminants are present in the air, they should be cleaned periodically. To clean the alternator, disassemble and follow one of the following procedures. After cleaning the alternator, it should be dried (See moisture removal section) and tested (See insulation testing section) before being put back into service.

Dry Surface Dirt

Dry surface dirt can be removed with a dry soft cloth and/or with dry compressed air. If the dirty areas are accessible, a dry soft cloth can be used to remove the dirt. If the areas are not accessible or if the cloth is not effective in removing the dirt, dry compressed air can be used (air pressure should not exceed 30 PSI).

CAUTION

Protective goggles and dust mask should be worn when using compressed air to remove dust or dirt from inside the alternator. Compressed air or dry cloth should not be used when contaminants are extremely abrasive, like metal dust or metal chips.

Dry or Loose Dirt

Dry, loose, or abrasive dirt in hard to reach areas can be removed by brushing the dirt free and then vacuuming it out of the alternator. Do not use a metal bristle brush. It may cause insulation damage.

Hard Dirt Deposits

Hard dirt deposits can be removed from the winding by using walnut shells(I2 - 20 mesh) as a mild abrasive with compressed air and shell blasting the winding. After shell blasting, vacuum the winding and inside of the alternator clean.

Oily or Greasy Dirt

Oily or greasy dirt can be removed by using a solvent and soft cloth. The only recommended solvents to be used are Chlorothene or Naphtha (mineral spirits).

WARNING

Using any solvent other than the ones recommended may cause insulation deterioration and will void any warranty.

After cleaning the windings and/or electronic components dry with low pressure, moisture free compressed air.

WARNING

When using solvent read the Manufacturer's instructions for proper use. Protective gloves should be worn. Only use in an area with adequate ventilation. Do not breathe vapors. Do not use around open flame. Failure to follow these instructions may cause personal injury or death.

Disassembly / Inspection

Alternator from Engine

Warning

Personal injury, death or equipment damage may occur if all instructions are not followed.

1. Disconnect all power from the generator set before proceeding.
2. Remove terminal box access cover.
3. Disconnect all load leads from the alternator output leads or the bus bars. Also disconnect any conduit or lead ducts attached to the terminal box.
4. Before removal from the prime mover, position the main rotor, if possible, such that a full pole face is at the bottom center.

Warning

To rotate rotor, do not bar the fan as this may result in equipment damage or personal injury.

5. Carefully check that there are no connections, leads or guards that will interfere with the removal of the alternator. Uncouple and remove any such obstructions.
6. Attach a suitable overhead hoist to the genset and adjust hoist to remove all slack from the lifting chain/sling.
7. Lift the genset high enough to place a reinforcement block between the engine flywheel housing and base thereby supporting the engine.

Warning

Insure the engine fan does not hit the radiator or radiator shroud.

8. Remove the drip cover (if specified) and screen assembly from the alternator.
9. Place polypropylene strips or similar material between pole faces and stator laminations to minimize contact and damage.
10. Support the alternator rotor with a suitable sling.
11. Remove the bolts holding the drive discs and the flywheel together and the bolts holding the alternator SAE adapter to the flywheel housing. Separate the alternator from the engine.

Rectifier / Heatsink Assembly

1. With the exciter cover removed, locate and disconnect all terminals on the rectifier / heatsink assemblies.
2. Using an ohmmeter, measure the resistance between one of the AC terminals (1,2,3) and the (-) terminal on the negative (-) rectifier/heatsink assembly. Make sure the heatsink is not grounded. Note the resistance reading and reverse the ohmmeter probes. Note the second resistance reading. One of these resistance readings should be high and one should be low. Repeat this procedure with the other two AC terminals and the (-) terminal on the negative (-) rectifier/heatsink assembly. Replace the rectifier/heatsink assembly if defective.
3. Repeat the above procedure with each of the 3 AC terminals and the (+) terminal on the positive (+) rectifier/heatsink assemble.
4. Using an ohmmeter, measure the resistance between terminals of each varistor with the varistors disconnected. The resistance should be high. Typically a failed varistor shows visible signs of stress.

Exciter Assembly

1. Disconnect exciter leads from the regulator inside the terminal box.
2. Locate and remove the four bolts in the end of the shaft that hold the spacer/washer. Remove the spacer/washer.
3. With the spacer/washer removed slide the exciter rotor off the shaft.
4. Remove the four bolts that hold the exciter stator to the bearing bracket. Mark the location of the exciter for reassembly and remove the exciter stator.

Exciter Assembly Inspection

Inspect the exciter stator and rotor windings. Check for any cuts, scrapes, loose, frayed or burnt windings or damaged leads. Check the windings for open or grounded circuits.

Permanent Magnet Exciter Assembly

1. Disconnect PM leads from the regulator inside the terminal box.
2. Slide the PM rotor assembly off the shaft. The highly magnetic rotor will attract the stator. Avoid contact between the rotor and stator that could damage the windings.
3. Remove the bolts that hold the PM stator to the bearing bracket. Mark the location of the PM stator for reassembly. Remove the PM stator.

Katolight Service - Master Repair Manual - Page 636

Permanent Magnet Exciter Inspection

1. Inspect the PM stator windings and leads for any cuts, scrapes, loose frayed or burnt windings. Check the windings for open or grounded circuits.
2. Check the PM rotor assembly for broken, damaged or loose magnets. The rotor assembly must not be dismantled.

Bearing Bracket

1. Support the bearing bracket by using a sling attached through the openings in the bracket.
2. Remove the bearing retainer bolts and bearing retainers.
3. Remove the bearing bracket bolts and washers.
4. Remove the bearing bracket by inserting jackscrews into the jackscrew holes. Alternate the tightening of the jackscrews ¼ to ½ turn at a time so the bracket comes off slowly and evenly. Do not allow the main rotor to drop onto the main stator.

Bracket Inspection

1. With the bracket removed, clean the bracket bearing cavity.
2. Check the bracket for cracks and rough spots on the machined surfaces. Check the bearing bore for rough spots, burrs, rust and excessive wear. Replace the bracket if found defective.

Bearing Inspection

1. With the bearing bracket removed and the bearing on the shaft, check for damage or wear.
2. If the bearing needs to be replaced, remove the bearing using a suitable bearing puller.

Main Rotor Assembly

CAUTION

At all times caution should be used to prevent damage to the shaft bearing surfaces and other closely machined shaft fits. Care should be taken to avoid contact between the rotor and stator. Do not damage the windings. The rotor should be rested on some form of blocking once removed form the stator. Do not rest lifting devices on windings or laminations.

1. With the rectifier, permanent magnet exciter, main exciter and bearing bracket removed locate and remove the flexible drive discs.
2. Locate a rotor support tool or heavy gauge pipe on the exciter end shaft extension. Using suitable slings at the rotor support tool and drive hub, ease the rotor out the drive end of the stator until at least half of the rotor core is protruding out of the stator. Support the drive end so the sling and rotor support tool can be removed.
3. Using a suitable sling around the rotor core and supporting the drive end ease the rotor clear of the stator.

Fan Inspection

1. Visually inspect the cooling fan for cracked, deformed or broken fan blades. If any of these conditions exist, replace the fan..

Main Stator

1. With the alternator disassembled clean the main stator windings if necessary.
2. Inspect the main stator winding and output leads for any cuts, scrapes, and loose, frayed or burnt windings.
3. Check the main stator winding for open or grounded circuits.
4. Inspect all machined surfaces for rough spots, rust or burrs. Also check the frame assembly for cracks, dents or other damage.

Assembly

Note: *All bolts and nuts must be torqued according to the torque values given in the torque specifications. Loctite 242 must be used in the assembly of all bolts, nuts and screws except electrical fasteners.*

Bearings

1. Bearings must be mounted on rotor shaft prior to rotor assembly into the stator.
2. Heat the bearings prior to installation onto the shaft to a maximum temperature of 212°F (100°C) preferably with a bearing induction heater.

Caution:

Do not overheat the bearing. Damage may occur which will shorten the bearing life.

Main Rotor

1. Before assembly, be sure the main rotor and stator assemblies are clean.
2. Use a rotor support tool and suitable hoist/sling to lift and support the rotor assembly.
3. Slowly insert the rotor assembly bearing end first, until the rotor and stator laminations line up. Position the main rotor, if possible, such that a full pole face is at the bottom center.

Bearing Bracket

1. Allow bearing to cool to room temperature.
2. Install guide pins into the bearing bracket boltholes in the main stator.
3. Support the bearing bracket by using a sling attached through the bracket openings.
4. Apply a film of grease to the surface of the bearing bore and shaft hole to aid in assembly, prevent corrosion and help seal out contaminants after assembly.
5. With non-sealed bearings the bearing cavity should be approximately 40% filled with grease.

6. Slowly ease the bracket into place until the bearing rests inside the bearing cavity.
7. Install bearing retainers.
8. Bolt the bearing bracket to the main stator assembly.

Permanent Magnet Exciter Assembly

1. Attach the PM stator to the bearing bracket.
2. Place the main rotor leads in the shaft slot.
3. Carefully slide the PM rotor onto the shaft. Avoid contact between the rotor and stator that could damage the windings or the permanent magnets.
4. Connect the PM stator leads to the voltage regulator.

Exciter Assembly

1. Assemble the exciter stator to the bearing bracket with four retaining bolts and washers.
2. Connect the exciter stator leads to the voltage regulator.
3. Place the revolving field leads in the shaft slot.
4. Slide the exciter rotor assembly onto the shaft.
5. Route the main rotor leads through the spacer/washer.
6. Attach the exciter rotor assembly using the spacer/washer and four retaining bolts to the end of the shaft.

Rectifier / Heatsink Assembly

1. Assemble the rectifier/heatsinks to the exciter rotor. Make sure heatsinks are not grounded.
2. Connect one set of exciter rotor leads to the AC terminals on the positive (+) rectifier/heatsink and one set to the negative (-) rectifier/heatsink. Phase sequence is not a consideration.
3. Connect the main rotor leads to the (+) and (-) terminals on the rectifier/heatsinks. Polarity is not a consideration.

Regulator / Accessories

1. Reconnect automatic voltage regulator, regulator ground lead, exciters, temperature detectors and accessories.
2. Use cable ties to secure all leads out of the way and away from all rotating parts.

Alternator to Engine

1. Before assembly, make sure all mounting surfaces are clean.
2. Attach flexible drive discs to coupling hub.
3. Install guide pins in the engine flywheel. Using a suitable hoist, position the alternator so the drive discs mate with the engine flywheel. Remove the guide pins and install the mounting bolts and lockwashers through the drive discs into the engine flywheel. Torque bolts according to the torque specifications.
4. Install bolts and lock washers through the adapter into the flywheel housing.
5. Install mounting bolts to secure the alternator to the mounting base.

Terminal Box

1. Reconnect power leads.
2. Use cable ties to secure all leads out of the way and away form all rotating parts. Secure leads to prevent abrasive wear due to vibration.
3. Reconnect any conduit or lead ducts to the terminal box.

Covers and Screens

1. Install all access covers, screens and drip covers.

Caution

All access covers and screens must be in place to prevent personal injury and equipment damage.

Recommended Spare Parts

The following are recommended spare parts. For critical applications a set of these service replacement parts should be kept with the alternator.

1. Rectifier assembly kit.
2. Automatic voltage regulator.
3. Bearing.

When ordering replacement parts the alternator serial number and nameplate information along with the part description should be given. Refer to the alternator cut-a-way drawing in the back of this manual for replacement parts identification.

Introduction

Forward

This manual contains instructions for installing, operating and maintaining Kato Engineering ac brushless revolving field generators. These generators are manufactured in many sizes and ratings and with various options.

Lubrication information, electrical connection drawings, dimensional drawings and parts listings for your model are contained in the manual package as supplementary information and are the specific source of information for making connections and ordering replacement parts. Information about optional components of your generator may also be contained as a supplement.

Please read this manual in its entirety before unpacking, installing, and operating your generator.

Safety instructions

In order to prevent injury or equipment damage, everyone involved in installation, operating and maintenance of the generator described in this manual must be qualified and informed of the current safety standards that govern his or her work.

While "common-sense" prevention of injury or equipment damage cannot be completely defined by any manual (nor built into any piece of equipment), the following paragraphs define warnings, cautions, and notes as they are used in this manual:

Warning: Warnings identify an installation, operating or maintenance procedure, practice, condition, or statement that, if not strictly followed, could result in death or serious injury to personnel.

Caution: Cautions identify an installation, operating or maintenance procedure, practice, condition, or statement that, if not strictly followed, could result in destruction of or damage to equipment or serious impairment of system operation.

Note: Notes highlight an installation, operating or maintenance procedure, condition, or statement and are essential or helpful but are not of known hazardous nature as indicated by warnings and cautions.

Ratings/description

Nameplates, which are located on the side of the generator, include serial and model number as well as rating information and bearing and lubrication information.

Construction and operating principles

Stator

The stator consists of the supporting frame, core, and armature windings.

The stator core is made from laminations, thin sheets of electrical steel that are stacked and held in place by steel endrings and support bars. The rings and bars are welded to or are part of the steel frame. Base mounting plates are welded to the bottom of the frame. The base mounting plates allow the assembly to be mounted on the genset base.

The windings (coils) are constructed of layered and insulated copper wire. The coils are inserted in the core slots, connected together, and the entire assembly is vacuum-pressure impregnated with resin. Stator leads terminate in standard connection lug or strap terminals for ease of connection to the load.

Rotor

The main rotor assembly is the rotating field. It consists of windings in a core, which is in turn mounted on a steel shaft. The exciter armature assembly and optional permanent magnet generator (PMG) rotor are also mounted on the shaft as are the fan(s) and other optional accessories. The core consists of laminations, thin sheets of electrical steel, which are stacked together. The core makes the salient poles (four, six, eight or 10). With six or more poles, the poles are typically attached to a center hub.

The rotor windings consists of insulated magnet wire wound around each pole. V-blocks between each pole keep the rotor windings in place. Damper windings consist of copper or aluminum rods that are inserted through each pole surface and are brazed to copper or aluminum damper end plates at each end of the lamination stack. The end plates are brazed to adjacent poles to form a continuous damper winding. The ends of the windings are supported with bars or aluminum pole shoes. The rotor either has resin applied during the winding process or is vacuum-pressure impregnated with resin.

The shaft is made from high-strength rolled or forged steel and machined to accommodate all the rotating generator components. Keyways in the shaft ensure precise positioning of the rotor, exciter armature, and PMG rotor as well as drive couplings. On the exciter side, the shaft has a slot or hole in its centerline for running the rotor leads from the rectifier to the main rotor windings.

Bearings

The generator may contain one or two bearings. Bearings are typically ball or roller type and are either 1) heavy duty double shielded bearings, which are typically used on smaller generators and are greased for life or 2) regreaseable bearings, which contain fill and drain ports for

easy lubrication. Sleeve bearings are optional on some designs. A supplementary instruction will be included in the manual package for sleeve bearings if they are applicable to this generator.

Connection boxes

The main lead connection box houses the load lead terminals. In addition, the generator may have auxiliary connection boxes for connecting temperature detector outputs, space heater connectors, and sensing outputs.

Excitation system

The excitation system consists of the exciter stator assembly and the exciter armature assembly:

The exciter stator assembly consists of windings in a core. The core is made from steel laminations that are stacked and welded together. The main exciter stator coils are placed in slots in the core and form alternate negative and positive poles. The entire assembly is either mounted to the end bracket or mounted in a frame, which is mounted to the end bracket. The stator is a stationary field, which is powered by the voltage regulator.

The exciter armature assembly is keyed onto the generator shaft. The assembly consists of two subassemblies: the exciter armature and the rotating rectifier. The exciter armature assembly contains steel laminations that are stacked and keyed on the shaft or on to a sleeve. (The exciter sleeve is keyed to the generator shaft.) A three-phase winding is inserted into slots in the laminations. The coils are held in place by insulating wedges. The coil extensions are braced with tape. Output leads from the winding are connected to the rotating rectifier assembly.

The rotating rectifier is a three-phase full wave bridge rectifier, converting the ac from the exciter armature to dc, which is transferred to the main rotor windings. Two aluminum steel plates, each containing three rotating rectifier diodes, are mounted on each side of an insulating hub to form the negative and positive terminals. The plates also act as heat sinks for the diodes.

Excitation system functional overview: Exciter field control is established by the strength of the exciter field current developed by the voltage regulator system. The dc voltage and current levels of the exciter field signal from the voltage regulator varies depending upon the generator output voltage and the loading of the output lines (see Figure 1).

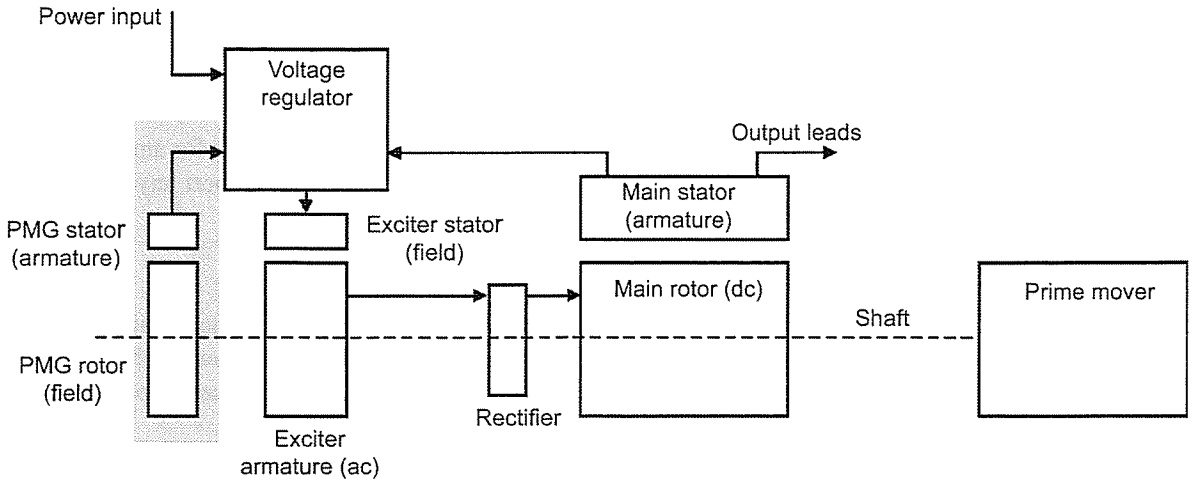

Figure 1: Overview of excitation system (with an optional PMG)

Optional PMG system

The permanent magnet generator (PMG) system consists of the PMG stator and PMG rotor:

The PMG stator is a stationary armature and is located within the stator assembly that also contains the exciter stator or is a separate stator mounted next to the exciter stator. The PMG stator consists of steel laminations. The laminations are held in place by steel compression rings and are welded to the frame bars of the exciter-PMG frame. The PMG windings are placed in slots in the laminations. Insulating wedges are inserted at the top of each slot to hold the coils in position.

The PMG rotor consists of rectangular permanent magnets and cast pole tips secured to a steel hub with nonmagnetic stainless steel bolts. The PMG rotor is keyed to the shaft and secured with a nut and lock washer.

PMG system overview: The PMG system functions as a pilot exciter, providing power to the automatic voltage regulator power supply. The PMG is an ac generator that uses permanent magnets in the rotor instead of electromagnets to provide the magnetic field (see Figure 1).

Other options

Other options include, but are not limited to, space heaters, filters, and temperature sensing devices.

Installation

Warning: *Be alert at all times when installing, operating and maintaining the generator. Avoid contact with the uninsulated metal parts of the generator. Most casualties occur from faulty ground connections on portable electrical equipment and failure to ground stationary equipment.*

Test all portable devices frequently to prove that a solid electrical circuit exits from the metal frame though the grounding conductor, in the electrical cord, to the grounding contact in the attachment plug. Do not use electrical equipment with frayed, burned or damaged cords. Always take extreme care when moving the generator. Be careful to not strike objects or personnel.

Apply lifting force to structural points specifically provided for lifting. Do not use the enclosure lifting holes to lift the whole unit. Use lifting means adequate to the weight. Observe lifting notices attached to the generator. Failure to observe these instruction can result in injury and damage to the generator.

Caution: *Do not attempt to transport a single-bearing generator without maintaining proper rotor support and with the exciter rotor assembly removed. Failure to observe this warning can result in equipment damage.*

Caution: *Blocking or restriction of normal air flow into or out of the generator may cause damage to the electrical windings.*

Receiving inspection

Before accepting a shipment, examine the packaging for any sign of damage that might have occurred during transit. Report any damage to the transportation company and Kato Engineering.

Unpacking and moving

If the generator is received during cold weather, reduce condensation on cold surfaces and failure due to wet windings by allowing the generator to reach room temperature before removing the protective packing.

Unpack the generator carefully to avoid scratching painted surfaces. Do not remove the protecting lubricant from the shaft end or dive plates. Inspect for loosely mounted components and the presence of moisture. Inspect to make certain foreign material such as crating nails, loose bolts or packing material, which may have fallen into the machine during unpacking, are removed. If damage is noted, determine the extent of damage and immediately notify the transportation company claims office and Kato Engineering. Be sure to give complete and accurate details when reporting damage.

Move the generator by attaching an overhead hoist to the eyebolts installed on the generator frame or by lifting the generator from underneath the skid with a forklift.

Single-bearing generators are shipped with the exciter rotor assembly removed from the shaft and a support mounted across the drive disc to support the rotor.

Location

Locate the generator in an area so it complies with all local and industrial regulations. Locate it in a clean, dry, well-vented area or area that is suitable for the generator enclosure. Make sure it is easily accessible for inspection and maintenance.

Protect generators operating intermittently in very damp locations with space heaters. Slowly warm generators placed in operation after being subjected to very low temperatures to prevent excessive condensation. Check winding resistance before placing the generator in operation (see instructions below).

Base design

The type of base to be used will depend upon the nature of the installation site. However, the generator base must be rigid, level, and free from vibration. Mounting holes must be larger than the fasteners to allow for alignment.

Assemble to prime mover, alignment

Follow either the two-bearing alignment (if your generator model has two bearings but no adapter to bolt to an engine flywheel housing), two-bearing close-coupled alignment (if your generator model has two bearings and an adapter for bolting to a flywheel housing), or single-bearing alignment (if your generator has one bearing and drive plates). Consult the factory for belt or gear drive alignment).

Two-bearing alignment

Follow the tolerances specified by the coupling manufacturer when they are less than described in this manual.

Use shims, if necessary, between the mounting pad and the base to properly level and align the generator to the prime mover.

Install the coupling(s) on the generator and engine drive shafts in accordance with their installation procedures. Use a straight edge and a thickness gauge for rough alignment as shown in Figure 2. Check for angular and parallel alignment as follows:

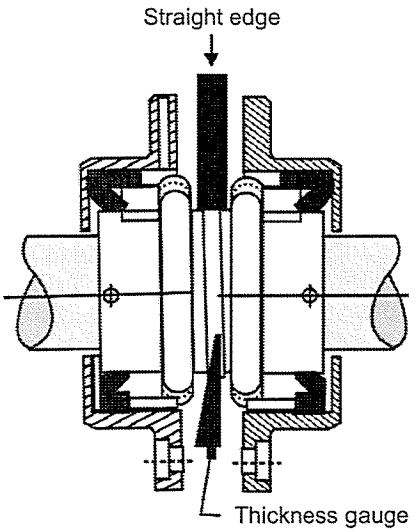

Figure 2: Rough alignment

Angular alignment: Fasten a dial indicator to one of the coupling halves, and scribe the position of the dial button on the face of the opposite coupling half as shown in Figure 3. Rotate both shafts simultaneously, keeping the finger or button on the indicator at the reference mark on the coupling hub. Note the reading on the indicator dial at each one quarter revolution.

A variation of readings at different positions will indicate how the machine needs to be adjusted to obtain a maximum misalignment of 0.001 inch for each inch of the coupling hub's radius, total indicator runout. Place or remove slotted shims from under the front or rear engine or generator mounting pads and/or shift the front or back half of one component from side to side until the components are properly aligned. Tighten the mounting bolts, and recheck alignment.

Notes: *Mounting of the indicators must allow complete rotation of the prime mover.*

Use dial indicators that are rigid so indicator sag won't be a factor. Using the shortest offset distance of the indicator bracket will reduce the effects of indicator droop or sag.

During alignment, you may also need to compensate for engine expansion due to heating. Generator expansion is generally not considered a factor.

If the genset is moved to a different location, check alignment before startup.

Caution: *Do not pry on the generator fan.*

Caution: *Generators equipped with sleeve oil bearings must have oil added to the bearing prior to rotation. See the bearing manual.*

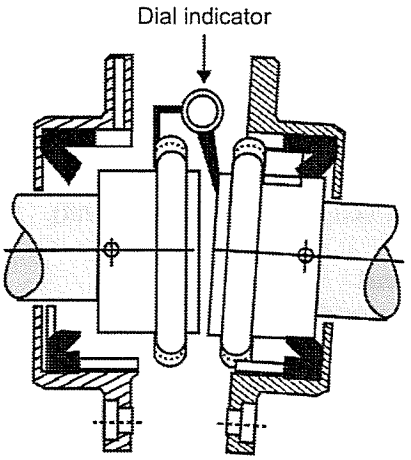

Figure 3: Angular alignment

Parallel alignment: Fasten a dial indicator to one of the coupling halves, and scribe the position of the dial button on the top of the opposite coupling half as shown in Figure 4. Rotate both shafts simultaneously, keeping the finger or button on the indicator at the reference mark on the coupling hub. Note the reading on the indicator dial at each one quarter revolution. A variation of readings at different positions will indicate how the machine needs to be adjusted to obtain a maximum misalignment of 0.002 inch. Place or remove slotted shims from under all of the engine or generator mounting pads and/or shift one component from side to side until the components are properly aligned. Tighten the mounting bolts, and recheck alignment.

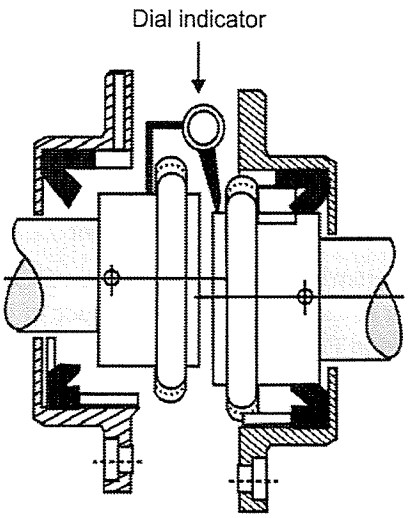

Figure 4: Parallel alignment

Two-bearing close-coupled alignment

Check the engine flywheel housing pilot's radial and face runout by mounting a dial indicator and measuring the flywheel to the flywheel housing as shown in Figure 5. See Table 1 for maximum allowable runout.

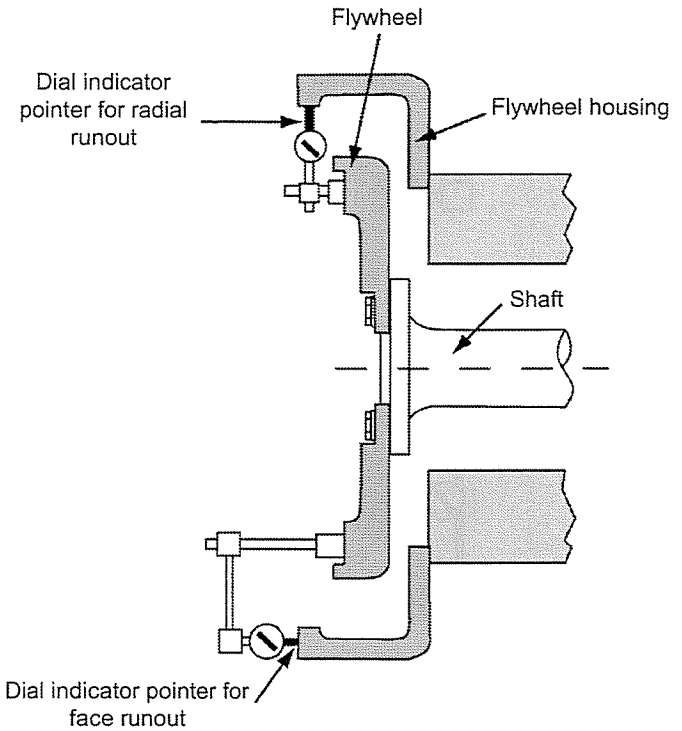

Figure 5: Flywheel housing check

SAE housing number	Housing inside dia.	Allowable runout (TIR)
6	10.500	0.002
5	12.375	0.003
4	14.250	0.003
3	16.125	0.004
2	17.625	0.004
1	20.125	0.005
0.5	23.000	0.005
0	25.500	0.006
00	31.000	0.007

Table 1: Maximum allowable flywheel housing runout (inches)

Notes: *Mounting of the indicators must allow complete rotation of the prime mover.*

Use dial indicators that are rigid so indicator sag won't be a factor. Using the shortest offset distance of the indicator bracket will reduce the effects of indicator droop or sag.

During alignment, you may also need to compensate for engine expansion due to heating. Generator expansion is generally not considered a factor.

If the genset is moved to a different location, check alignment before startup.

Caution: *Do not pry on the fan.*

Caution: *Generators equipped with sleeve oil bearings must have oil added to the bearing prior to rotation. See the bearing manual.*

Check the engine flywheel's radial and face runout by mounting a dial indicator and measuring the flywheel housing to the flywheel as shown in Figure 6. See Table 2 for maximum allowable runout.

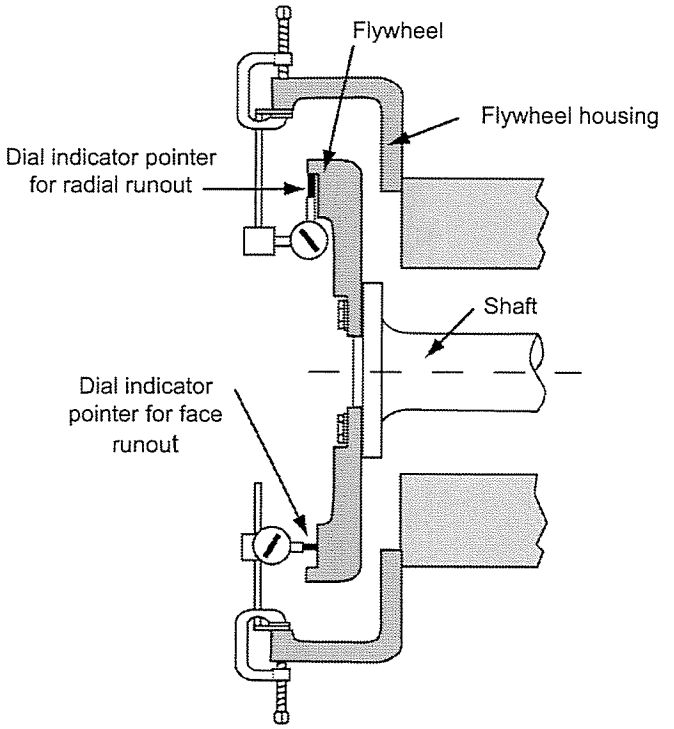

Figure 6: Flywheel check

Pilot diameter	Allowable runout (TIR)
6.5	0.002
7.5	0.002
8	0.002
10	0.003
11.5	0.003
14	0.004
16	0.005
18	0.005
21	0.006
24	0.007

Table 2: Maximum allowable flywheel runout (inches)

Check the generator adapter's radial and face runout by mounting a dial indicator on the generator shaft or coupling as shown in Figure 7. The maximum radial and face runout on the generator adaptor must not exceed 0.010 inch.

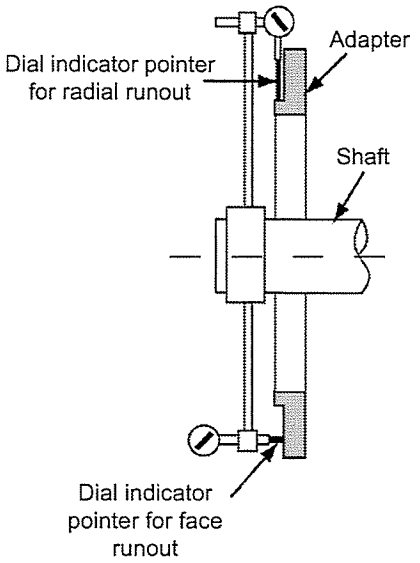

Figure 7: Generator adapter check

Check the generator coupling's radial and face runout by mounting a dial indicator to the generator adapter as shown in Figure 8. The maximum radial and face runout on the coupling must not exceed 0.003 inch.

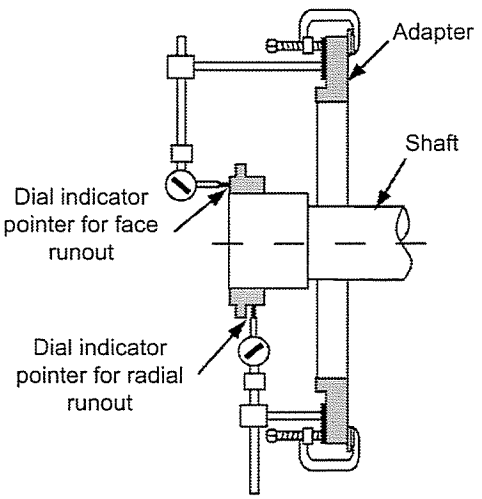

Figure 8: Generator coupling check

Install the portion of the coupling that fits into the engine flywheel following the manufacturer's recommended procedures and in accordance with engine manufacturer's specifications. Check the coupling's radial and face runout by mounting a dial indicator to the engine flywheel housing as shown in Figure 9. The maximum radial and face runout on the coupling must not exceed 0.004 inch.

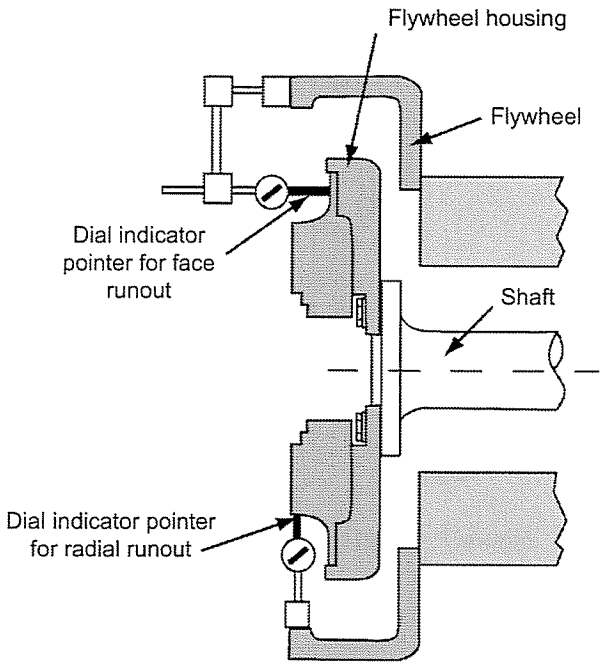

Figure 9: Engine coupling check

Measure and record the engine crank shaft end float and generator end float. Set the engine end float to the manufacturer's recommended position for alignment. Verify the generator end-float is set at a position of one half of the measured distance or at a position that will allow full thermal growth of the generator shaft when operated at rated temperatures.

Mount the generator on the skid, and move the generator to within 0.010 inch of the engine. Place two 0.010-inch shims in the horizontal (9 o'clock and 3 o'clock) positions between the generator adapter and the engine flywheel housing. Raising the rear, exciter end of the generator as necessary, place two 0.010-inch shims in the vertical (6 o'clock and 12 o'clock) positions between the generator adapter and the engine flywheel housing. This will give a good starting point for alignment. Remove the vertical shims at this time. (If necessary, mark holes to be drilled on the base, and remove the generator at this time.)

Mount a dial indicator on the generator shaft or half coupling to the flywheel radial surface for parallel alignment as shown in Figure 10. Mount a dial indicator on the flywheel coupling to the face of the generator half coupling for angular alignment as shown in Figure 10. Align the engine by rotating the prime mover in 90-degree increments and measuring total indicator runout. Tighten the generator to the base before taking each set of readings. Raise or lower the generator by adding or removing shims under the machined feet.

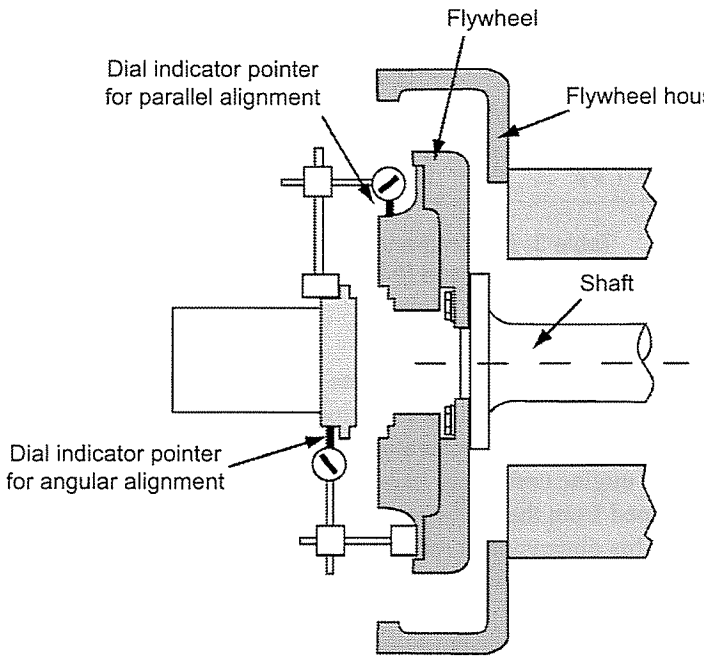

Figure 10: Alignment check

Following the final generator adjustment and runout check, remove the horizontal shims from the adaptor flywheel housing, and move the generator all the way to the adaptor. Then tighten the fasteners. Recheck alignment. Make sure angularity (face) total indicated runout does not exceed 0.001 inch per inch of generator shaft diameter and parallel (radial) total indicated runout does not exceed 0.003 inch.

Note: *Clearances between the adaptor pilot and the flywheel housing recess are designed to meet the tolerance of 0.001 to 0.015 inches.*

Torque the fasteners to the value shown in Table 3.

Shank diameter (in.)	SAE 5 steel torque	SAE 8 steel torque
1/4	9	13
5/16	18	28
3/8	31	46
7/16	50	75
1/2	75	115
9/16	110	165

Table 3: Recommended cap screw torque (ft-lbs)

Notes: *Mounting of the indicators must allow complete rotation of the prime mover.*

Use dial indicators that are rigid so indicator sag won't be a factor. Using the shortest offset distance of the indicator bracket will reduce the effects of indicator droop or sag.

During alignment, you may also need to compensate for engine expansion due to heating. Generator expansion is generally not considered a factor.

If the genset is moved to a different location, check alignment before startup.

Caution: *Do not pry on the generator fan.*

Caution: *Generators equipped with sleeve oil bearings must have oil added to the bearing prior to rotation. See the bearing manual.*

Single-bearing alignment

Before assembling the generator to the prime mover, remove the exciter cover and adapter cover. Remove the blocking holding the drive discs to the adapter. Also make sure the generator bearing end clearance is not less than the total engine crankshaft axial movement plus 1/16 inch. The generator is shipped from the factory with 1/8-inch minimum bearing end clearance. (This dimension is recorded on the Factory Recorded Dimensions sheet, packaged with the generator.)

Measure the distance from the end of the exciter shaft extension to the bearing housing on the endbracket (dimension A in Figure 11). This dimension is recorded on the Factory Recorded Dimensions sheet, packaged with the generator. If the dimensions do not match, move the rotor axially relative to the stator until the dimensions are equal.

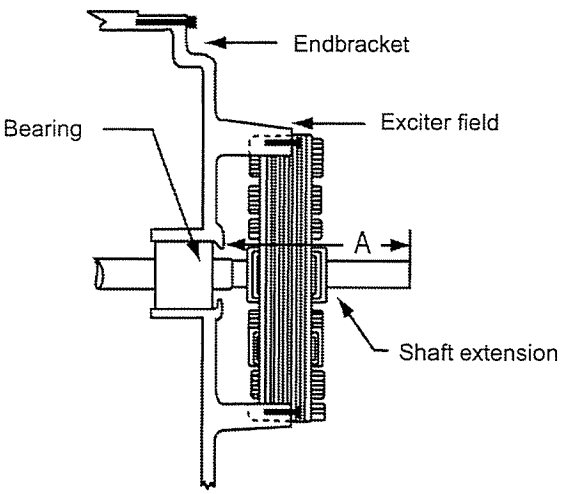

Figure 11: Generator coupling check

Check the engine flywheel housing pilots's radial and face runout by mounting a dial indicator and measuring the flywheel to the flywheel housing as shown in Figure 5. See Table 1 for maximum allowable runout.

Check the engine flywheel's radial and face runout by mounting a dial indicator and measuring the flywheel housing to the flywheel as shown in Figure 6. See Table 2 for maximum allowable runout.

Measure the generator drive plate diameter (dimension S of Figure 12) and flywheel bore diameter (dimension B of Figure 13). Drive plate diameter must not be greater than the flywheel bore diameter. Also check to make sure the hole centers match (dimension W of Figure 12 and dimension C of Figure 13).

Caution: *Never grind the OD of drive discs or attempt to drill out the holes. If the dive discs do not fit properly, use different discs or a different flywheel.*

Measure the axial distance from the surface on the generator adapter to the outside surface on the drive disc coupling plates (dimension Y in Figure 12). This dimension is recorded on the Factory Recorded Dimensions sheet, which was packaged with the generator. If the dimensions do not match, move the rotor axially relative to the stator until the dimensions are equal.

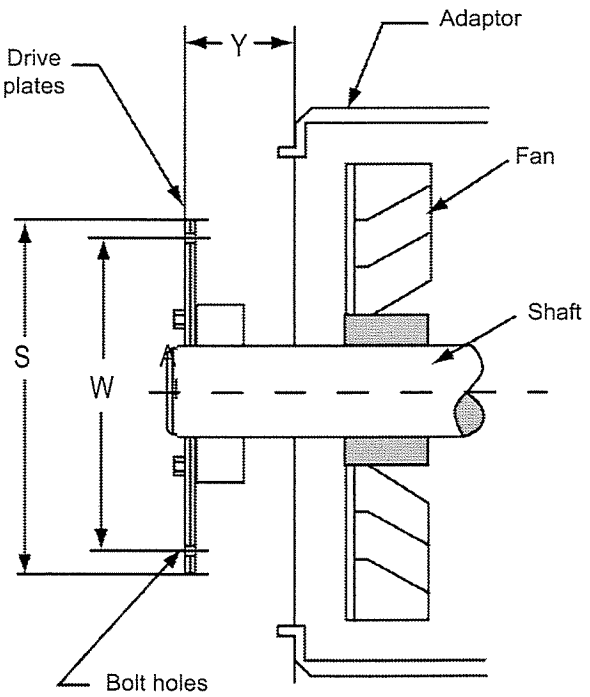

Figure 12: Single bearing generator drive plate and adaptor

Caution: *The number and thickness of drive discs are specified for torque requirements. Do not remove drive discs to compensate for spacing.*

Measure the axial distance from the machined surface on the engine flywheel housing the bottom of the fly wheel drive disc recess (dimension G in Figure 13). Make sure the difference between dimensions Y (of Figure 12) and G are less than 1/32 inch. If G is more than Y, install additional spacers between the drive discs and the generator hub, If Y is more than G, remove spacers between the drive discs and generator hub.

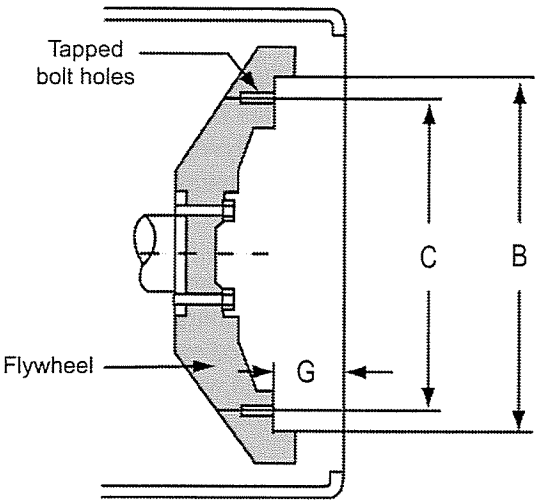

Figure 13: SAE flywheel and adapter

Install the generator to the engine. Make sure the drive discs seat in the recess of the flywheel housing. Secure the generator to the engine (drive discs to flywheel, adapter to flywheel housing), and the base. Use lock washers on all bolts. Torque the adapter and drive discs in a criss-cross pattern to the values in Table 3.

Ensure that the bolts in the flywheel do not bottom out. If they are too long or cannot be tightened with a socket or box wrench, use 1/4 to 3/8-inch long spacers inserted in the bolts as shown in Figure 14 to increase the clearance between the bolt head and the flywheel.

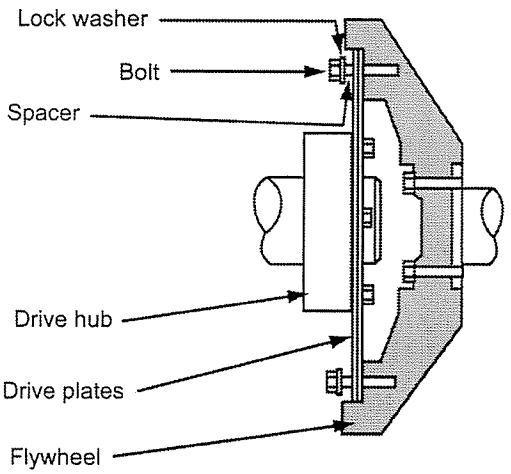

Figure 14: Disc-to-flywheel installation

Occasionally, there is insufficient clearance to install the bolts that fasten the drive discs to the engine flywheel, and the fan will have to be temporarily moved to accommodate this. This situation will typically occur with several types of generators:

- With the three-frame units that have an aluminum fan, loosen the fan hub bolts to move the fan. After installing the drive disc-to-flywheel bolts, move the fan back so the rotor-side edge is flush with the air opening and the minimum distance between the windings and the fan is 3/8 inch. Torque the fan hub bolts to 75 ft-lbs.

- With sheet metal fans with cast hubs that are in turn mounted on the drive hub, mark the drive hub as closes as possible to the fan hub. Loosen the two set screws, the fan clamping bolt, and the fan bolts. Wedge the fan open, and move it out of the way (See Figure 15). After attaching the drive discs-to-fly wheel bolts, align the fan hub to the mark to move the fan back to its original position. Ensure the key is fully in place under the fan hub and positioned so the set screw will press on the key. Tighten the fan hub clamping bolt and the set screws. Install the fan bolts and torque them according to Table 3.

Note: *The generator with sheet metal fans and cast fan hubs is shipped from the factory with the fan 1/2 to 3/4 inch from the fan baffle and clear of the inside adaptor for optimum air flow through the exhaust screen.*

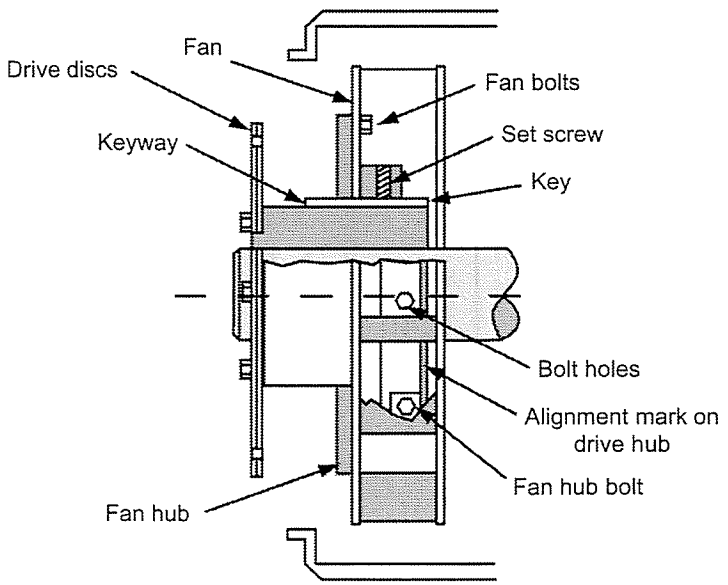

Figure 15: Moving sheet metal fans

After installing the drive disc-to-flywheel bolts, check the runout of the generator shaft by placing the base of a dial indicator on the generator frame and positioning of the probe on the shaft as shown in Figure 16. If the total indicated runout exceeds 0.003 inch, remove the drive discs bolts, and rotate the generator relative to the engine flywheel. Reinstall the bolts, and check the runout again.

Recheck the shaft-end-to-bearing-housing distance (dimension A in Figure 11).

Mount the brushless exciter armature assembly to the generator shaft (as described in the assembly procedures below).

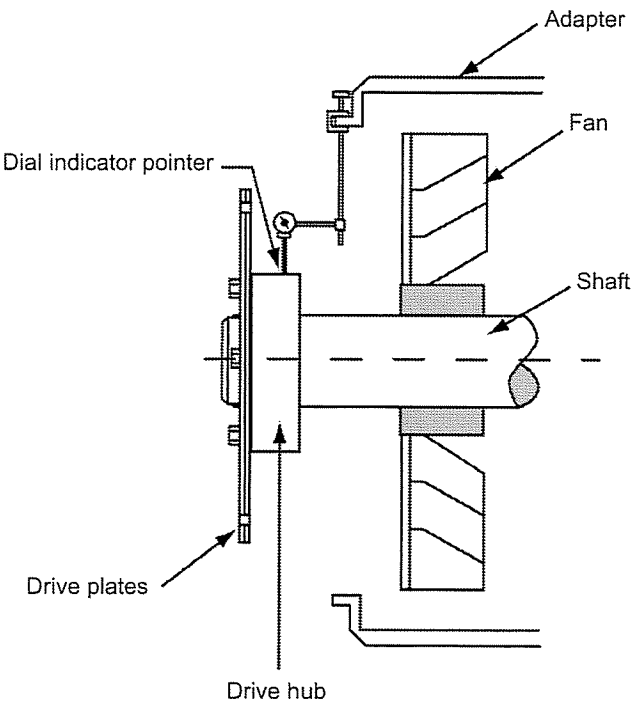

Figure 16 Runout check

Foot deflection

After alignment, check for foot deflection or "soft foot" condition on each shim location to eliminate distortion of the generator frame. Do this by loosing one mounting bolt at a time and checking deflection after retightening. Deflection at the shim location from shims under compression to a loosened condition must not exceed 0.003 inch.

Doweling

In case the mounting bolts loosen during operation, doweling will prevent movement of the generator. Dowel as follows:

Check the alignment after the generator has been in operation for at least 48 hours. If alignment is not satisfactory, realign.

Drill holes through the footpads and into the base in two mounting pads opposite each other. Drill the holes slightly smaller than the dowel pin.

Ream the holes to the proper diameter for the pin. Clean out chips, and install the pins.

Electrical connections

If the generator was subjected to a rapid change in temperature, freezing or wet conditions during shipment or storage, measure the insulation resistance of each winding and dry the generator, if necessary, as described in the maintenance section below.

Make all electrical connections (main load, temperature monitoring device, space heater, AVR) in accordance with local regulations and National/International Electrical Code requirements. Check the electrical diagrams provided with the generator or manual. The main terminals need to be properly spaced for the load connections. Refer to Table 3 for the proper torque values for the connections.

On larger generators grounding points are provided for properly grounding the system to the generator frame. The grounding wire must be of the same size as the generator leads.

Space heaters

When the generator has optional space heaters to prevent water condensation during long standstills, connect the space heaters so they start when the generator is turned off and stop when the generator is switched on. Refer to the electrical diagrams for the space heater characteristics.

Warning: *The space heaters are designed to be energized when the generator is shut down. They are hot enough to cause skin burns. Terminals for power at the space heaters are live during operation. Disconnect power to the space heaters before removing the generator covers.*

Inspection before startup

After electrical connections have been made, perform the following checks:

Check all the connections to the electrical diagrams provided.

Secure all covers and guards.

Caution: *Do not pry on the fan.*

Turn the rotor slowly with the appropriate starting mechanism (bar the engine or flywheel) through one revolution to see if the rotor turns freely.

Check the bearings to see they are properly lubricated.

Determine the direction of the engine rotation, and make sure that it matches the rotation arrows on the generator.

Make sure the power requirements comply with the data on the generator nameplate. Make sure that the engine-generator set is protected with adequate engine governors and against excessive overspeed. Make sure the output of the generator is protected with an overload protection device, such as circuit breakers or fuses, sized in accordance with National Electrical/International Electrical Code and local electrical code standards. Fuses need to be sized using the lowest possible current rating above the full-load current rating (115% of rated current is commonly recommended).

Remove tools and other items from the vicinity of the generator.

Operation

Initial startup: generators with both automatic and manual voltage control

1. Disconnect the generator output from the load. Open the main circuit breaker.

2. Turn the manual voltage adjust rheostat full counterclockwise.

3. Actuate the auto-manual switch to the manual position.

4. Start the prime mover, and bring the set to rated speed. Turn the manual voltage adjust rheostat to reach rated voltage. Close the output circuit breaker, and apply load in steps until the rated load is reached. Adjust the manual adjust rheostat as necessary to obtain the desired output voltage.

5. Gradually reduce the load, and adjust the rheostat accordingly until no load is reached. Open the circuit breaker, and stop the prime mover.

6. Actuate the auto voltage rheostat. Then start the genset, and bring it to rated speed. Adjust the voltage to the desired value.

7. Close the output circuit breaker. Then check the generator voltage and voltage regulation. Apply load in steps until the rated load is reached.

8. Check for vibration levels at no load and rated load. A slight increase is normal. As the load is maintained for 2-3 hours, the vibration levels will gradually increase and reach a final level.

Caution: *Do not actuate the auto-manual switch with the full load applied to the generator. Whenever possible, stop the generator before switching.*

Initial startup: Generators with automatic voltage control only (generator has an automatic voltage regulator (AVR) with no auto-manual switch)

1. Disconnect the generator output from the load by opening the main circuit breaker.

2. Turn the voltage adjust rheostat full counterclockwise. Start the prime mover, and bring the set to rated speed. Turn the voltage adjust rheostat to obtain the desired voltage.

3. Close the output circuit breaker, and apply load in gradual steps until the rated load is reach. Note the voltage regulation with the changes in load steps.

4. Check for vibration levels at no load and rated load. A slight increase is normal. As the load is maintained for 2-3 hours, the vibration levels will gradually increase and reach a final level.

Restoring residual magnetism/field flashing

The direct current necessary to magnetize the generator field (rotor) is obtained from the exciter. Upon starting the generator, current and voltage is induced into the exciter by the magnetic lines of force set up by residual magnetism of the exciter field poles. Residual magnetism of the exciter field poles may be lost or weakened by a momentary reversal of the field connection, a strong neutralizing magnetic field from any source, or non-operation for a long time. If the generator fails to generate voltage after it has come up to rated speed, it may be necessary to restore residual magnetism.

To restore the small amount of residual magnetism necessary to begin the voltage build up, connect a 12 or 24-volt battery to the exciter field coil circuit and flash as follows:

1. Open the output circuit breaker, and stop the engine.
2. Disconnect the exciter field coil wires EF1 at the terminal EF1 and EF2 at the terminal EF2, and connect the battery positive lead to the field coil lead EF1.

Note: *If the polarity of the exciter is reversed by flashing the field, it may be corrected by interchanging the battery leads.*

3. Flash the field by touching the battery lead to the field coil circuit terminal EF2.
4. Disconnect the battery leads.
5. Reconnect the field coil lead EF1 to terminal EF1, and reconnect the field coil lead EF2 to terminal EF2.
6. Start the generator, and check for voltage build up. Reflash if the generator output voltage does not build up, or flash with the generator running, the field coil wires connected to the regulator, and a 3-amp or larger diode off the positive terminal of the battery per Figure 17.

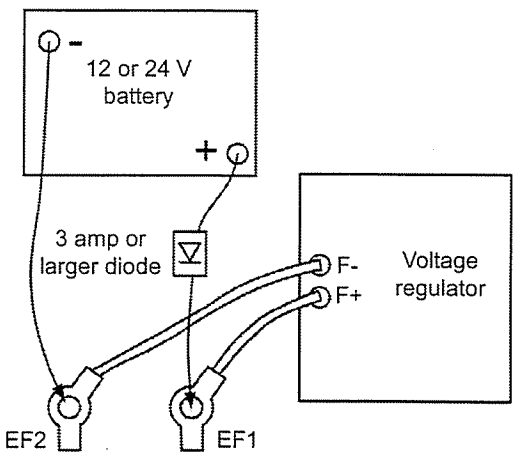

Figure 17: Field flashing setup with the field wires connected to the regulator

Continuous operation

Operate the generator within the nameplate values of kW, power factor, and voltage. If the generator is operated below the rated power factor and voltage, decrease the kVA to prevent overheating of the field and stator windings.

Rotor overheating may occur when the generator is carrying excessive unbalanced loads. Negative sequence currents flowing in the field pole face cause the rotor heating. For a general guide to the allowable phase unbalance, see Figure 18, Guide to allowable phase unbalance (which is based on a 10% equivalent negative sequence current).

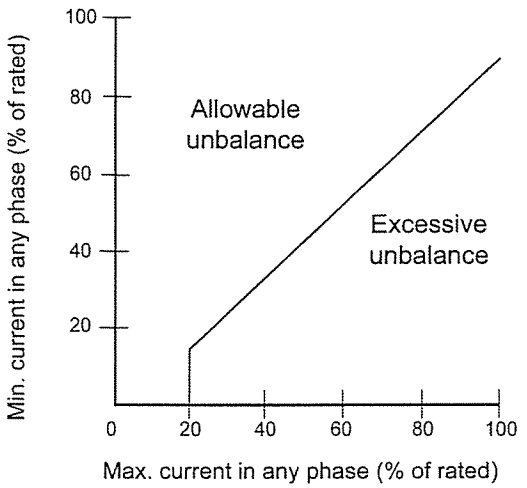

Figure 18: Guide to allowable phase unbalance

The guide is used in the following manner: Find the point where the vertical line (determined by the minimum current in any of the phases and expressed in percent of rated current) crosses the horizontal line (determined by the maximum current in any of the phases and expressed in percent of rated current). Ensure the point where these two lines intersect is within the permissible allowable unbalance region for safe operation of the generator.

Loss of field excitation can result in the unit operating out of synchronization with the system when operating is parallel. This has the effect of producing high currents in the rotor, which will cause damage very quickly. Protective relays should be considered to open the circuit breaker.

Idling

Unless the voltage regulator has V/Hz built in, having the generator set in operating mode while idling the engine can cause permanent equipment damage. If engine adjustments require that the engine be run at idle speed and the regulator does not have V/Hz, make the generator regulating system inoperative during idling by one of the following methods:

When the generator is provided with a voltage shutdown switch, be sure the switch is set to the idle position while the engine is running at idle speed.

Where the generator set is provided with field circuit breakers, set the circuit breaker to the off position while the generator is running at idle speed.

Where the generator set is provided with an automatic/manual control switch that has an off position, switch it to off while the engine is running at idle speed.

Where the generator set does not have any of the above options, remove the wires from the voltage regulator input power terminals when the engine is running at less than rated speed.

Caution: *Do not make connections or otherwise make contact with the generator leads or other devices connected to them unless the genset is stopped and the phase leads are grounded.*

Parallel operation

For the generator to operate in parallel with a system in operation, the phase sequence of the generator must be the same as that of the system. Use transformer to reduce the voltage to an acceptable level, and then use a phase rotation meter or incandescent lamp method, described in electrical machinery handbooks, for a phase sequence check.

The output voltage at the paralleling point must be the same as each instant, which requires that the two voltages be of the same frequency, same magnitude, same rotation, and in coincidence with each other.

Voltmeters indicate whether the voltage magnitude is the same, and frequency meters indicate whether the frequencies are the same. Whether the voltages are in phase and exactly at the same frequency is indicated by a synchroscope or by synchronizing lamps.

A synchroscope can be used to indicate the difference in phase angle between the incoming machine and the system. The generator can be paralleled by using incandescent lamps connected as shown in Figure 19. The voltage rating of the series lamps must equal the voltage rating of the transformer-low voltage winding.

Each prime mover in the system must have the same speed regulating characteristics, and the governors must be adjusted to give the same speed regulation by as determined by applying load that is proportional to the full load rating of the generator.

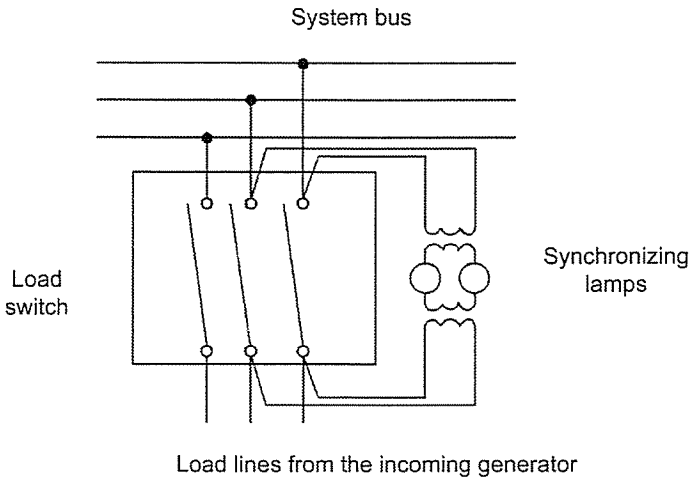

Figure 19: Synchronizing paralleled generators with test lamps

The voltage regulator must include paralleling circuitry.

If cross-current compensation is used, paralleling current transformers must give the same secondary current.

Current transformer secondary windings provide reactive kVA droop signal to the voltage regulator. Accidental reversal of this electrical wiring will cause the voltage to attempt to rise with load rather than droop. If this occurs during paralleling, stop the unit and reverse the wires at the voltage regulator terminals.

If the set is provided with a unit/parallel switch, set the switch to the parallel position on the unit being synchronized.

Synchronize the generator by adjusting the speed (frequency) slightly higher than the system. Observe the synchroscope or the lamps. The lamps should fluctuate from bright to dark at the rate of one cycle every 2 to 3 seconds. When the generator is in phase (the lights will be dark), close the circuit breaker. Immediately after closing the breaker, measure the line current kVAR of the generator. The readings must be within the rating of the unit. A high ammeter reading accompanied by a large kW reading indicates faulty governor control. A high ammeter reading accompanied by a large kVAR unbalance indicates problems with the voltage regulator. Adjusting the cross current or voltage droop rheostat should improve the sharing of kVAR.

To shut down the generator operating in parallel, gradually reduce the kW load by using the governor to reduce speed. When kW load and line current approach 0, open the generator circuit breaker. Operate the generator unloaded for several minutes to dissipate the heat in the windings. Refer to the prime mover manual for shutdown and cool-down procedures.

Maintenance

Warning: *Do not service the generator or other electrical machinery without de-energizing and tagging the circuit as out of service. Dangerous voltages are present, which could cause serious or fatal shock.*

Schedules

A regular preventive maintenance schedule will ensure peak performance, minimize breakdowns and maximize generator life. The schedule listed below is a guide for operating under standard conditions. Specific operating conditions may require reduced or increased maintenance intervals. Also, if there is a different or more specific schedule for your generator than the schedule provided below, it will be included as a supplement to the manual package.

Every day

Visually check generator bearing housings for any sign of oil seepage.

Check the operating temperatures of the generator stator windings.

Check the control panel voltmeter for proper stability and voltage output.

Monitor the power factor and generator loading during normal operation.

With generators that have sleeve oil bearings, check the operating temperatures and sight glass levels (if applicable).

Every week

Visually inspect the bearing exterior for dirt, and clean if necessary.

Inspect any generator air filters for build up of contaminants, and clean or replace as required

Every 2000 Hours or 6 months of operation

Remove generator outlet box cover. Visually inspect the stator output leads and insulation for cracking or damage. Check all exposed electrical connections for tightness. Check transformers, fuses, capacitors, and lightning arrestors for loose mounting or physical damage. Check all lead wires and electrical connections for proper clearance and spacing.

Clean the inside of the outlet box, air screens, bearing housings, and air baffles with compressed air and electrical solvent.

With generators that have ball or roller bearings, check machine vibrations and bearing condition with a spectrum analyzer or shock pulse.

Regrease the regreaseable-type bearings. With generators that have sleeve oil bearings, inspect bearing oil for proper levels and clarity.

Every 8000 hours or 1 year of operation
Check insulation resistance to ground on all generator windings, including the main rotating assembly, the main stator assembly, the exciter field and armature assemblies, and the optional PMG assembly.

Check the space heaters for proper operation.

Check the rotating rectifier connection tightness.

With generators that have sleeve oil bearings, replace the bearing oil.

Every 20,000 hours or 3 years of operation
With generators that have sleeve oil bearings, perform a sleeve bearing inspection to include the removal of the upper bearing housing and bearing liner to inspect the liner, shaft journal, and seal surfaces for wear or scoring.

Remove the endbrackets, and visually inspect the generator end windings for oil or dirt contamination. Excessive contamination may necessitate surface cleaning with compressed air and electrical solvent.

Inspect the fan and fan hub for damage.

Every 30,000 hours or 5 years of operation
(Contact Kato Engineering for assistance)

Disassemble the generator (this includes rotor removal).

Clean the generator windings using either (depending upon the severity of contamination) 1) compressed air and electrical solvent or 2) de-greaser and high pressure hot water wash. Dry the windings to acceptable resistance levels (see the dry out procedure).

Inspect the rotor shaft bearing journals for wear or scoring.

With generators that have ball or roller bearings, replace the bearings.

With generators that have sleeve bearings, replace the bearing liners and oil seals.

Maintenance procedures

Visual inspection methods of windings

Electric machines and their insulation systems are subjected to mechanical, electrical, thermal and environmental stresses that give rise to many deteriorating influences. The most significant of these are the following:

Thermal aging: This is the normal service temperature deteriorating influence on insulation.

Over temperature: This is the unusually high temperature of operation caused by conditions such as overload, high ambient temperature, restricted ventilation, foreign materials deposited on windings, and winding faults.

Overvoltage: This is an abnormal voltage higher than the normal service voltage, such as caused by switching or lightning surges or non-linear loads. Operating above rated nameplate voltage will reduce insulation life.

Contamination: This deteriorates electrical insulation by 1) conducting current over insulated surfaces 2) by attacking the material to reduce electrical insulation quality or physical strength, or by 3) thermally insulating the material so the generator operates at higher than normal temperatures. Such contaminants include water or extreme humidity, oil or grease including unstable anti-wear and extreme pressure lubricants, conducting and non-conducting dusts and particles, industrial chemicals such as acids, solvents, and cleaning solutions.

Physical damage: This contributes to electrical insulation failure by opening leakage paths through the insulation. Physical damages can be caused by physical shock, vibration, over-speed, short-circuit forces or line starting, out-of-phase paralleling, erosion by foreign matter, damage by foreign objects and thermal cycling.

Ionization effects: Ionization (corona), which may occur at higher operating voltages, is accompanied by several undesirable effects such as chemical action, heating, and erosion.

To achieve maximum effectiveness, a direct a visual inspection program initially to those areas that are prone to damage or degradation caused by the influences listed below. The most suspect areas for deterioration or damage are 1) ground insulation, which is insulation intended to isolate the current carrying components from the non-current bearing components, and 2) support insulation: which includes blocks and slot wedges and are usually made from compressed laminates of fibrous materials, polyester, or similar felt pads impregnated with various types of bonding agents.

Deterioration or degradation of insulation from thermal aging: Examination of coils reveal general puffiness, swelling into ventilation ducts, or a lack of firmness of the insulation, suggesting a loss of bond with consequent separation of the insulation layers from themselves or from the winding conductors or turns.

Abrasion: Abrasion or contamination from other sources, such as chemicals and abrasive or conducting substances, may damage coil and connection surfaces.

Cracking: Cracking or abrasion of insulation may result from prolonged or abnormal mechanical stress. In stator windings, looseness of the bracing structure is a certain sign of such phenomena and can itself cause further mechanical or electrical damage if allowed to go unchecked.

Erosion: Foreign substances impinging against coil insulation surfaces may cause erosion.

Cleaning

Exterior: Wipe loose dirt from the exterior with a clean, lint-free cloth. Remove stubborn accumulations of dirt with a detergent or solvent that won't damage the paint or metal surfaces. Use a vacuum to clean ventilating ports.

Warning: *When using cleaning solvents, ensure adequate ventilation and user protection.*

Windings, assembled machines: Where cleaning is required at the installation site and complete disassembly of the machine is unnecessary or not feasible, pick up dry dirt, dust or carbon with a vacuum cleaner to prevent the redistribution of the contaminant. A small non-conducting nozzle or tube connected to the vacuum cleaner may be required to reach dusty surfaces or to enter into narrow openings. After most of the dust has been removed, a small brush can be affixed to the vacuum nozzle to loosen and allow removal of dirt that is more firmly attached.

After the initial cleaning with a vacuum, compressed air may be used to remove the remaining dust and dirt. Compressed air used for cleaning must be clean and free of moisture or oil. Air pressure or velocity must be adequately controlled to prevent mechanical damage to the insulation. Disassembly of the machine and more effective cleaning by a qualified Kato technician may be required if the above described field service cleaning procedures do not yield effective results.

Windings, disassembled machines: Take an initial insulation resistance reading on the machine to check electrical integrity. The high pressure hot water wash method of cleaning, which sprays a high velocity jet of hot water and water containing a mild detergent, is normally effective in cleaning windings, including those subjected to flooding or salt contamination. Use multiple sprays with clean water to remove or dilute the detergent following the detergent spray. Dry the machine until normal insulation resistance values are obtained at room temperature. Solvents,

such as naphtha, are effective for removing oil or grease and may be required if water or detergent is not adequate.

Electrical contacts: Clean electrical contacts, switch contacts and terminals with an approved contact cleaner. Do not file contacts.

Insulation resistance tests at low voltage

Insulation tests are conducted for two reasons: to discern existing weakness or faults or to give some indication of expected service reliability.

Caution: *The insulation resistance tests are usually made on all or parts of an armature or field circuit to ground. They primarily indicate the degree of contamination of the insulating surfaces or solid insulation by moisture and other conducting influences and will not usually reveal complete or uncontaminated ruptures.*

Insulation resistance tests are based on determining the current through the insulation and across the surface when a direct voltage is applied. The current is dependent upon the voltage and time of application, the area and thickness of the insulation, and the temperature and humidity conditions during the test.

Note: *The insulation resistance value increases with decreasing winding temperatures. All readings must be corrected to winding temperatures. Use Table 4 for converting megger readings to other temperatures (e.g., 100 megohms at 50° C is converted to 170 megohms: 1.7 x 100).*

The insulation resistance test is used to determine the insulation condition prior to application of more extensive testing measures. Refer to the following electrical measurement procedures for testing detail. Contact Kato Engineering or refer to IEEE Standard. 432-1992 when more extensive insulation tests are required.

Winding Temp (°C)	Conversion factor
10	0.23
20	0.37
30	0.6
40	1
50	1.7
60	2.7
70	4.5
80	7.5
90	14
100	23
110	38
120	61

Table 4: Temperature Conversion Factor for Resistance Readings

Exciter field (stator) and PMG armature (stator)

1. Disconnect the exciter leads from the terminals in the terminal box.
2. Connect exciter leads to one clamp of 500-volt megger, and connect the other clamp to the generator frame.
3. Apply 500 volts from the megger, and measure the resistance reading after 1 minute. The reading must be a minimum of 1 megohm. If it is not, refer to the dry out procedures.
4. Ground the exciter field leads to the generator frame for several minutes after the megger has been disconnected. This will allow the voltage build up to be properly discharged.

Exciter armature

1. Disconnect the exciter armature leads from the rotating rectifiers.

2. Connect the leads of exciter armature to one clamp of a 500-volt megger, and connect the other clamp to suitable connection on the shaft.

Warning: *Never apply the megger to the rotating rectifier.*

3. Apply 500 volts from the megger, and measure the resistance reading after 1 minute. The reading must be a minimum of 1 megohm. If it is not, refer to the dry out procedures.

4. Ground the exciter leads to the shaft after disconnecting the megger. This will allow the voltage build up to be properly discharged.

Main rotor

1. Disconnect the generator field leads from the positive and negative terminals of the rotating rectifier.

2. Connect the positive and negative leads to one clamp of the 500-volt megger, and connect the other clamp to the shaft.

3. Apply 500 volts from the megger, and measure the resistance reading after 1 minute. The reading must be a minimum of 1 megohm. If it is not, refer to the dry out procedures.

4. Ground the field leads to the shaft after disconnecting the megger. This will allow the voltage build up to be properly discharged.

Main stator

1. Disconnect power connections and all control apparatus from the generator terminals.

2. Measure insulation resistance of each phase separately with the two other phases shorted to the frame.

3. Use a 500-volt megger connected between the lead(s) of the phase to be measured and generator frame. The minimum 1-minute insulation resistance must not be less than that given by the following formula:

$$\text{Resistance in megohms} = \frac{\text{Rated generator voltage}}{1000} + 1000$$

   If it is less than above, refer to dry out procedures.

4. Ground the leads to the frame after the 1-minute megger test. This will allow the voltage build up to be properly discharged.

Caution: *Do not apply heat too rapidly. It could damage the windings.*

Dry out procedures

If the insulation resistance readings are below the recommended minimum values specified previously, use one of the dry out procedures described below. Select the procedure based on the size and location of the unit, available equipment, and experience of personnel. Before drying, remove the voltage regulator, and cover all inlet and discharge openings. Provide an opening at the top of the machine, preferably at the fan end, for moisture to evaporate.

Drying with external heat: Place heat lamps, space heaters (in addition to the ones already supplied) or a steam pipe near the windings. Monitor winding temperatures. Raise winding temperature gradually at a rate of 50° F (10° C) per hour up to 200° F (93° C). Measure insulation resistance at 1-hour intervals. Typically the insulation resistance will slowly drop while the temperature is coming up, and then gradually increase and level out.

Drying with ac current in the armature: Short circuit the generator terminals. Provide dc excitation to the brushless exciter field winding. Insert a current transformer and an ammeter to read full load current. Run the generator at rated speed. Apply excitation to the exciter field until rated current is developed. Monitor winding temperatures until they stabilize. Continue running until insulation resistance values level off. Monitor winding temperatures. Raise winding temperature gradually at a rate of 50° F (10° C) per hour up to 200° F (93° C). Measure insulation resistance at 1-hour intervals. Typically, the insulation resistance will slowly drop while the temperature is coming up and then gradually increase and level out.

Bearing lubrication

Shielded or sealed ball bearings: Shielded or sealed ball bearings are factory packed with lubricants and generally can be operated several years without requiring replenishment or change of the grease. If repacking the grease is necessary, disassemble the machine, clean the bearings, and repack the bearings about 1/2 full using a high quality ball bearing grease, which must be capable of lubricating satisfactorily over a temperature range of the lowest ambient temperature to 250° F.

Regreaseable ball or roller bearings: In applications where regreaseable bearings are used, grease fill fittings and relief vales are incorporated into the bearing housing. Lubricate the bearings in accordance with the lubricating instructions attached to the generator.

Sleeve bearings: Lubricate the bearings in accordance with the lubricating instructions attached to the generator and the bearing lubrication instructions, which are provided in the manual package as supplementary material.

Rectifier tests

If a failure of a rectifier is suspected, remove the exciter cover. Remove the nut and washer holding the rectifier in the heat sink, and remove the diode lead wire. Lift the rectifier from the heat sink (see figure 20 for an overview). Test the entire rectifier with an ohmmeter or test lamp as follows:

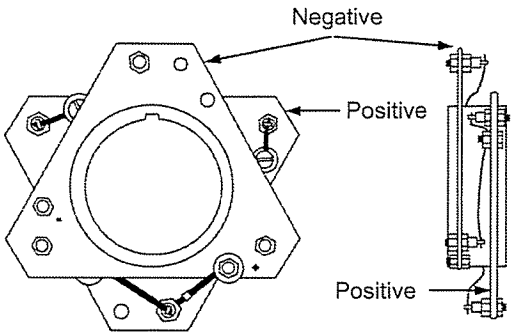

Figure 20: Rectifier

Ohmmeter: Connect the ohmmeter leads across the rectifier in one direction (see Figure 21). Note the meter reading. Reverse the leads, and note the meter reading. The meter should indicate a low resistance when the leads are across the rectifier in one direction and a high resistance when the leads are across the rectifier in the opposite direction. A low resistance in both directions indicates a short. A high resistance in both directions indicates an open rectifier.

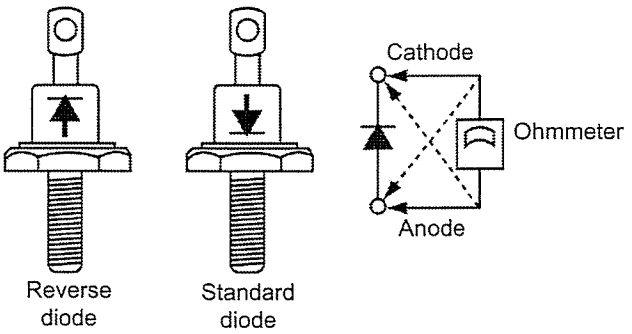

Figure 21: Testing the rotating rectifier with an ohmmeter

Test lamp: Connect the leads of a test lamp, consisting of standard flashlight batteries and a flashlight and built, as shown in Figure 22, across the rectifier in one direction. Then reverse the leads. The light should light in one direction but not the other. If the light lights in both directions, the rectifier is shorted. If the light does not light in either direction, the rectifier is open.

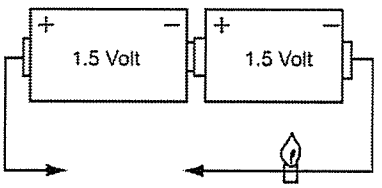

Figure 22 Test lamp

Replace defective rectifiers with rectifiers of the same operating characteristics as rectifiers installed in the generator at the factory. Order rectifiers by part number, including the model and type of exciter as well as the generator serial number.

Surge protectors may be included on the rectifier. Disconnect one lead of the surge protector, and connect the leads of a test lamp, consisting of standard flashlight batteries and a flashlight and built as shown in Figure 21, across the surge protector in either direction.. If the light comes on, the surge protector is defective. Order surge protectors by part number, including the model and type of exciter as well as the generator serial number. Following replacement, make sure that the field lead tie-down lacing is securely wound on the shaft and tied tightly.

Disassembly

Note: *The following procedures are meant to be a general guide. Procedures for your unit may vary.*

Warning: *Ensure the generator has stopped and is de-energized before disassembly.*

Warning: *Use a hoist and slings or chains to support components during removal. Be extremely careful not to damage components.*

Overall disassembly

1. Remove the terminal box cover, and disconnect the load leads and exciter field leads. Tag the leads to ensure they are correctly connected when the generator is reassembled.

2. Remove the bolts securing the generator feet to the base, and move the generator to an area that allows sufficient room for disassembly.

3. Remove the coupling or drive plates.

4. Remove the exciter cover.

5. Remove the clips securing the exciter field leads to the exciter frame and endbracket. Disconnect the leads and remove the exciter frame/ stator and/or exciter-PMG frame/stator.

6. Remove the (optional) PMG and exciter armature as described below.

7. Support the shaft. Remove the exciter-end endbracket bolts, and remove the endbracket. Tap lightly with a rubber or fiber mallet to loosen the endbracket if necessary. Repeat with the drive-end endbracket (if applicable).

8. Remove the fan from the hub where applicable. If necessary, make sure to mark the location of the fan for reinstallation.

9. Float out the rotor (see Figure 23). First attach a pipe over the shaft on the drive end. Attach slings around the pipe on one end and around the shaft on the opposite end. Lift up the rotor, and move it out, resting the rotor as the slings are moved down the pipe for the next lifting stage.

Warning: *Make sure the pipe is strong enough to support the weight of the rotor and that it does not have rough edges on the inside, which could damage the shaft.*

Caution: *To prevent tension on the shaft, put the slings around the largest shaft step possible.*

Caution: *Make sure the rotor does not rest on the stator during the stages of movement. Make sure the rotor does not hit the stator.*

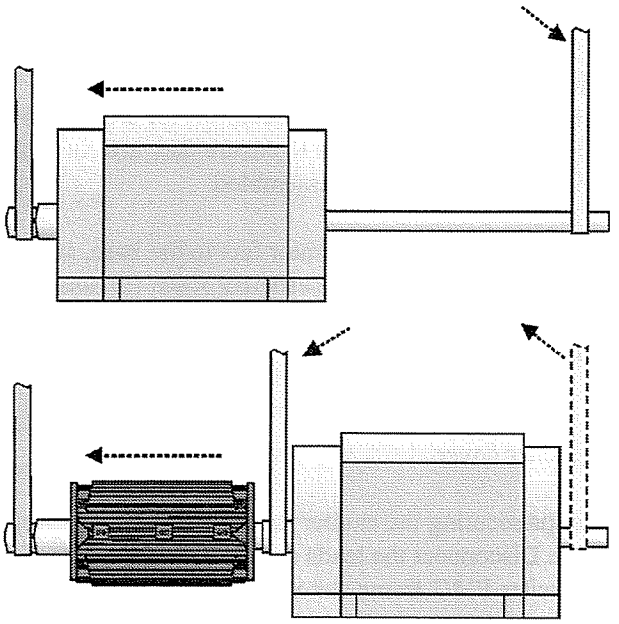

Figure 23: Floating the rotor

Caution: *Ensure the generator field wires are flat in the wireway so they don't tear during pulling. Do not pull on the edges of the heat sinks or on the exciter armature windings.*

Warning: *Pull the PMG off straightly. The assembly may pull toward other steel components. Be careful that your fingers or hands do not get pinched.*

Exciter armature and PMG removal (see Figure 24)

1. Remove the exciter cover.
2. Remove the retaining bolt and washer.
3. Disconnect the field wires on the rotating rectifier.
4. If the generator has a PMG, pull it off separately using hand force. Wrap the PMG rotor in plastic to avoid contamination with metal filings.
5. Slowly pull the armature assembly off of the generator shaft. If the exciter can not be pulled off by hand, use a hydraulic jack as shown in Figure 25.
6. Remove the key from the keyway in the generator shaft.

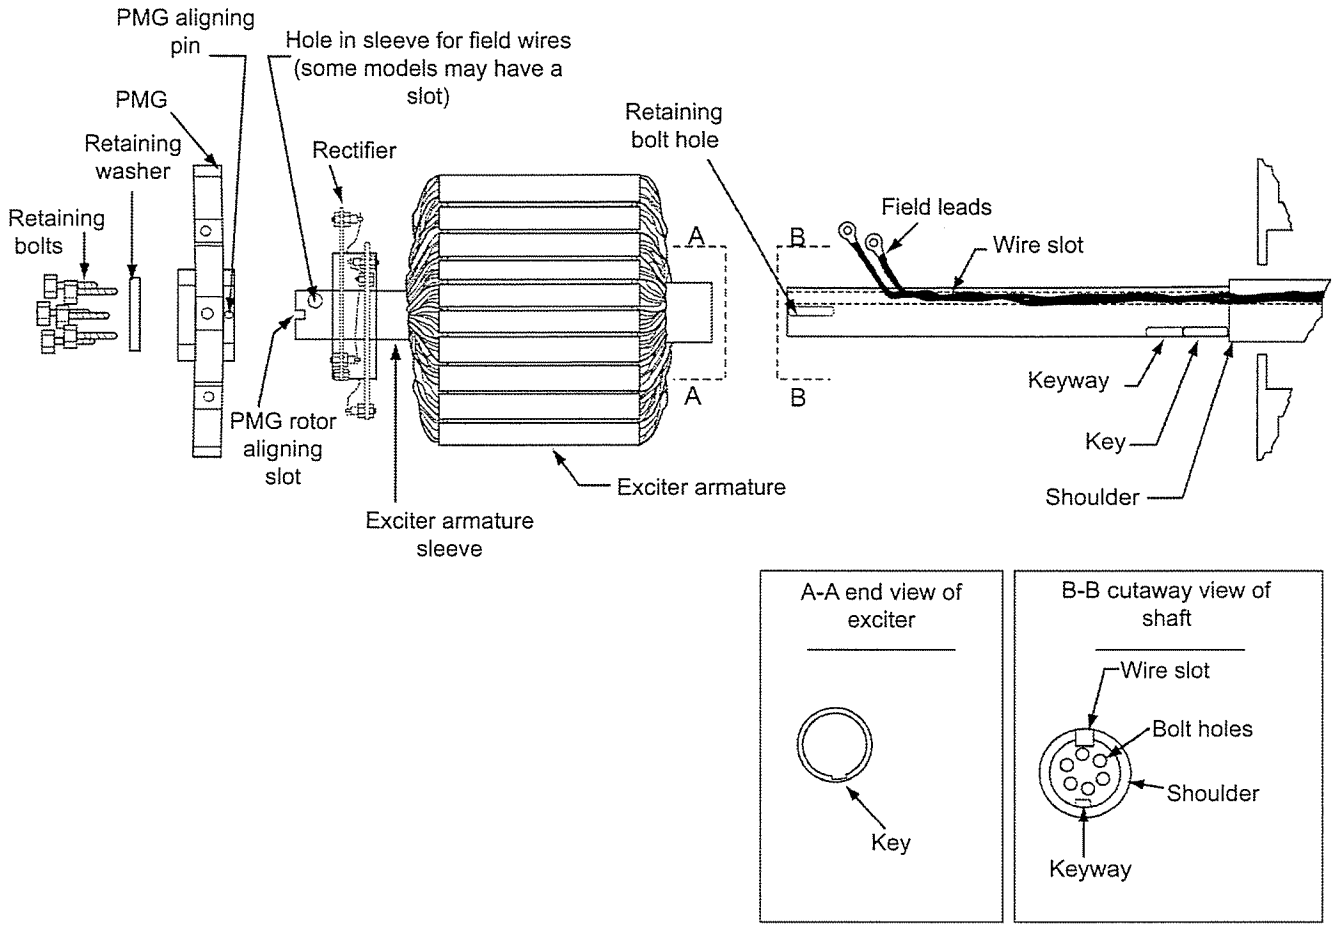

Figure 24: Exciter armature assembly

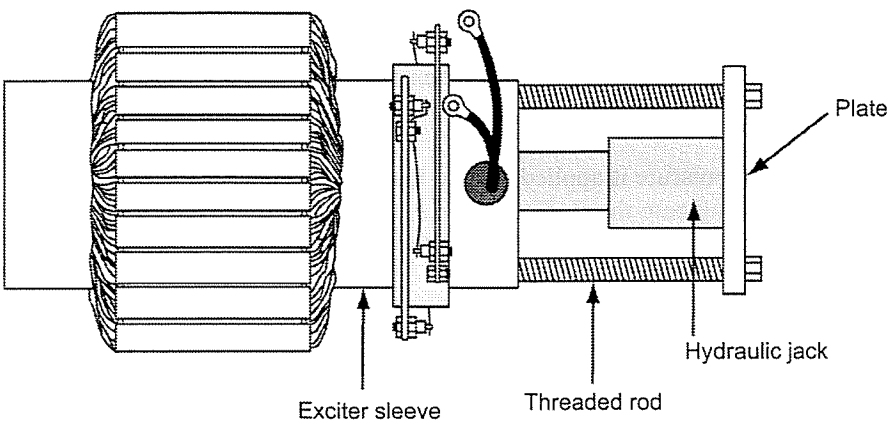

Figure 25: Pulling the armature assembly

Bearing removal

1. Remove the endbracket(s) to expose the bearing(s).

2. Use a puller to remove the bearing from the shaft end with a cap. If the bearing is going to be used again, make sure the puller supplies pressure only against the bearing inner ring (see Figure 26).

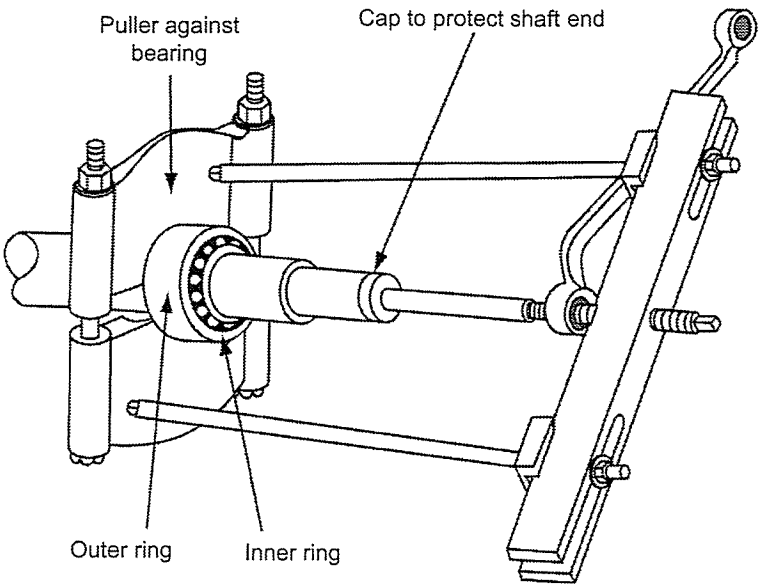

Figure 26: Pulling the bearing

Caution: *Make sure all components are clean before assembly.*

Torque fasteners to the values specified in Table 3 unless otherwise specified.

Assembly

Bearing installation (done prior to installing the rotor)

1. Heat the bearing to 220° - 250° F in a clean oven or with an induction heater.

2. Start the heated bearing on the shaft. Then use a fiber or soft metal tube to tap the bearing into place.

3. Ensuring that pressure is applied only to the bearing inner ring, press the bearing onto the shaft until the inner ring seats against the bearing shoulder on the shaft. Assemble the rest of the generator after the bearing has cooled.

Overall assembly

1. Float in the rotor until the rotor and stator laminations line up. Position the rotor such that a full pole face is at the bottom.

2. Install the endbrackets. Support the rotor during installation. Put Nox-Rust on the bare mating surfaces to prevent rust.

3. Install the exciter armature and optional PMG as described below.

4. Install the covers.

5. Install the coupling or drive plates.

5. Reconnect the load leads and exciter leads.

Exciter armature and PMG installation (see Figure 24)

1. Clean the shaft and inside of the exciter sleeve.

2. Place the key in the slot in the shaft.

3. Lay the generator field wires flat in the wireway with the wire ends protruding past the end of the shaft.

4. Position the exciter armature assembly in line with the shaft, and turn the assembly to the position where the keyway in the exciter sleeve is in line with the key in the generator shaft.

5. With hand force, push the exciter armature assembly over the shaft, so the end of the sleeve is against the shoulder on the shaft. When it is part of the way onto the shaft, start the field lead wires through the wire hole or slot in the exciter sleeve. It may be necessary to tap lightly on the exciter sleeve in order to move the assembly over the key. Use a fiber or rubber mallet. If installation is still a problem, use a heat gun to expand the exciter sleeve.

Caution: *Do not pound on the rectifier or armature windings.*

6. Connect the exciter armature wires to the rectifier terminals.

7. If the generator has a PMG, place it onto the end of the exciter sleeve. Make sure it is aligned with the pin slot in the end of the exciter sleeve.

8. Install the retaining washer and bolt, and torque (60 ft-lbs for a 1/2-inch diameter bolt; 200 ft-lbs for a 3/4-inch diameter bolt).

9. Install the exciter frame/stator and/or exciter-PMG frame/stator. Install the clips securing the exciter field leads to the exciter frame and endbracket and connect the leads.

Note: *To measure air gap, measure completely around the gap between the exciter armature and exciter field with a feeler gauge. Keep the gauge at the tightest point, and turn the generator over to measure the air gap as the rotor turns.*

Caution: *Do not pry on the fan.*

10. Measure the air gap between the exciter armature and exciter field and between the PMG rotor and PMG stator. If the air gap of the armature is less than specified in Table 5 or if the air gap of the PMG is less than 0.020 inch, check 1) generator-engine alignment, 2) check for bearing wear, 3) check for misalignment of the armature, PMG or stator.

Exciter armature diameter (in.)	Minimum air gap (in.)
5 3/4	0.014
9 7/8	0.014
12 1/2	0.018
16 1/4	0.035

Table 5: Exciter air gap

11. Install the exciter cover.

Storage

If the generator is not installed in its operating location as soon as received, store it in a clean, dry area, not subject to vibrations or sudden temperature or humidity changes. Make sure the storage area temperature is between 10° F and 120° F and the relative humidity is less than 60%. If possible, storage should be in an ambient temperature of approximately normal room temperature. Protect the shaft from corrosion by applying an anti-corrosion agent. Cover the unit with a durable cover

Prepare units that cannot be stored in a temperature and humidity controlled area as follows:

Install desiccant bags in the exciter cover and inside the end bells.

Vacuum seal the unit in a covering of plastic or other material designed for that purpose.

Adequately tag the generator to ensure that preservative greases and desiccant bags are removed before the unit is placed in operation.

Warning: *If necessary, remove the covers around the space heaters to ensure against fire.*

If space heaters are supplied, energize them to keep condensation from the windings.

Caution: *Grease used in ball and roller bearing generators is subject to time deterioration. Before placing the unit into service after long-term storage, check the bearings for corrosion, and replace the grease.*

For storage longer than 2 months, rotate the shaft a minimum of 10 revolutions every 60 days.

Troubleshooting (corrective maintenance)

Between regular preventive maintenance inspections, be alert for any signs of trouble. Correct any trouble immediately. See Table 6 for symptoms, causes and remedies.

Warning: *Problems left uncorrected can result in injury or serious damage, which can result in costly repairs and downtime.*

Symptom	Cause	Remedy
No Voltage	Open circuit breaker or fuses (if voltage is sampled on the load side of fuses or circuit breaker)	Check. Reset the circuit breaker or replace fuses if open.
	Overvoltage, undervoltage, or overload devices tripped (when protective devices are incorporated into the circuit)	Check for the cause of the abnormal condition. Correct any deficiencies. Reset devices. Check the generator nameplate for nominal operating values.
	Open circuit in exciter field	Check continuity of shunt field and leads to voltage control. (Use ohmmeter or wheatstone bridge) If open in field coils, remove exciter field assembly and return assembly to factory for repair.
	Loss of residual magnetism in exciter field poles	Restore residual magnetism or flash field. When the voltage regulator is a model that requires flashing, install an automatic field flashing system.
	Open circuit in stator windings	Check for continuity in the windings. Return the generator to the factory for repair if open.
	Malfunction of automatic voltage regulator	See troubleshooting of voltage regulator. Correct deficiencies.
	Short-circuited generator output leads	Clear lead to restore voltage buildup.
	Open in rotating rectifiers	Check rotating rectifiers, and replace if open.
	Open in generator field	Check for continuity and return rotor to factory for repair if field coils are open.
	Shorted or grounded surge protector	Check for shorts or grounds. Replace .
	Shorted or grounded rotating rectifier	Check for shorts grounds. Replace or repair.
	Shorted or grounded exciter armature	Check for shorts or grounds. Replace or repair.
Low voltage	Shorted leads between the exciter armature and generator field	Test and repair.

Low voltage (cont.)	Improper adjustment of voltage adjust rheostat	Adjust rheostat.
	Excessive load	Reduce load. With three-wire, single-phase and four-wire, three-phase generators, the load on each leg must be as evenly balanced as possible and must not exceed the rated current on any leg.
	Line loss	Increase the size of the line wire.
	High resistance connections (hot)	Make better connections.
	Shorted main or exciter field	Test the field coils for possible short by checking resistance with an ohmmeter or resistance bridge. Return the rotor assembly to the factory for repair if field coils are shorted.
	Low power factor	Reduce inductive (motor) load. Some ac motors draw approximately the same current regardless of load. Do not use motors of larger horsepower rating than is necessary to carry the mechanical load.
	Weak field due to operating in a warm temperature	Improve the ventilation of the generator. Field current can be increased providing the generator temperature rating stamped on the nameplate is not exceeded.
	Defective rectifiers in rectifier assembly (stationary)	Check rectifier assembly. Replace defective fuses or rectifiers.
	Excessive load	Reduce load to rated value.
	Defective bearing	Replace the bearing.
	Improper speed of engine driven generator set due to defective governor, ignition system, or carburetor	Check and correct deficiencies.
	Voltage regulator not operating properly	Check the regulator. Adjust, repair or replace.
Fluctuating voltage	Prime mover speed fluctuating	Check frequency and voltage of incoming power when the generator set is motor driven. Check engine governor on engine-driven generator sets.
	Loose internal or load connections	Tighten all connections.
	Generator overloaded	Reduce load to rated value.
	dc excitation voltage fluctuating	Trace dc excitation circuit. Correct any defects.
	Overspeed	Correct speed of prime mover.
High voltage	Improper adjustment of voltage adjust rheostat or voltage regulator	Adjust rheostat and/or voltage regulator.

Overheating	Clogged ventilating screens and air passages	Clean all screens and air passages.
	Dry or defective bearings	Replace defective bearings.
	Coupling misaligned	Align the generator set.
	Generator field coils shorted or grounded	Test field coils for shorts. Replace shorted rotor or return it to the factory for repair.
	Unbalanced load or overload, low PF	Adjust load to nameplate rating.
Vibrations	Defective or dry bearings	Replace defective bearings.
	Misalignment of generator and prime mover	Align the generator set.
	Generator not properly mounted	Check mounting. Correct defective mounting.
	Transfer of vibration from another source	Isolate the generator set from the source of vibration by installing vibration dampeners between generator set base and foundation.

Table 6: Troubleshooting

Appendices

List of equipment required for installation and maintenance:

Test equipment	Notes
Ammeter	Clamp-on, 0 to 500 amp range for measuring of electrical current.
Multimeter	Digital, for measuring voltage, current, frequency and resistance.
Thermometer	For measuring temperature in Celsius
Megger	To measure insulation resistance.
Resistive Bridge	To measure resistance of windings.
Special tools	
Bearing puller	For changing bearing.
Exciter puller	For pulling exciter armature
Standard tools	
Cable tool	Crimping
Flashlight	As required
Grease gun	For lubricating bearings
Hammer	Soft-faced
Lamp (incandescent)	Safety light
Screwdrivers	Standard, sized as required
Screwdrivers	Phillips, sized as required
Wrench	Adjustable, 12-inch
Wrench	Torque 0 to 100 ft-lb
Wrench set	Allen, 1/8 to 1/2 inch
Wrench set	Socket, 1/4 to 1 Inch with 3/8 and 1/2 inch drive
Wrench set	Standard, open-end/box-end combination sized 1/4 to 1 inch
Vacuum	Electric with nonmetallic nozzle
Materials	
Air	Compressed, dry.
Corrosion inhibitor	Nox-Rust VC #10 Oil or equivalent
Covering material	Waterproof desiccant bags for protection from moisture during long-term equipment storage
Detergent	As required for cleaning
Gloves	Chemical-protective
Gloves	Electrical-protective
Heaters	Space Heater, for eliminating excess moisture in damp areas and dry out of motor or generator windings
Plastic	Protection for long-term storage
Rags	As required for cleaning
Water	Warm and clean, for cleaning

Safety Summary

WARNING

This equipment contains high speed (1800 RPM) rotating parts and develops lethal voltage (480 VAC or higher). Stop generator set before removing protective covers for the purpose of making electrical connections, installation, adjustments, inspection, troubleshooting, testing, repair, or parts replacement. Install protective covers before starting the generator set. Failure to observe this precaution can result in serious injury or electrocution.

WARNING

Where meters or test instruments are used for purpose of troubleshooting and testing, it is recommended the test equipment be placed external to the generator and the generator set be stopped while making or removing meter and instrument connections. Be sure protective covers are installed before running unit. Failure to observe this precaution can result in serious injury or electrocution.

WARNING

Do not lift complete generator set by means of lifting eye on generator. Disregarding these instructions may result in serious injury or equipment damage.

WARNING

Do not lift or pry on generator fan. Failure to observe this precaution can result in serious injury and equipment damage.

WARNING

Make certain that sufficient clearance exists between fan and stationary parts and make certain fan and fan hub bolts are torqued. Failure to observe this precaution can result in serious injury and equipment damage.

WARNING

When circuit breakers are not included with the generator, the terminals on the ends of the stator lead wires are not insulated. These terminals must be insulated before generator set is operated. Failure to observe this precaution can result in serious injury and equipment damage.

CAUTION

Do not push on rotating rectifier or exciter winding. Failure to observe this precaution can result in equipment damage.

SECTION 1
GENERAL INFORMATION, PRINCIPLES OF OPERATION AND MECHANICAL CONSTRUCTION

GENERAL

KAMAG AC generators are brushless 4-pole machines producing 60 Hz power at 1800 rpm or 50 Hz power at 1500 rpm. The generators are of the revolving field type, having rotating field poles called the rotor and a stationary armature called the stator. All standard units are broad voltage range machines that have twelve lead wires brought out from the stator coil groups. This feature permits connection of the stator winding in either three-phase wye, three-phase delta, or single-phase configuration. Table 1 lists the voltages that can be obtained from the output of KAMAG generators.

Two bearing generators have a rotor shaft that extends beyond the driven end of the generator for mounting sheaves or a flexible drive coupling.

Drawings and tables are contained in Section 10 in this manual.

The major parts comprising the KAMAG generator are shown on Figure 1. Figure 7 is an electrical schematic of the generator field and exciter. The twelve stator lead wires and respective stator coil groups are shown on Figure 6 .

PRINCIPLES OF OPERATION

Ac generators require direct current flowing through the field winding to set up the magnetic flux which generates ac power in the stator winding. An exciter, which is a small ac generator with rectified output, provides this direct current. While the generator armature is stationary and the field rotates, the exciter field is stationary and the armature and rectifier rotate.

The exciter itself requires direct current for excitation. This excitation may be provided by any dc power supply that provides the proper excitation. However, in order to keep the generator output voltage relatively constant, the dc excitation must be automatically regulated by means of a voltage regulator.

The voltage regulator provides regulated dc excitation. This device measures the generator voltage and compares the measured voltage with a pre-set voltage established by adjustment of a voltage adjust potentiometer or rheostat. It then uses the result of the comparative process to automatically control the excitation supplied to the exciter field winding. This action in turn regulates the excitation applied to the generator field winding, which controls the magnetic flux and thereby the ac power generated by the generator stator winding.

The voltage regulator requires electrical power for operation of its circuitry. Usually a portion of the power generated by the generator is used to power the voltage regulator.

MECHANICAL CONSTRUCTION

The major parts comprising the KAMAG generator are shown in Figure 1 and described in the paragraphs that follow.

Generator Frame and Stator

Rectangular steel bars welded to endrings provide rigid support for the stator, the generator endbell, and the adapter. Weldments rigidly secure the stator to the frame bars.

The stator core is composed of a stack of thin, notched electrical steel laminations assembled under pressure and welded to the frame bars. The semi-closed notched slots are Class F insulated; random wound coils are firmly wedged in the insulated slots. The stator coils in KAMAG generators are connected in three-phase groups with twelve lead wires that terminate within the terminal box. Stator wire connections are insulated and the entire stator is then impregnated with thermo-setting 100 percent solid bonding epoxy and baked under a controlled cycle. This process minimizes voids and ensures high dielectric strength and excellent moisture resistance.

Generator Frame Cover

A removable sheet metal cover encloses the generator frame.

Generator Rotor Assembly

A precision machined steel shaft, the four-pole rotating field, the exciter armature and the rotating rectifier comprise the rotor assembly. Also mounted on the shaft and provided with a replacement rotor are the drive hub and the generator bearing. A two-section fan mounts on the rotor at the adapter end of the generator.

Katolight Service - Master Repair Manual - Page 698

The rotor is dynamically balanced at the factory. Rotor balance is attained by mounting weights on rings located at the front and back of the field poles.

A. Shaft

The rotor shaft includes a keyway and key at the drive end for mounting the drive sheaves or flexible coupling, a keyway and key for mounting the rotor field core, and a keyway and key for mounting the exciter armature and rotating rectifier.

B. Generator Field Poles

The four poles which carry the field windings are comprised of a stack of one-piece electrical steel laminations press-fitted together using a hydraulic press. Copper rods of the amortisseur winding are pressed into circular holes through the pole head portion of the core structure and welded to copper end plates that form the front and back section of the assembled field core structure. The field core structure is pressed on the shaft using a high pressure hydraulic press and keyed, forming a rigid rotating element. Round steel studs are pressed into each pole head for attachment of rotor balance rings at the front and back section of the field assembly.

Heavily insulated series-connected field coils are wound about the four poles. A support block made of insulating material provides coil support at the bottom and top of the field coil. Two lead wires are brought out to the rotating rectifier.

A thermo-setting epoxy is applied to the completed generator field assembly and the field assembly is baked under a controlled cycle to ensure high dielectric strength and mechanical strength.

C. Air Circulating Fan

The fan consists of two half-sections that clamp together and are held securely in place on the shaft by two steel bolts. The fan mounts at the drive end of the generator between the drive hub and the generator field poles.

Ambient air is drawn into the outboard end of the generator, and passes over the exciter, across the outside of the generator stator windings and stator laminations, and through the air gap between the generator stator and field poles. This circulation of air removes heat from the windings and laminations. The cooling fan exhausts the heated air from the generator.

D. Bearings

Two bearing KAMAG generators have duty-selected shielded ball bearings that are factory packed with lubricating grease. A machined housing at the center of the endbell located at the exciter end ofuhe machine supports the outer race of the outboard bearing. The machined bearing housing at the center of the adapter at the driven end of the generator supports the bearing located at the driven end of the generator. Bearing inner races are interference fit onto bearing journals machined on the generator shaft.

Exciter Rotor

The exciter rotor consists of the exciter armature wound with a three-phase winding and a full-wave rotating rectifier. Three-lead wires, one from each phase of the exciter armature winding, connect to the rectifier diodes as shown on Figure 7. The direct current from the rotating rectifier is conducted to the generator field through lead wires.

Two bolts mount the rectifier assembly to the exciter armature core structure. The entire exciter rotor unit slides over the generator shaft and is held in place by a rectangular key located in the shaft keyway and a retaining bolt and washer at the outboard end of the shaft as shown on Figure 2.

A. Exciter Armature

The exciter armature core structure is comprised of a stack of thin, notched, one-piece laminations held assembled under pressure and kept compressed and aligned by steel rivets through the stack of laminations. The semi-closed slots are insulated with Class F insulation, and the coils of the three-phase exciter armature winding are then securely wedged in the slots. The entire exciter armature is completely impregnated with thermo-setting epoxy and baked under a controlled cycle. Three lead wires, one from each phase of the exciter armature winding, connect to the rotating rectifier as shown on Figure 7.

B. Rectifier

The exciter armature three-phase ac output is applied to a full-wave rectifier comprised of a positive heat sink, a negative heat sink, a molded insulating plate, a metal plate, three forward polarity diodes, three reverse polarity diodes, a forward polarity zener diode, and a reverse polarity zener diode. The heat sinks are molded onto the insulating plate. The three forward polarity diodes and the forward polarity zener diodes mount on the positive heat sink, while the three reverse polarity diodes and the reverse polarity

zener diode mount on the negative heat sink. A generator field lead wire attaches to the positive heat sink while the second generator field lead attaches to the negative heat sink. This rectifier output circuit provides excitation to the series-connected generator field winding. Three wires, one from each phase of the exciter armature winding, attach to the diodes as shown in Figure 7. The complete rectifier assembly is held in place on the exciter armature by two bolts.

Exciter Field Assembly

The exciter field core structure is comprised of a stack of thin, notched electrical steel laminations that are held axially and tangentially aligned by a weldment across the stack of laminations. The steel laminations are of the type that retain residual magnetism. This residual magnetism produces a magnetic field which, when the generator is started, induces current in the exciter armature, providing the generator field with sufficient dc excitation for generator voltage build-up.

The slots in the exciter field core structure are insulated with Class F insulation and the coils are then firmly wedged in the slots. The coils are series connected; lead wires are brought out for connection to the voltage regulator dc output. The entire exciter field assembly is completely impregnated with thermo-setting epoxy and baked under a controlled cycle. Bolts that pass through holes in the exciter field core structure and thread into tapped holes in the bosses located on the generator endbell provide rigid mounting and ensure concentric alignment.

Endbells

Cast iron endbells enclose the outboard and driven ends of the generator. Precision machined matching pilot and recess on the endbell and generator frame endring ensure concentric alignment with the generator frame. The endbells are rigidly secured to the frame by bolts that pass through holes in the endbell and thread into tapped holes in the frame endring. A machined bearing housing at the center of the endbell supports the outer race of the generator bearing. The outboard endbell includes bosses with tapped holes which provide mounting for the exciter field assembly.

Terminal Box

KAMAG generators include a large terminal box with ample room inside for the voltage regulator, most circuit breakers, and other options. The twelve generator stator lead wires and the exciter field leads terminate within the terminal box. The terminal box mounts on the outboard end of the generator.

SECTION 2
RECEIVING, INSPECTION, HANDLING INSTRUCTIONS AND STORAGE

RECEIVING YOUR KAMAG GENERATOR

Upon receipt of the generator it is recommended that it be carefully examined to determine if any shipping damage has occurred before accepting the shipment from the transportation company.

Generators received during freezing weather should be slowly warmed to prevent condensation of moisture on the windings.

WINDING INSPECTION

Winding inspection prior to operating the generator is recommended. If moisture is observed or condensation of moisture on the windings is suspected, a test of the stator winding insulation resistance should be made. If the result is less than the minimum value, the generator should be dried out.

Insulation resistance of the stator winding in the KAMAG generator should not be less than 1.48 megohms when calculated by the formula that follows.

$$\text{Minimum Winding Insulation Resistance in Megohms} = \frac{\text{Rated Voltage of Generator}}{1000} + 1$$

UNPACKING

Unpack the generator carefully. Make certain that foreign material such as crating nails and packing material does not enter the generator. Read all instruction cards and keep all instructions, drawings, and test cards with the generator as this information will be required by personnel when installing, operating, and servicing the equipment.

When lifting your KAMAG generator, attach an overhead crane to the lifting eye(s) located on the generator frame. Apply lifting force in a vertical direction if possible. Make certain that crane, lifting cables, and other hardware used is of sufficient strength to safely lift the weight of the generator. Generator weight may be determined by referring to the weight given on the shipment bill of lading.

WARNING

Do not lift complete generator set by means of lifting eye(s) on generator. Disregarding these instructions may result in serious injury or equipment damage.

WARNING

Do not apply any lifting force to generator fan for lifting or turning generator rotor. Failure to observe this instruction may result in serious injury or equipment damage.

STORAGE

When the generator will not be installed immediately it is recommended that it be stored in a clean, dry area which is not subject to rapid changes in temperature and humidity.

When storage will be for a period of six months or longer it is recommended the unit be wrapped with a thin water proof protective covering, and that a moisture absorbing agent such as bags of silica jel be placed within the covering.

SECTION 3
MOUNTING AND ALIGNING GENERATOR SET

HANDLING

A lifting eye is provided on top of the generator frame. The generator may be moved into position on the generator set base by means of an overhead hoist. Apply lifting force in vertical direction. Avoid applying angular force on the lifting eye.

WARNING

Lift vertically only. Angular force increases tension in hoist cable and applies shear force on lifting eye. Excessive angular force can result in breakage of cable or lifting eye which could cause serious injury and equipment damage.

After the generator and prime mover have been mounted on a single base, any further transporting or handling of the entire assembly must be made by using the lifting fixture provided on the base.

WARNING

Do not use generator lifting eye to lift entire generator set comprised of generator base and prime mover. Failure to observe this warning can result in serious injury and equipment damage.

BASES AND BED PLATES

A. Belted Generator Sets

Belt driven generator and its prime mover may be solidly mounted on a single base, separate bases, bed plates, or mounted directly on a level foundation.

In applications where vibration isolators are required, both the generator and its prime mover must be mounted on a single base of rigid construction with vibration isolators installed between the base and foundation.

B. Flexible Coupled Generator Sets

Where application requires that the generator and prime mover shafts be coupled with flexible couplings, both the generator and its prime mover must be mounted on a single base. Vibration isolators may be installed between the base and foundation.

Bases selected for flexible coupled operation must not twist or bend during mounting or operation of the generator set because maintaining alignment of the flexible coupling is important for maximum coupling life, maximum bearing life and minimizing vibration.

EXCITER ALIGNMENT AND BEARING ENDCLEARANCE

The generator is provided with factory lubricated shielded anti-friction ball bearings. Excessive thrust load will shorten bearing life and increase noise and vibration. In order to avoid thrust loading of the bearing, clearance should exist between the bearing and machined end of the bearing housing. Before coupling the generator to the prime mover, check to made certain bearing endclearance is correct. In applications where generator is driven through flexible coupling, care should be taken to make sure generator shaft is not pulled out of alignment while coupling and aligning the generator set.

Excessive axial misalignment of the exciter can result in lower than normal generator field excitation. This can result in excessive exciter field current under all loads from no-load to full load and lower than normal generator voltage when operating with load applied. Exciter alignment should be checked before coupling the generator to the prime mover and again after the generator has been coupled and aligned.

The rotor in KAMAG two bearing generators should have unrestrained axial travel from 1/16 inch to 3/32

inch. Each bearing in the two bearing KAMAG generator should have 1/32 inch to 3/64 inch endclearance. Check may be made by measuring length of shaft at driven end of generator as follows:

1. Pull rotor forward (towards drive end) until it stops. Front bearing will now have zero endclearance.
2. Measure length of shaft that extends beyond drive endbell.
3. Push rotor back until it stops. Rear bearing will now have zero endclearance.
4. Again measure length of shaft that extends beyond drive endbell.
5. Compute total rotor travel. Shaft length measured during step 2 minus shaft length measured during step 4 equals total rotor travel.
6. Compute one-half total rotor travel.
7. Pull rotor forward the distance determined during step 6. Rotor should be centered and each bearing should have correct endclearance.
8. Measure and record length of shaft that protrudes beyond drive endbell. This measurement should be used to determine that rotor has remained aligned during coupling and alignment of the generator set and also after generator set has been operated.
9. Check to make certain exciter is satisfactorily aligned. Axial misalignment between the exciter field core and exciter armature core should not exceed 0.125 inch.
10. After generator set is mounted, coupled, and aligned, check exciter alignment and verify that the length of shaft that extends beyond drive endbell is the same as that measured during step 8.

SELECTION OF DRIVES FOR TWO-BEARING GENERATOR

Satisfactory generator operation will depend upon intelligent selection of drive couplings. In general, solid couplings are not recommended except when the generator and prime mover frames are directly connected. Belt drives should not be used when belt speed exceeds 5000 feet per minute.

BELT DRIVES

Proper alignment and tightness of belt drives is essential. Improper alignment and belt tightness will increase belt wear as well as bearing load and vibration. Select belt drive in accordance with belt manufacturer's specifications. Make certain generator and prime mover are rigidly mounted. In general, belt drives are not recommended when belt speed exceeds 5000 feet per minute.

A. V-BELT

Use only matched belt sets and avoid minimum pitch sheaves and belts. Follow the manufacturer's specifications of NEMA limits for sheave pitch.

Make certain the shaft axis of the prime mover and generator are parallel. Belts must enter and leave sheaves with no side bending. Tighten just enough to prevent slippage at full load. Never grease or use belt dressing on belts.

B. SYNCHRONOUS BELTS

Synchronous belts have evenly spaced teeth on the bottom surface that mesh with grooves on the pulleys. In general, installation of synchronous belts will be the same as for flat belts. The following precautions should be taken when installing a synchronous belt drive.

1. Belts should be installed with snug fit, neither too tight nor too loose. High initial tension is not necessary but when torque is unusually high, a loose belt may "jump grooves". If the belt jumps the grooves the tension should be increased gradually until satisfactory operation is attained.
2. Be sure that shafts are parallel and pulleys are in alignment. On a long center drive, because of the tendency of the belt to run against the flange, it is sometimes advisable to offset the driven pulley to compensate.
3. On a long center drive, it is imperative that belt sag is not enough to permit teeth on the slack side to engage the teeth at the tight side.
4. It is important that both prime mover and generator are mounted rigidly to prevent variation in belt tension.
5. Although belt tension requires little attention after initial installation, provision should be made for some center distance adjustment for ease in installing and removing belt. Do not force belt over flange of pulley.

FLEXIBLE COUPLINGS

In applications where these types are used instead of belt drives, the generator and prime mover must be solidly mounted on a rigid base and shafts must be carefully aligned. Prior to installing the coupling half-sections the generator and prime mover shafts should be adjusted to a position that provides bearing end clearance; they should be carefully maintained at that position while mounting and coupling the units. When mounting the units and installing coupling half-sections, be sure to maintain clearance between shaft ends and check the generator exciter axial alignment. Where base mounts solidly to foundation, care should be taken to ensure foundation is level because mounting base to an uneven foundation could twist or bend base and cause coupling misalignment.

In application where vibration isolators are installed between the base and foundation, care should be taken to make certain base will support the weight and torsional load without bending or twisting.

ALIGNING FLEXIBLE COUPLINGS

Where flexible coupling drives are used, the generator and prime mover shaft centers must be in line. This is done by checking parallel or shaft offset alignment and angular alignment. Recommended method is given in the procedures that follow.

To correct alignment, shims may be installed between the generator mounting feet and the base and the prime mover mounting feet and the base. Alignment should be checked while mounting and coupling the generator set, then checked again after the generator set has been completely coupled and mounted on the base and the base has been installed on the foundation. Parallel and angular alignment tests may be done consecutively using one dial indicator, or simultaneously when two dial indicators are used.

A. Checking Parallel (Shaft Offset) Alignment

1. Mount dial indicator as shown in Figure 4. Where sufficient space exists, dial indicator may be mounted as shown in Figure 4(a). In applications where coupling halves are close together or when coupling is slightly out-of-round and not concentric with respect to the shaft centerline, fabricate rigid brackets and install brackets and dial indicator as shown in Figure 4(b).
2. Turn shafts simultaneously through one complete revolution observing dial indicator as shafts are turned.
3. Shafts should not be offset more than .002 inch total indicator reading (T.I.R.).
4. If offset is more than .002 inch T.I.R., install shims under generator or prime mover mounting feet, secure mounting bolts and again test alignment.
5. Repeat steps 2 through 4 until shaft offset is .002 inch or less.
6. Retest parallel (shaft offset) and angular alignment after coupling has been completely assembled, generator set mounting bolts have been tightened, and base has been secured to foundation. Mount dial indicator (or when used, "L" brackets) on outer surface of coupling hubs or on the shafts.
7. If T.I.R. exceeds .002 inch, check to make certain generator set base is level and has not twisted or bent. One or more of the following steps may be necessary:
   a. Level foundation.
   b. Place shim between base and foundation.
   c. Strengthen base.

B. Checking Angular Alignment

1. Mount dial indicator as shown in Figure 5. Where sufficient space exists, dial indicator may be mounted as shown in Figure 5(a). In applications where coupling halves are close together or coupling face run-out exists,fabricate rigid brackets and install brackets and dial indicator as shown in Figure 5(b).
2. Turn shafts simultaneously through one complete revolution, observing dial indicator as shafts are turned.
3. Total indicator reading (T.I.R.) should not exceed .001 inch per inch of radius from shaft center.
4. Correct excessive angular misalignment either by turning the generator or prime mover on the base until shafts are aligned, or by installing shims between mounting pads and the base.
5. Repeat steps 2 through 4 until satisfactory angular alignment is attained.

6. Retest angular and parallel alignment after coupling has been completely assembled, generator set mounting bolts have been tightened, and base has been secured to foundation. Measure by installing dial indicator across outside of coupling or, where "L" brackets are used, mount brackets on shafts as close to the coupling as possible.
7. If excessive shaft offset or angular misalignment exists, check to make certain base has not bent or twisted. One of the following may be necessary.
    a. Level foundation.
    b. Place shim between base and foundation.
    c. Strengthen base.

SECTION 4
ELECTRICAL CONNECTIONS

GENERAL

KAMAG generators have twelve stator lead wires that terminate within the terminal box. The two lead wires from the exciter field winding also terminate within the terminal box.

The generator may be connected three-phase series wye, three-phase parallel wye, three-phase series delta, three-phase parallel delta or single phase. The units may be operated 60 Hertz, 1800 rpm or 50 Hertz, 1500 rpm. The voltage regulating system voltage control rheostat permits adjustment of generator output voltage.

Voltage generated when stator lead wires are connected in one of the configurations described above is listed in Table 1. Select the hookup that will provide the appropriate voltage. Be sure to connect the generator stator, load lines and voltage regulator as shown in the wiring diagram provided with the generator. Observe the general precautions that follow.

A. Three-Phase Wye Connected Generator

For a 4-wire system the neutral line may be brought out to the load distribution system. Where electrical code requires system ground, be sure the neutral leg is electrically connected to ground stud or ground wire.

B. Three-Phase Delta Connected Generator

Where generator is connected 3-wire delta, the stator connection neutral should not be connected to the ground stud and load lines do not contain a neutral line. The load conductors (phase A, B, and C) should not be grounded.

C. Single Phase Three Wire

Neutral (N) and two load conductors (L1 and L2) are contained in the load distribution system. Where electrical code requires system ground, neutral leg may be grounded.

D. Single Phase Two Wire

Two load conductors connect to the load distribution system. In single phase two wire 200-240 VAC applications where generator neutral is grounded, the two load conductors must not be grounded.

E. Generator Frame Ground

Generator frame should be connected to an earth ground in accordance with electrical code. Ground wire must be connected to the generator ground stud located above the left mounting foot.

F. Exciter Field Lead Wires

Exciter field lead wires F+ and F- connect to the voltage regulator output terminals F+ and F-. Be sure to maintain polarity. THIS CIRCUIT MUST NOT BE EITHER GROUNDED OR OPENED WHILE GENERATOR IS RUNNING.

G. Voltage Regulator

Refer to the voltage regulator instruction manual and the wiring diagram provided with the generator set. Make certain all internal and external connections are correct before operating the generator set.

CAUTION

Incorrect electrical connection of the voltage regulator can result in immediate equipment damage.

H. Voltage Regulator Fuse

This fuse protects the voltage regulator circuitry.

In applications where the generator set does not include a field circuit breaker it is recommended that a 1 1/2 ampere normal blow fuse be used in the voltage regulator. This is to protect the KAMAG generator against excessive voltage due to loss of sensing and excessive field forcing.

I. Voltage Shutdown Switch (Engine Idle Switch)

Where this accessory is provided, connect as described in the voltage regulator instruction manual and generator set wiring diagram.

J. Field Circuit Breaker

Where this accessory is provided, connect as described in the voltage regulator instruction manual and the generator set wiring diagram.

K. Automatic/Manual Voltage Control

Where this accessory is provided, connect as described in the voltage regulator instruction manual and the generator set wiring diagram.

L. Space Heaters

Where this accessory is provided, connect as described on the generator set wiring diagram.

SECTION 5
OPERATION

PRE-START INSPECTION

Before operating the generator for the first time, the following checks are recommended.

WARNING

When circuit breakers are not included with the generator, the terminals on the ends of the stator lead wires are not insulated. These terminals must be insulated before generator set is operated. Failure to observe this precaution can result in serious injury and equipment damage.

1. Make certain generator set base is level. Check to make sure bolts that mount the generator and prime mover onto the base are tight. Refer to procedure given in Section 3.
2. On belted generator set, make certain drive sheaves are aligned and belts do not have excessive slack. Where variable sheaves are used, check to make certain sheaves are adjusted to provide correct rpm. Check rpm with tachometer during initial startup of the unit.
3. On flexible coupled generator set, make sure coupling is aligned and generator bearings have end clearance. Refer to procedure given in Section 3.
4. Check to make sure fan bolts are tight and space exists between the fan and stator windings. Check to make sure exciter retaining bolt is tight.
5. Check all wiring against the proper connection diagrams and make sure all connections are properly insulated.
6. Inspect to make sure all packing materials and shipping support blocking has been removed. Remove loose cloths and tools.
7. Install covers and guards.

FIELD FLASHING

The generator relies on residual voltage to start the generator action which in turn generates the rated voltage. If the generator fails to generate voltage after it has come up to rated speed, it may be necessary to flash the exciter field. Field flashing must be done while the generator is at a standstill as described in the procedure that follows.

1. Stop the engine and open the output circuit breaker.

CAUTION

Be sure to maintain polarity (+) to (F+) and (-) to (F-).

2. Connect the negative lead (-) from a common 12 volt storage battery onto exciter field lead F-.
3. Connect the positive lead (+) from the battery onto exciter field lead F+. Only a few seconds flashing should be necessary.
4. Remove battery and connect exciter field leads onto voltage regulator terminals F+ and F-. Be sure to maintain correct polarity.
5. Start generator and check for satisfactory voltage build up.

VOLTAGE ADJUSTMENTS

A means for adjusting the voltage is incorporated in the regulator. For details refer to the voltage regulator instruction manual applicable for this unit.

VOLTAGE RANGE ADJUST

This control is incorporated in most voltage regulators. For details refer to the voltage regulator instruction manual applicable for this unit.

STARTING UP THE GENERATOR FOR SINGLE UNIT OPERATION

The following procedures should be followed for starting up the generator set.

1. The generator output must be disconnected from the load. Be sure the main circuit breaker is open.
2. If fuses have been removed, install the fuses.
3. Where generator set is equipped with field circuit breaker, set breaker to ON.
4. Where generator set is equipped with voltage shutdown switch, set switch to RUN position.
5. Where generator set is equipped with Automatic/Manual control, set switch to AUTO position.
6. Where space heaters have been supplied with the generator set, turn off the heater before operating the generator.
7. Where generator sets are equipped for parallel operation and include UNIT/PARALLEL switches, set switch to UNIT position whenever generator is operated singly.
8. Start generator set and bring to rated speed. Adjust voltage to required value by means of the voltage adjust rheostat.
9. Close the main circuit breaker and apply load.
10. Before stopping the generator set, remove the load by tripping the main circuit breaker.

SECTION 6
PREVENTIVE MAINTENANCE

INSPECTION

To ensure peak performance and maximum service life, the generator must be kept in good condition. This can best be ensured by periodic inspection of the unit and immediate repair of minor problems. The preventive maintenance inspection schedule that follows is enclosed as a guide for establishing a preventive maintenance program.

A. Daily or Whenever Generator is Operated

1. Before starting generator be sure air inlet and air exhaust screens are not clogged.
2. On belt driven generator application, check drive belts for wear and correct tension.
3. While generator is running be sure voltage is correct and not oscillating.
4. While generator is running observe any unusual noise or vibration.

B. Once Every Six Months

1. Remove terminal box cover and inspect wiring for signs of damaged insulation and loose or corroded connections. Repair damaged wiring; clean and tighten connections.
2. Inspect control devices for accumulation of dust, moisture or other foreign material. Clean using nylon bristle brush or compressed air at pressure between 25 PSI and 50 PSI.
3. Inspect to make certain that bolts which mount the voltage regulator, circuit breakers, meters, etc. have not loosened. Tighten as necessary.
4. Remove or loosen cover that surrounds generator frame. Inspect inside of generator frame. Inspect inside of generator for signs of damaged winding insulation and excessive dirt or moisture. Inspect to make certain bolts are tight.
5. Check to make sure generator set base is level. Check to make certain generator and its prime mover are solidly mounted on base.
6. On belted generator set applications, check belts for general condition and proper tightness (see Section 3).
7. On flexible coupled generator set applications, check coupling alignment (see Section 3). Where coupling is grease lubricated, lubricate coupling in accordance with the coupling manufacturer's instructions.

CLEANING

A. Controls

Clean using nylon bristle brush or compressed air at pressure between 25 PSI and 50 PSI.

B. Generator

Wipe exterior of generator and air intake and exhaust with cloth or nylon bristle brush. Clean loose dust or other abrasive material from generator interior using compressed air at pressure between 25 PSI and 50 PSI.

SECTION 7
TROUBLESHOOTING

GENERAL

Loose, corroded, or broken connections and wiring errors are often the cause of generator malfunction. Before assuming problem is within the generator or voltage regulator, check condition of wiring and terminal connections and verify wiring according to wiring diagrams provided with the generator set.

TROUBLESHOOTING PROCEDURE

The troubleshooting information that follows is divided by symptoms. They are: no voltage, low voltage, high voltage, and voltage fluctuating.

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

A. No Voltage

1. Shut down the generator set.
2. Remove terminal box cover and check generator leads and interwiring to the voltage regulator for loose or broken connections.
3. Check regulator fuses with ohmmeter. If defective, replace.
4. Start up generator. Measure ac voltage at input power terminals on the voltage regulator. The voltmeter reading should exceed 7 vac. If it does not, field flashing is required. Refer to field flashing procedure in Section 5 of this manual.
5. Where voltage reading before or after field flashing exceeds 7 vac but output voltage fails to build-up, shut down the generator set. Then proceed as described to either step 6 or steps 7 and 8 that follow.
6. Connect meters as shown in Figure 8. Then start generator set and measure exciter field excitation as described in Section 8.
7. Shut down the generator set. Disconnect voltage regulator by removing the voltage regulator fuse. Where regulator does not include fuse, disconnect voltage regulator by removing the connections to the regulator input power terminals. Insulate terminal lugs on wires to prevent grounding during test described in step 8 that follows.
8. Disconnect wires F+ and F- from regulator output terminals F+ and F-. Connect a common 12 volt storage battery to wires F+ and F-, keeping the polarity the same. Start up the generator set. While the generator is operating at a rated speed, read the voltage output of the generator measured by a voltmeter. If the reading is one-half or greater of the rated output when there is no load on the generator, the problem is in the voltage regulator. If the voltage remains near zero, the voltage regulator is good, and the problem is most likely within the exciter or generator. Shut down the generator. Reconnect the voltage regulator and proceed to step 9.
9. Remove cover located on end of terminal box. Examine the rectifier diodes for loose or broken connections. Proceed to step 10.
10. Test the generator exciter rotating rectifier diodes as described in the procedure contained in Section 8. Refer to Figures 3 and 7. Install diodes as described in Section 9 and then reconnect generator field leads.
11. Test zener diode surge suppressor as described in Section 8. Reverse polarity zener diode is located on the exciter rectifier negative heat sink, while the rectifier positive heat sink mounts a forward polarity zener diode. Part location and electrical connections are shown on Figures 3 and 7. Install and torque zener diode 15 inch-lbs. Connect zener diodes together and connect generator field leads (see Figure 3). If above test indicates zener diodes were good, proceed to step 12.
12. Check windings for continuity as described in the winding resistance test procedure contained in Section 8. If opens or shorts are found in the exciter stator or exciter armature, replace the necessary component. If the condition is found in the generator stator or the generator rotor field winding, major repair or generator replacement is probably required.
13. Connect wiring in accordance with wiring diagram(s) provided with the generator set.

Katolight Service - Master Repair Manual - Page 711

B. Low Voltage

1. Test using auxiliary voltmeter connected at generator load leads.
2. Shut down the generator set.
3. Remove cover located at end of terminal box. Check main generator leads and wiring to the voltage regulator for correct connection. Make certain that connections are tight and not corroded.
4. Start up the generator set. Verify correct speed (1800 rpm for 60 hertz and 1500 rpm for 50 hertz).
5. Be sure the voltage adjust rheostat is adjusted as necessary to increase generator voltage.
6. Adjust the voltage range potentiometer clockwise to increase generator voltage.
7. Where voltage is normal with no-load applied but drops with load applied, make certain load does not exceed nameplate capacity. Verify using clamp-on ammeter on the generator load lines. Current in any line must not exceed nameplate amps.
8. Shut down the generator set and open the output circuit breaker.
9. Check wiring to the voltage regulator sensing and input power terminals. Where voltage regulator has multi-tap sensing transformer, make certain connections to the transformer are correct. Where voltage regulator has different internal connections for 60 hertz and 50 hertz operation, verify connections are correct. Where voltage regulator is of the series boost saturable transformer type, verify that boost winding is connected correctly. Refer to the voltage regulator instructions and the wiring diagrams provided with the generator set. Where connections are found to be correct, proceed as follows.
10. Continue by testing either field excitation as described in step 11 or test using battery as described in steps 12 through 14.
11. Connect meters as shown in Figure 8. Then start generator set and measure exciter field excitation as described in Section 8.
12. Disconnect the voltage regulator by removing wires at the regulator input power terminals and the regulator output terminals F+ and F-. Tape ends of input power wires to prevent accidental ground or short during the test described in step 11.
13. Connect a common 12 volt storage battery to exciter field lead wires F+ and F-, keeping the polarity the same. Start up the generator set. While the generator is running at rated speed, read the voltage output. If the reading is one-half or greater when there is no-load on the generator, the problem is in the voltage regulator. If the reading remains near zero, the problem is most likely within the exciter or generator.
14. Shut down the generator set. Remove battery and reconnect voltage regulator determined to be in good condition. If preceding test indicated that the problem was within the exciter or generator, test as described in the steps that follow.
15. Remove the cover located on end of terminal box. Examine the rotating rectifier diodes for loose or broken connections. If connections are good, proceed to step 16.
16. Test rotating rectifier diodes using an ohmmeter as described in Section 8. If one reading is high and the other is low, the diode is good. A shorted diode will have very low resistance in both forward and reverse polarity while an open circuited diode will exhibit high resistance in both forward and reverse polarity. Install good or replacement diodes as described in Section 9. Connect generator field leads.
17. Test zener diode surge suppressors as described in the procedure contained in Section 8. Install, torque, and wire zener diode surge suppressors as described in Section 9. Reconnect generator field leads. If test indicated zener diodes were good, proceed to step 18.
18. Check windings for continuity as described in the winding resistance test procedures contained in this manual. If opens or shorts are found in the exciter stator or exciter armature, replace the necessary component. If the condition is found in the generator stator or rotor, major repair or generator replacement is probably required.

C. High Voltage

1. Verify by testing with an auxiliary voltmeter at the generator load lines.
2. Be sure the voltage adjust rheostat is adjusted as necessary to reduce voltage.
3. Adjust the voltage range potentiometer in the voltage regulator counter-clockwise to reduce voltage.
4. Shut down the generator set and open the generator output circuit breaker.
5. Remove terminal box cover and check generator set wiring for correct connection.

6. Check wiring to the voltage regulator sensing and input power terminals for correct connection. Check voltage regulator sensing transformer for correct connection. Where voltage regulator includes different internal connections for 50 Hertz or 60 Hertz, verify that connections are correct. Where voltage regulator is of the type that has boost transformer or winding, verify that connections are correct. Refer to the wiring diagrams provided with the generator set and the voltage regulator instructions.

D. Voltage Fluctuating

1. Verify generator voltmeter performance using auxiliary voltmeter at generator lines.
2. Verify with a tachometer to ensure stable speed.
3. Where generator is providing power to SCR type load, transient voltage spikes during SCR switching can cause voltage to fluctuate. If this is the case, set stability adjust for slower regulator response.
4. Adjust voltage regulator stability control potentiometer as described in the voltage regulator instruction manual. Test with no load applied and again with load applied.
5. Shut down generator set and open generator output circuit breaker. Remove the terminal box cover and check all wiring for loose connections.
6. Where wiring is found to be correct and in good condition, proceed to either step 7 or steps 8 and 9.
7. Connect meters as shown on Figure 8 and measure exciter field excitation as described in Section 8.
8. Shut down generator set and remove cover located on end of terminal box. Proceed to step 9.
9. Disconnect the voltage regulator by removing the connections to the regulator input power terminals. Tape lugged ends on wires to prevent ground or short during test. Remove F+ and F- exciter field lead wires from the F+ and F- terminals on the voltage regulators. Connect a common 12 volt storage battery onto exciter field leads F+ and F- keeping the polarity the same. Start up the generator set. While generator is operating at rated speed, read the voltage output on a voltmeter. Following this procedure, if the voltage is one-half or greater of rated output and does not fluctuate when there is no load on the generator, the problem is within the voltage regulator. Consult the voltage regulator instruction manual for further information.

SECTION 8
GENERATOR TESTS

MEASURING EXCITER FIELD EXCITATION

Exciter field excitation can be measured using a dc voltmeter and dc ammeter connected in the circuit between the voltage regulator dc output and exciter field as shown in Figure 8. The meters must be capable of measuring full load excitation. This will vary according to the size of the generator and can be determined from the test card attached to the generator or by contacting Kato Engineering/Reliance Electric, Mankato, Minnesota. Be sure to provide the generator serial number when requesting information.

Procedure

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

1. Connect dc voltmeter and dc ammeter as shown in Figure 8.
2. Start unit and run at rated speed.
3. Measure no-load excitation. The following abnormal conditions could occur.

   a. Generator Output Voltage Low, with Normal or Higher than Normal Excitation

   If this condition occurs, the problem is within the generator or exciter. Test the rotating rectifier diodes and winding resistance.

   b. Generator Voltage Low and Excitation Low

   If this condition occurs, the problem is within the voltage regulator or the wiring to the voltage regulator.

   c. No Generator Voltage and No Excitation

   If this condition occurs, flash exciter field to restore residual magnetism as described in the procedure given in Section 5 in this manual.
4. Measure excitation with full load applied. The following abnormal conditions could occur.

   a. Generator Voltage Low and Full-Load Excitation Normal or Higher Than Normal

   If this condition occurs, verify that speed is not low. Make certain load does not exceed rated full load current given on the generator nameplate.

   b. Generator Voltage Low and Full Load Excitation Low.

   If this condition occurs, problem is within the voltage regulator.

TESTING EXCITER ROTATING RECTIFIER DIODES

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

Stop generator set. Remove cover located on end of terminal box. Test as described in the procedure that follows using ohmmeter or three-volt test light.

NOTE: Where three-volt test light is used: bulb should light when connected in low resistance circuit and should not light when connected in high resistance circuit.

1. Unsolder wire connected to diode, then remove diode from heat sink (see Figure 3).
2. Measure resistance across diode. Reverse meter probes and again measure resistance.

   A good diode will have low resistance in the normal direction of current flow and high resistance to reverse current. High resistance both forward and reverse indicates diode has become open and should be replaced. Where light is used, failure of bulb to illuminate in both forward and reverse tests indicates an open diode.

   Very low resistance both forward and reverse indicates a shorted diode.

   Where light is used, diode is shorted when light illuminates during both forward and reverse polarity test.
3. Install diode. Torque 15 inch-pounds. Where original diode is replaced, make sure replacement diode is of the same rating and polarity.

4. Solder wire onto diode (see Figures 3 and 7).
5. Repeat steps 1 through 4 until each diode has been tested.

TESTING ZENER DIODE SURGE SUPPRESSOR

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

Stop generator set. Remove cover located on end of terminal box. Using an ohmmeter, measure zener diode forward polarity and reverse polarity resistance as described in the procedure that follows.

1. Unsolder wire that connects the zener diode located on the negative heat sink to the zener diode located on the positive heat sink. Then remove zener diode (see Figures 2 and 3).
2. Measure resistance across zener diode. Reverse meter probes; again measure resistance. Zener diode in good condition should have very high resistance, near infinity (∞) in one direction and resistance in the range of 1.25 to 3.0 megohms in the opposite direction.

   Very low resistance in both forward and reverse polarity indicates zener diode is short circuited and should be replaced while infinity resistance both forward and reverse indicates zener diode is open circuited and should be replaced.
3. Install zener diode. Torque 15 inch-pounds. Where original zener diode is replaced, make sure replacement zener diode is of the same rating and polarity (see Figures 3 and 7).
4. Test second zener diode as given in steps 1 through 3.
5. Carefully solder wire connecting zener diodes together (see Figures 3 and 7).

MEASURING WINDING RESISTANCE

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

Resistance test of winding may be made to determine whether winding has become open circuited. Resistance measured across a winding that has become open circuited will be very high (near infinity). In the case of shorted turns, resistance will generally be lower than normal. Where shorted turns are suspected, additional test using growler is recommended. Short to ground may be determined by testing winding insulation resistance using a hand cranked 500 VDC megger.

Resistance of winding will vary in proportion to the winding temperature. Where winding temperature is either higher or lower than 25°C (77°F), the formula that follows should be used to compute resistance.

$$\text{Resistance at } 25^\circ\text{ C} = \text{Measured Resistance} \times \frac{234.5 + 25}{234.5 + \text{Winding temp. in } ^\circ\text{C}}$$

A. Measuring Exciter Field Winding Resistance

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Remove exciter field leads F+ and F- from the F+ and F- terminals on the voltage regulator.
3. Connect ohmmeter onto exciter field leads F+ and F- and measure exciter field winding resistance.
4. Where winding temperature is either high or lower than 25° C, compute resistance as given in the formula contained in preceding topic "Measuring Winding Resistance."
5. Before starting generator set be sure to connect field leads onto voltage regulator terminals F+ and F-. Maintain correct polarity (F+ to F+ and F- to F-).

B. Measuring Generator Field Winding Resistance

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Remove generator field leads from the exciter rotating rectifier heat sink (+) and (-) terminals.
3. Connect test instrument such as Wheatstone bridge or Kelvin bridge onto generator field leads and measure generator field winding resistance.
4. Where winding temperature is either higher or lower than 25°, compute resistance as given in the formula contained preceding topic "Measuring Winding Resistance."
5. Before starting generator set, be sure to connect generator field leads onto the rotating rectifier heat sinks. Maintain correct polarity (positive to + and negative to -).

C. Measuring Exciter Armature Winding Resistance

This test requires removing the exciter armature lead wires from the exciter rotating rectifier diodes (refer to Figures 2 and 3).

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Observe which of the exciter rotating rectifier diodes each of the three exciter armature leads connect to. Then unsolder any two of the three exciter armature lead wires.
3. Measure exciter armature phase-to-phase resistance using test instrument such as Kelvin bridge connected between exciter armature phase 1 lead wire and phase 2 lead wire. Repeat measuring from phase 1 to 3 and again phase 2 to 3.
4. Phase to phase resistances should be quite similiar. Where winding temperature was either higher or lower than 25° C, compute resistance as given in formula contained in preceding topic entitled "Measuring Winding Resistance."
5. Before starting generator set be sure to solder leads onto the exciter rotating rectifier diodes (refer to Figures 3 and 7).

D. Generator Stator Winding Resistance

The stator has twelve lead wires brought out from the coil groups permitting connection of the generator stator winding series wye, parallel wye, series delta, parallel delta, or single phase. It is recommended that when testing winding resistance the stator be connected three-phase series wye by connecting the stator leads as shown in Figure 6.

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect the twelve generator stator leads numbered 1 through 12 from outgoing load lines, and the leads to voltage regulator, current transformers, and meters.
3. Connect stator leads in series wye configuration as shown in Figure 6 (a).
4. Measure resistance Phase 1 to 2 using a Kelvin bridge. Then measure Phase 1 to 3 and Phase 2 to 3. Phase to phase resistances should be quite similiar. Where winding temperature was either higher or lower than 25° C, compute resistance as given in formula contained in preceding topic entitled "Measuring Winding Resistance".
5. Connect generator wiring as shown on the wiring diagram provided with the generator set.

MEASURING WINDING INSULATION RESISTANCE

Observe the safety precautions in the Safety Summary at the front of this manual before operating, testing or making repairs to this equipment.

The insulation resistance will slowly decrease over the normal life of the generator. Test will indicate abnormal decrease in insulation resistance. Where insulation resistance test is to be made, use a 500 VDC hand cranked megger.

A. Measuring Generator Stator Winding Insulation Resistance

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect wiring from the twelve generator stator lead wires.
3. Connect stator leads in series wye configuration as shown on Figure 6 (a). Be sure to remove neutral lead from ground connection.
4. Connect megger ground lead to generator frame.
5. Connect megger lead onto phase 1 stator lead wire number 1. Make certain no connections other than the megger ground lead are touching the generator frame or other metal parts.
6. Test stator winding insulation resistance. Resistance should not be less than 1.48 megohm. If insulation resistance is lower than minimum value given above, determine cause of low insulation resistance. If due to wet windings, dry out the generator as described in Section 9 in this manual.

7. Before operating generator, connect wiring as shown on the wiring diagram supplied with the generator set. Install covers.

B. Measuring Generator Field Winding Insulation Resistance

Use 500 VDC hand cranked megger.

Test as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect the generator field leads from the (+) and (-) terminals located on the exciter rotating rectifier assembly heat sinks.
3. Connect megger ground lead onto either the generator shaft, fan, or drive hub.
4. Connect megger test lead onto either of the generator field lead wires. Make certain non-insulated lugs on field leads are not touching any generator parts.
5. Measure generator field winding insulation resistance. If the generator field winding insulation resistance is less than one megohm, determine cause of abnormally low insulation resistance. If due to wet windings, dry out generator as described in Section 9 in this manual.
6. Before operating the generator set, connect generator field leads onto exciter rotating rectifier heat sink (+) and (-) terminals (See Figure 3). Install covers.

C. Measuring Exciter Field Winding Insulation Resistance

Test using 500 VDC hand cranked megger as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Disconnect exciter field leads F+ and F- from the voltage regulator terminals F+ and F-.
3. Connect megger ground lead to the generator frame.
4. Connect megger test lead onto either exciter field lead F+ or exciter field lead F-. Make certain non-insulated ends on leads F- and F+ do not touch any metal parts.
5. Measure exciter field winding insulation resistance. If insulation resistance is less than one megohm, determine cause of abnormally low insulation resistance. If due to wet winding, dry out generator as described in Section 9 in this manual.
6. Before operating generator set, connect F+ lead wire onto voltage regulator terminal F+ and lead wire F-onto voltage regulator terminal F-. Install covers.

D. Measuring Exciter Armature Winding Insulation Resistance

Test using 500 VDC megger as follows:

1. Stop generator set and remove cover located on end of terminal box.
2. Using soldering gun, disconnect the three exciter armature lead wires from the exciter rotating rectifier assembly (see Figures 3 and 7).
3. Insulate non-insulated ends on two of the lead wires to prevent grounding during test.
4. Connect megger test lead onto the remaining exciter armature lead wire. Make certain non-insulated connection does not touch any metal part during test.
5. Connect megger ground lead onto either the generator shaft, fan, or drive hub.
6. Measure exciter armature winding insulation resistance. If insulation resistance is less than one megohm, determine cause of abnormally low insulation resistance.
7. Before operating generator set, solder exciter lead wires onto the exciter rotating rectifier assembly (see Figures 3 and 7).

SECTION 9
DRYING WINDINGS AND REMOVING AND INSTALLING PARTS

DRYING GENERATOR

An excessive accumulation of moisture on the generator windings can reduce the winding insulation resistance. The recommended stator winding insulation resistance test procedure and the minimum allowable insulation resistance is described in Section 8 in this manual.

Where moisture is present and test indicates insulation resistance does not exceed the minimum standard, thoroughly dry out the generator before operating the machine. The following are recommended drying methods.

A. Heat Enclosure

Remove the generator cover. Enclose the generator and insert heating units such as space heaters, lamps, or coils of steam pipe to raise the temperature. Leave a hole at the top of the enclosure to permit the escape of moisture. Temperature within the enclosure should not exceed 93 degrees C or 200 degrees F. The voltage regulator and any electronic components must be removed from the generator when using this method.

B. Forced Air

A portable forced air heater can be used to direct heat into the exciter end of the generator through openings in the endbell. Heat at point of entry should not exceed 93 degrees C or 200 degrees F.

C. Oven

Place the machine in a thermostat controlled oven and bake it at a temperature not to exceed 93 degrees C or 200 degrees F. The voltage regulator and any electronic component accessories must be removed from the generator when using this method.

REMOVING AND INSTALLING EXCITER ROTOR

The exciter rotor, Figure 2, consists of the exciter armature and the full-wave rotating rectifier assembly. The assembly mounts on an extension of the generator shaft that protrudes beyond the generator endbell. The exciter rotor assembly is held in place on the shaft by a rectangular key on the shaft and a bolt and washer on the end of the shaft. The inside surface on the exciter armature core is pushed against a raised shoulder on the generator shaft. The exciter has a small air gap with respect to that of the generator. For this reason the exciter rotor should be removed while transporting, assembling, or disassembling the generator and while coupling the generator to the prime mover.

A. Removing the Exciter Rotor

1. Remove cover located on end of generator terminal box.
2. Disconnect the generator field leads from the rotating rectifier (+) and (-) terminals.
3. Remove exciter retaining bolt from end of generator shaft.

NOTE: If exciter rotor cannot easily be removed by hand, a 1/4-20 bolt can be threaded into the tapped hole next to the exciter rotor. This action will push the exciter rotor off the shaft.

CAUTION

Do not pull on or strike the exciter armature windings.

4. Pull exciter rotor assembly off generator shaft. Pull rectangular key out of the keyway in shaft and keep it with the exciter rotor assembly.

B. Installing Exciter Rotor

1. Install rectangular key in keyway located in generator shaft.
2. Align keyway in the exciter armature core with the key and push exciter rotor onto shaft. DO NOT PUSH OR STRIKE WINDING OR RECTIFIER. MAKE SURE INSIDE EDGE ON ARMATURE CORE IS AGAINST RAISED SHOULDER ON SHAFT.
3. Install exciter retaining bolt on end of shaft. Torque 1/2 inch bolt to 60 foot-pounds.

4. Check exciter air gap. Air gap should not be less than that listed in Table 4. Check to make certain exciter armature core and the exciter field core are axially aligned.
5. Connect generator field leads onto rotating rectifier (+) and (-) terminals (refer to Figure 7).
6. Install cover on terminal box.

REMOVING AND INSTALLING TERMINAL BOX AND OUTBOARD ENDBELL

These parts must be removed to service or replace the bearing located at the exciter end of the generator.Be sure to follow the handling precautions described in Section 2 in this manual. Parts are shown on Figures 1 and 2.

A. Removing the Terminal Box and Outboard Endbell

1. Remove the side covers and the louvered end cover from the terminal box.
2. Disconnect incoming electrical cables and conduit. Disconnect stator leads.
3. Disconnect electrical wiring from voltage regulator and other controls mounted within the terminal box.
4. Remove the exciter rotor, comprised of the exciter armature and rotating rectifier assembly. Follow the steps given in procedure titled "Removing the Exciter Rotor."
5. Remove fiber wire retaining ring.
6. Remove parts that mount onto the back plate of the terminal box and the endbell.
7. Remove cover that surrounds the generator frame.
8. Place rotor support blocking in the generator air gap.
9. Remove bolts that mount the terminal box and the endbell onto the generator frame.
10. Remove terminal box.
11. On larger generators, attach hoist onto endbell. Take up slack but do not lift generator.
12. Pry endbell loose from pilot recess located in the frame endring.
13. Pull endbell straight back to position where bearing outer race is out of the bearing housing at the center of the endbell.
14. Remove endbell.
15. Some units may have circular fiber spacers located in the bearing housing section of the endbell. If this is the case, be sure to install spacers when reinstalling endbell.
16. Inspect and clean rust and dirt from the mounting face on endbell and the bearing housing. Remove any metal burrs.
17. Wipe a thin coat of grease in the bearing housing section of the endbell.

B. Installing Terminal Box and Outboard Endbell

During this procedure be sure to follow the handling precautions described in Section 2 in this manual. Refer to Figure 1 and the wiring diagram provided with the generator set.

1. Where generator was provided with circular spacers in the bearing housing section of the endbell, install the spacers.
2. Inspect to make certain bearing and mounting face on endbell is free of rust, dirt, and metal burrs.
3. Wipe thin coat of grease in bearing housing section in endbell.
4. Lift endbell into alignment with the bearing and carefully push bearing housing section on endbell over the outer race of the bearing.
5. Place endbell over end of shaft and turn endbell to position where lead wire hole in endbell aligns with lead wires. Pull stator leads through opening in the endbell. Make certain generator field leads are along wireway on shaft.
6. Push endbell bearing housing over the bearing outer race.
7. Mount terminal box and endbell onto the generator frame using hex head bolts and washers. Watch to make certain endbell fits evenly into pilot recess, and sequentially tighten bolts. Torque bolts according to recommended torque for SAE 5 cap screws given in Table 3.
8. Remove rotor support blocking from generator.
9. Install fiber wire retaining ring.
10. Install the exciter rotor as described in procedure titled "Installing Exciter Rotor."
11. Mount voltage regulator and controls.

12. Connect electrical wiring according to appropriate wiring diagram.
13. Before operating generator set, check to make certain unit is connected correctly and terminals are tight and insulated.
14. Remove tools and shop cloths.
15. Install covers and guards.

REMOVING AND INSTALLING DRIVE ENDBELL

The drive endbell encloses the driven end of the generator and also functions as the housing around the generator fan.This part must be removed to service or replace the bearing located at the driven end of the generator.

A. Removing Drive Endbell

1. On belt driven applications, remove drive belts and sheaves before removing endbell. Where generator is driven through flexible coupling, remove coupling and remove generator from the base before removing the drive endbell.
2. Loosen or remove cover that surrounds generator frame.
3. Place rotor support blocking in generator air gap.
4. Remove dripproof cover and screen from around endbell.
5. Remove bolts that mount the drive endbell onto the generator frame.
6. Pry endbell loose from pilot recess located in the frame endring.
7. Pull endbell straight back to position where bearing outer race is out of the bearing housing at the center of the endbell.
8. Remove endbell.
9. Remove air baffle located between the endbell and frame endring.
10. Some units may have circular fiber spacers located in the bearing housing section of the endbell. If this is the case, be sure to install spacers when reinstalling endbell.
11. Inspect and clean rust and dirt from the mounting face on endbell and the bearing housing. Remove any metal burrs.
12. Wipe a thin coat of grease in the bearing housing section of the endbell.

B. Installing Drive Endbell

During this procedure be sure to follow the handling precautions described in Section 2 in this manual. Refer to Figure 1 and the wiring diagram provided with the generator set.

1. Where generator was provided with circular spacers in the bearing housing section of the endbell, install the spacers.
2. Inspect to make certain bearing housing and mounting face on endbell is free of rust, dirt, and metal burrs.
3. Wipe thin coat of grease in bearing housing section in endbell.
4. Install air baffle.
5. Lift endbell into alignment with bearing and carefully push endbell over bearing.
6. Turn air baffle and endbell to position where bolt holes align with tapped holes in frame endring.
7. Sequentially tighten bolts that mount endbell onto the frame endring. Make certain endbell fits evenly into the pilot recess located in frame endring. Torque bolts. Refer to recommended torque for SAE 5 cap screws given in Table 3.
8. Remove support blocking from the generator air gap.
9. Remove tools and shop cloths.
10. Install generator covers.
11. Mount and align generator. Refer to procedures given in Section 3.

REMOVING AND INSTALLING BEARING

If the bearing(s) need to be removed for any reason, always install a new bearing. Remove and install bearing according to the general procedure that follows. Be sure to follow the handling precautions described in Section 2 in this manual.

1. Remove appropriate endbell.
   a. To replace drive bearing first remove drive endbell according to "Removing and Installing Drive Endbell" procedure.
   b. To replace outboard bearing, first remove exciter rotor, terminal box and endbell as described in "Removing and Installing Exciter Rotor" and "Removing and Installing Terminal Box and Outboard Endbell" procedures.
2. Remove bearing with suitable puller.
3. Apply a thin coat of clean lubricating oil or anti-seize lubricant to the pressure fit on the rotor shaft.
4. Heat the new bearing in an oven to a maximum temperature of 225°F.

CAUTION

Under no circumstances should pressure be applied to the outer race of the bearing, as permanent bearing damage could result.

CAUTION

Before installing bearing located at exciter end of generator, make sure generator field leads are in place in the wireway machined along generator shaft.

CAUTION

When handling heated bearing, wear protective clothing and gloves.

NOTE: **The bearing should slide on the shaft and be seated without excessive force. If the bearing binds on the shaft before being fully seated, a piece of tubing slightly larger than the shaft diameter can be placed over the shaft and the bearing can be slid in place by tapping lightly on end of tubing with a soft mallet. Care must be taken to ensure pressure is applied to the inner race only.**

5. Wearing protective gloves, start bearing evenly onto machined bearing journal section of the generator shaft.
6. Before bearing is allowed to cool, push bearing into place on shaft using a metal or fiber pipe with I.D. larger than the shaft. When properly installed, the bearing inner race will be against the step on the shaft.
7. Allow bearing to cool.
8. Install endbell. Refer to appropriate procedure.
   a. Where drive bearing was replaced follow "Installing Drive Endbell" procedure.
   b. Where outboard bearing was replaced follow "Installing Terminal Box and Outboard Endbell" procedure.
9. Where outboard bearing was replaced, install exciter rotor as given in the "Installing Exciter Rotor" procedure.
10. Remove rotor support blocking from generator air gap.
11. Where drive end bearing was replaced, mount, couple, and align generator as given in Section 3.
12. Remove tools and shop cloths.
13. Install covers.

REMOVING AND INSTALLING GENERATOR FAN

The fan consists of two half-sections bolted together. Access to the fan bolts is attained by removing the screen and dripproof shield that surrounds the drive endbell. In general, it will be necessary to remove the fan or loosen the fan bolts only when one of the following repair procedures is required:

1. Maintenance on fan blades or hub.
2. Removal of generator rotor through exciter end of generator.
3. Installation of original fan on a replacement rotor.

A. Removing Fan

NOTE: Do not remove fan or loosen fan blades unless it is absolutely necessary. Refer to preceding description.

1. Remove covers that surround generator frame and drive endbell.
2. Measure and record one or both of the following dimensions before loosening fan bolts.
   a. Measure from the fan blades to the air baffle.
   b. Measure from the fan hub to the drive bearing.

NOTE: When installing fan, position the fan on the shaft according to distance measured during step 2.

3. Place support blocking in generator air gap, remove coupling and remove drive endbell as given in "Removing and Installing Drive Endbell" instructions.
4. Loosen fan bolts and remove fan.

B. Installing Fan

1. Position fan on generator shaft at distance measured during step 2 of preceding "Removing Fan" instructions.
2. Torque fan bolts according to recommended torque fan SAE 5 cap screws.

REMOVING AND INSTALLING GENERATOR ROTOR

Rotor removal requires removal of the following parts:

1. Exciter rotor
2. Outboard endbell and terminal box
3. Drive endbell
4. Drive coupling or on belted generator sets the drive sheaves and belts

NOTE: On flexible coupled generator sets, unless there is sufficient space for removing the rotor through the outboard end of the generator, it will be necessary to remove the generator from the base.

Where rotor will be removed from drive end, the generator fan should be left in place on the rotor. Rotor removal through the outboard or exciter end requires the fan to be removed from the shaft before attempting to slide the rotor out of the stator.

A. Removing Rotor

Determine direction rotor will be removed from stator. Refer to preceding note and items 1 through 4.

1. Remove required parts according to the appropriate instructions given in preceding parts of Section 9.
2. Where rotor will be removed from drive end of generator, obtain a burr free metal pipe that is as long as the generator stator and has an I.D. slightly larger than the shaft. Slide the pipe over the portion of the generator shaft that mounts the exciter rotor.
3. Where rotor will be removed from exciter end of generator, obtain a burr free metal pipe that is as long as the generator stator and has an I.D. slightly larger than the shaft. Slide the pipe over the driven end of the generator shaft.

4. Follow either step a or b.
   a. Install portable jack under the pipe and another under the shaft at the opposite end.
   b. Wrap cable around the pipe and attach to an overhead hoist. Wrap a cable about the generator shaft at the opposite end of generator and attach cable to another hoist.

CAUTION

While removing and installing rotor, visually check to make certain that windings do not strike or rub against parts in the generator.

5. Carefully lift both ends of generator rotor to position where air gap exists around entire O.D. of rotor core
   structure.
6. Move rotor out of stator by moving the jacks or hoists. Visually check to make certain that air gap is maintained and windings do not strike or rub against other parts of the generator.
7. Place rotor on support blocks.

B. Installing Rotor

1. Lift rotor into alignment with the stator.
2. Install pipe through stator and onto end of rotor shaft. See steps 2 and 3 of preceding "Removing Rotor" instructions.
3. Attach cables and hoists or use jacks as described in step 4 of "Removing Rotor" procedure.
4. Carefully move rotor into stator watching to make sure air gap is maintained and windings do not strike or rub on generator parts.
5. Install rotor support blocks in air gap.
6. Lower rotor onto rotor support blocking. Then remove cables and hoists or jacks.
7. If fan was removed, install fan.
8. Install drive endbell as described in "Installing Drive Endbell" procedure.
9. Install outboard endbell and terminal box as described in "Installing Terminal Box and Outboard Endbell"procedure.
10. Measure to make certain fan is correct distance from air baffle. Refer to "Installing Fan" procedure. Torque fan bolts in accordance with recommended torque for SAE 5 cap screws given in Table 3.
11. Install exciter rotor as given in the "Installing Exciter Rotor" procedure.
12. Remove support blocking from generator air gap.
13. Turn generator rotor slowly by hand. Visually check to make certain rotating parts do not rub on stationary parts.
14. Mount, couple and align generator. Refer to procedures given in Section 3.
15. Remove tools and shop cloths.
16. Connect electrical wiring.
17. Install covers.

SECTION 10
FIGURES AND TABLES

GENERAL

The drawings, electrical schematics, and tables contained in this section are included to aid in the installation and maintenance of this equipment. The overall electrical connection diagram supplied with the generator set should be followed when connecting the stator lead wires, voltage regulator, and any other operating controls provided with this unit.

Table 1
Generator Voltage - Standard Kamag Generators

Connection (See Note)	Voltage Range (By Adjustment of voltage control rheostat)	
	50 Hertz	60 Hertz
3 Phase series wye (Phase-to-Phase)	340 to 400	408 to 490
3 Phase parallel wye (Phase-to-Phase)	170 to 200	204 to 245
3 Phase series delta (Phase-to-Phase)	196 to 230	236 to 283
Single Phase 3 wire (Line-to-Line)	196-230	236 to 283

NOTE: Phase-to-neutral voltage for 3-phase wye connections are 58% of line-to-line voltages listed. Line-to-neutral voltage for 3 wire single phase is one-half the line-to-line voltage listed.

Table 2
Minimum Air Gap for Kato Brushless Exciter

Exciter Rotor (Armature) Diameter (in inches)	Minimum Air Gap (in inches)
5 3/4	0.014
9 7/8	0.014
12/ 1/2	0.018
16 1/4	0.035

WARRANTY

Kato Engineering warrants that its products will perform as specified in bonafide quotations or Kato publications, providing such products are properly installed, properly cared for, and properly operated under normal environmental conditions.

Standard products manufactured by Kato Engineering are warranted to be free from defects in workmanship and material for a period of one year in operation or 18 months from date of shipment, and any products which are defective in workmanship or material will be repaired or replaced at the option of Kato Engineering. Final determination as to whether a product is actually defective rests with Kato Engineering. The obligation of Kato Engineering hereunder shall be limited solely to repair and replacement at its factory, of products that fall within the foregoing limitations and shall be conditioned upon receipt by Kato Engineering of written notice within the warranty period of any alleged defects or deficiency. No products shall be returned to Kato Engineering without its prior consent. In no case will Kato Engineering accept shipping charges incurred either through return of defective items to its factory or return of repaired or replacement items to the user. Kato Engineering cannot assume responsibility or accept invoices for unauthorized repairs to its components even though defective. In the case of components, parts or units purchased by Kato Engineering the obligation of Kato Engineering shall not exceed the settlement that it is able to obtain from the supplier thereof.

The life of the products of Kato Engineering depends to a large extent upon the type of usage. Kato Engineering makes no warranty as to period of service nor as to fitness of its products for specific applications by the buyer. In no event will Kato Engineering be liable for consequential or incidental damages or any expense incurred by the Buyer due to use or sale of products sold by Kato Engineering.

The foregoing warranty is exclusive and in lieu of all other warranties expressed or implied, including but not limited to any warranty of merchantability or of fitness for a particular purpose.

This Warranty does not apply to experimental or developmental products.

SAFETY

PLEASE REMEMBER SAFETY FIRST. If you are not sure of the instructions or procedures, seek qualified help before continuing.

This service manual emphasizes the safety precautions necessary during the installation, operation, and maintenance of your generator.

Each section has caution and warning messages. These messages are for your safety and the safety of the equipment involved. If any of the cautions or warnings is not readily understood, seek clarification from qualified personnel before proceeding.

Before any service work is done, disconnect all power sources and, where appropriate, lock out all controls, to prevent an unexpected start-up of the generator set. Proper grounding in compliance with local and national electrical codes must be provided. These safety precautions are necessary to prevent potential serious personal injury, or even death.

The hazards associated with lifting or moving the generator are pointed out in the installation and service sections; incorrect lifting or moving can result in personal injury or property damage.

Whenever the generator is running, always assume and proceed as if voltage is present. Residual voltage is present at the generator leads and at the regulator panel connections, even with the regulator fuse removed. Caution must be observed, or serious personal injury or death can result.

Whenever solvents, cleaners, or flammable liquids are present, adequate ventilation must be available to avoid fire, explosion, and health hazards. Always avoid breathing vapors and use suitable personal protective equipment to prevent personal injuries. (Such as eyes, face, and hand protection.)

This manual is not intended to be a substitute for properly trained personnel. Only qualified trained people should attempt repairs. The cautions and warnings point out known conditions that are potentially dangerous. Each installation will create its own set of circumstances. No manual can cover every possible situation.

When in doubt, ask. Don’t be embarrassed to ask, “dumb questions”. Remember that dumb questions are much easier to handle than dumb mistakes.

GENERAL INFORMATION

MECHANICAL DESIGN

General

All single and two bearing units are manufactured with cast iron end brackets and adapters, and fabricated steel frames. Flexible drive discs and SAE adapters are machined to SAE standards. Pre-lubricated, regreasable, shielded ball bearings are used on MagnaMAX generators. Standard units are fully guarded. Drip proof shields are available as an option.

Conduit Box

The large end mounted conduit box is constructed of formed sheet steel that will allow the addition of top mounted control packages. Refer to Katolight for top mounted controls of more than 240 lbs. There is ample room inside the conduit box for a circuit breaker (through 800A Frame) and other options. The conduit box cover properly directs outside ventilating air through the generator.

MagnaMAX Unirotor™ Construction

An aluminum die cast rotor core affords high mechanical integrity and low vibration at operating speeds. Amortisseur winding and coil supports are die cast as an integral part of the rotor. Laminations are 4-pole, one piece laminations which are shrunk fit and keyed to the shaft. No dovetails, cross bolts or other pole to shaft connecting devices are used. The cast unidirectional aluminum alloy ventilation fan provides even air distribution to maximize cooling and generator efficiency.

Adapters and Drive Discs

All single bearing units are available with several adapters and drive disc arrangements. These can be shipped to order or can be changed in the field with standard shop tools. When changing flexible drive discs, spacers are used between the discs and the cast iron hub to maintain SAE standard dimensions.

ELECTRICAL DESIGN

All standard products have 2/3 pitch main windings to eliminate the third harmonic. This serves to lower operating temperatures, give lower harmonic content and better waveform, and extend the overall life of the generator.

Temperature Rise

All ratings and frame sizes are based on NEMA and CSA Class F and Class H temperature rises on both the rotor and stator windings. Ratings for British, German, French, IEC and all popular marine agencies are available.

Standby Generator Ratings

Synchronous generators used on emergency backup power can have temperature rises up to 25°C above those for continuous operation. (NEMA MG1 -22.40 and MG 1-22.84).

Premium Insulation System

All MagnaMAX generators are built with Class H or better insulation materials. All standard generators are suitable for continuous duty at Class F temperature rise and will give equivalent or better winding life expectancy to generators supplied with Class A or B insulation systems operated within their temperature limits. The varnishes and epoxies used are synthetic, non-hygroscopic. Multiple dip and bake cycles of the main winding, plus a final coat of epoxy, make the standard winding moisture and fungus resistant. The MagnaMAX rotor is wet wound with thermo-setting epoxy applied between each layer, plus a final coating of epoxy for moisture and abrasion resistance.

MagnaMAX generators can be ordered with an epoxy vacuum pressure impregnated insulation system as an option. (MagnaMAX generators with form wound coils include VPI as standard.)

Power Factor

All standard generators are designed for operation at rated kVA at 0.8 lagging power factor but can be operated at rated kVA over the 0.8 to 1 .0 power factor range.

MagnaMAX Voltage Regulator

The standard voltage regulator is a fully encapsulated, static types with a solid state build up circuit. Standard features include 3-phase RMS sensing, paralleling, adjustable under frequency protection, and over excitation protection. The regulator meets EMI suppression to Mil Std-461B, part 9. An optional feature is adjustable armature current limiting. See the regulator manual for more information.

HOW TO READ A MODEL NUMBER

It is extremely important to properly identify the machine when requesting parts or service. Always have the generator model number and serial number when requesting information from the factory. We cannot help you without this information.

INSTALLATION

RECEIVING YOUR MAGNAMAX GENERATOR

Upon receipt of the generator, it is recommended that it be carefully examined for possible damage incurred in shipment. The generator was given to the Freight Company in good condition, and they are responsible for the product from our dock to yours. Any damage should be noted on the freight bill before accepting the shipment. Claims for damages must be promptly filed with the Freight Company.

UNPACKING AND HANDLING

Read all instruction cards carefully. When lifting, attach an overhead crane to the lifting lugs on the generator frame. Apply lifting forces in a vertical direction.

WARNING
THE LIFTING LUGS ON THE GENERATOR ARE DESIGNED TO SUPPORT THE GENERATOR ONLY. DO NOT LIFT COMPLETE GENERATOR SET BY MEANS OF LIFTING DEVICES ON THE GENERATOR. PERSONAL INJURY OR QUIPMENT DAMAGE MAY OCCUR.

STORAGE

In the event that the generator is not to be installed on the prime mover immediately, it is recommended that it be stored in a clean, dry area that is not subject to rapid changes in temperature and humidity. See "STORAGE INSTRUCTIONS" for more information.

PREPARATION FOR USE

Although the generator is carefully inspected and tested in operation before it leaves the factory, it is recommended the unit be thoroughly inspected. The insulation on the wire should be inspected and all bolts should be checked for tightness.

Remove all shipping tapes, bags, blocks, and skids, which are used to prevent vibration and rotor movement during shipment. Dry, low-pressure compressed air of approximately 30 PSI (206 KPA) can be used to blow out the interior of the generator. In the case of two bearing machines, it is possible to turn the rotor by hand to make sure that it rotates smoothly without binding.

If the machine has been in storage for a year or longer it is recommended that it be lubricated according to the lubrication instructions and chart supplied in the maintenance section.
If the machine has been exposed to damp, humid conditions the insulation resistance should be checked. Refer to the instructions supplied in this manual.

GENERATOR MOUNTING - SINGLE BEARING

Single bearing generators are provided with an SAE flywheel adapter and flexible drive discs. Very close tolerances are maintained in the manufacture of the generator so that the alignment procedure is extremely simple. A coupling hub of nodular iron is shrunk on the shaft and special steel drive

discs are bolted to the hub. Holes are provided in the periphery of the coupling disc, which correspond to tapped holes in the flywheel. The outside diameter of the discs fits in a rabbet in the flywheel so that concentricity is assured in all cases.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFITNG OR FOR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE

CAUTION: GRADE 8 CAPSCREWS OR GRADE 8 PLACE-BOLTS AND HARDENED WASHERS ARE REC-OMMENDED TO MOUNT THE DRIVE DISCS TO THE FLYWHEEL.DO NOT USE HELICAL OR OTHER LOCKING DEVICES UNLESS APPROVED.

The SAE adapter and the flywheel housing are designed to match each other with no further alignment necessary. Shims may be necessary under the feet of the generator to insure a solid mounting. See THE SERVICE SECTION for more information.

GENERATOR MOUNTING-TWO BEARING

Two bearing generators are provided with a shaft extension and key way. For direct-coupled sets the assembler furnishes a flexible coupling which is installed between the driver and the generator shaft.

IMPORTANT: Aligning the two machines as accurately as possible will reduce vibration, increase-bearing life, and insures minimum coupling wear. It may be necessary to shim the generator feet for proper support and alignment. Consult the coupling manufacturer's instructions for alignment specifications and procedures.

BELT DRIVE

Please refer to Katolight for applications involving belt driven installations.

ENVIRONMENTAL CONCERNS

Dirt, moisture, heat, and vibration are enemies of electrical equipment. The ambient temperature should not exceed the value shown on the generator nameplate. Generators for outdoor application should be protected from the elements by housings with proper openings for ventilation. This protection should be designed to prevent the direct contact of wind driven rain, snow, or dust with the generator. In moist or humid areas, such as the Tropics and marine serv-ice, additional protection is recommended. Although the standard windings are humidity and moisture resistant, special insulation and accessories such as space heaters can increase generator life. In extremely dirty and dusty environments a means of providing filtered cooling air to the generator is recommended. Please refer to Katolight for filter kits that are available.

ELECTRICAL CONNECTIONS

The generator conduit box construction allows conduit to enter the top, bottom, or either side of the box. A hole-saw or any suitable tool can be used to provide for the conduit entrance. Protect the interior of the generator from shavings when drilling or sawing. An approved connector must be used in conjunction with the conduit.

To minimize the transmission of vibration, it is essential that flexible conduit be used for all electrical cable entrance to the generator.

Refer to the connection diagram supplied with the generator and / or the proper diagrams shown in this section. Install all intercomponent and external wiring in accordance with the regulations of the national and local electrical codes. Clean all contact surfaces to assure good electrical bonding with the generator lugs or bus bars. Use heavy-duty terminal lugs or good quality clamps for making all connections. Insulate all connections in accordance with national and local regulations.

Be sure the generator frame is grounded to all the other components of the system with a ground wire in accordance with national and local regulations.

GENERATOR LEAD CONNECTIONS

The electrical connections in the conduit box should be made in accordance with the appropriate “connection diagram.” Use the diagram appropriate for the number of leads and voltage range required. Refer to the drawings supplied with the generator and to drawings in this section.

The final voltage setting is established within the selected range by an adjustment of the voltage regulator.

CAUTION: SOME GENERATORS HAVE MULTIPLE, IDENTICALLY MARKED, CABLES FOR EACH LEAD. CONNECT ALL IDENTICALLY MARKED CABLES TOGETHER WHEN MAKING CONNECTIONS.

PARALLELING OPERATIONS

MagnaMAX generators come standard with amortisseur windings die cast as an integral part of the rotor. This exclusive, Unirotor™, construction makes all MagnaMAX generators suitable for paralleling operations when the proper control equipment is added. Paralleling with other generator sets and / or with the utility power grid offers a number of advantages. Multiple unit installations increase power capacity; they can be added or removed from the line depending on the load requirements; they can be better maintained and repaired (since single source breakdown would mean total loss of power), and they often provide more reliable, efficient, and economical operation.

Successful parallel operation means that the generators deliver power to the external system without delivering power to each other, or accepting power from the load bus or power grid. Additional equipment is necessary to insure safe and successful operation.

PRIME MOVER

The prime mover provides the speed and torque which will be necessary to keep the machines in synchronized operation. A governor controls the prime mover's speed. The governor will directly control the watt or kW output and frequency of the unit. The governor must have special paralleling provisions to permit parallel operation with the other machines.

VOLTAGE REGULATOR

The voltage regulator controls the generator output voltage and the reactive power supplied by the generator. When two or more ac generators operate in parallel, the voltage regulator must have paralleling provisions (either internally or external to the regulator) to control the reactive or VAR load while it is in parallel operation. A separate paralleling current transformer is required to sense the reactive current and signal the voltage regulator. This additional paralleling circuitry is absolutely necessary to control the reactive current flowing between the generator sets.

SWITCHGEAR

There are additional relays and breaker controls that are necessary to insure safe, trouble free operation of paralleled units. Reverse power relays monitor the direction of power flow to insure that the generator is delivering power, not accepting it. These power relays control breakers, which are a means of connecting and disconnecting the generator from the load. The total system can include over-voltage, over-current protection, under frequency protection, power factor correction provision and a variety of associated control equipment from manual switchgear to microprocessors. The amount of control gear and level of sophistication will be determined by the needs and requirements of the particular application.

PARALLELING BASICS

The following points are basic criteria which must be met before two units can be paralleled. **THIS IS NOT MEANT TO BE SPECIFIC INSTRUCTIONS FOR PARALLELING OPERATION.**

1. Additional paralleling circuitry
   - A. Voltage regulator-paralleling provisions
   - B. Paralleling current transformer(s)
   - C. Paralleling provisions on governor controls
   - D. Switchgear

2. The voltage and frequency must be the same for all sets with voltages in phase.

3. The voltage regulation characteristics of the individual generators should be similar.

4. The generators must have the same phase rotation.

5.The driving engines should have the same speed regulation characteristics and the governors should be adjusted to give the same speed regulation.

Before operating generator sets in parallel, each set should be checked by starting, operating, and adjusting the sets as individual units before attempting paralleling.

REACTIVE LOAD CONTROL

When two identical generators are operating together in parallel and an unbalance occurs in field excitation, circulating currents begin to flow between the generators. This current will appear as a lagging power factor or inductive load to the highly excited generator, and as a leading power factor or capacitive load to the generator with the lower field current. This is known as the reactive circulating current and there are two methods of controlling it in parallel operation:

1. Reactive droop compensation. (Formerly known as parallel droop compensation.) The bus voltage droops, or decreases, as the reactive lagging power factor load is increased.

2. Reactive differential compensation. (Formerly known as cross current compensation.) The reactive differential compensation circuit allows parallel generators to share reactive loads with no decrease or droop in generator voltage.

The circuit must meet the following criteria:

A. All paralleling current transformers for all the generators being paralleled must be included in the secondary interconnection loop.

B. When different size generators are paralleled all paralleling current transformers must have the same proportional ratios that give approximately the same secondary current.

C. Voltage regulator paralleling circuitry must be the same.

D. Current transformer secondary and the generator lines must be isolated electrically.

E. It is also desirable to have an auxiliary contact on the main generator breaker to short the parallel CT secondary when that breaker is open (not connected to the load bus).

Because of the above criteria, reactive differential compensation cannot be used when paralleling with the utility power grid. There is no limit, however, in the number of generators that can be included in this type of circuit.

PARALLELING CIRCUITRY

Because of the number of variables involved in paralleling generator sets, every installation will have its own circuitry and methods or procedure of bringing paralleled units on line. There are numerous ways of connecting paralleled units and an almost unlimited variety of applications and associated equipment.

When parallel operation is desired, it is important that the control manufacturer, the generator manufacturer, and the systems engineer work together to insure the proper selection of all components. Please refer to Katolight for application assistance.

THYRISTOR OR SCR LOADING

Solid state electronic control devices which utilize thyristors or SCR firing circuits (such as variable frequency induction motor controls, precision motor speed controls, no-break powered battery chargers, etc.) can introduce high frequency harmonics which adversely affect or destroy the normal waveform of the generator. This creates additional heat in the generator stator and rotor, and can cause overheating. These devices can and do present problems to non-utility power generating equipment or any limited power bus system. The problems that can occur are not limited to the generator itself, but can effect the solid state control device, the equipment it controls, other associated loads, monitoring devices or a number of combinations over the entire system.

MagnaMAX generators can supply power to thyristor or SCR loads when properly applied. The standard voltage regulator is PMG powered and senses 3 phase RMS voltages for maximum stability against severely distorted waveforms. SCR type applications such as cranes, shovels, etc., require special consideration of the generator insulation system due to greater dielectric stress and severe environmental conditions. It is important that the control manufacturer, the generator manufacturer, and the systems engineer work together to insure the proper selection of all components. Please refer to Katolight for application assistance.

OPERATION

PRE-START INSPECTION

Before operating the generator for the first time, the following checks are recommended.

1. A visual inspection should be made to check for any loose parts, connections, or foreign materials

2. Check for clearance in the generator and exciter air gap. Be sure the generator set turns over freely. Bar the generator over by hand at least 2 revolutions to be sure there is no interference.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFITNG OR FOR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE

3. Check all wiring against the proper connection diagrams and make sure all connections are properly insulated. Support and tie leads to keep them from being damaged by rotating parts or by chafing on sharp corners.

4. Be sure the equipment is properly grounded.

5. Inspect for any remaining packing materials and remove any loose debris, building materials, rags, etc. that could be drawn into the generator.

6. Check fasteners for tightness.

7. Check to be sure no tools or other hardware have been left inside or near the machine.

8. Install and check to be sure all covers and guards are in place and secure.

WARNING
RESIDUAL VOLTAGE IS PRESENT AT THE GENERATOR LEADS AND AT THE REULATOR PANEL CONNECTIONS EVEN WITH THE REGULATOR FUSE REMOVED. CAUTION MUST BE OBSERVED OR SERIOUS PERSONAL INJURY OR DEATH CAN RESULT.

STARTING-UP THE GENERATOR

The following procedure should be followed for starting-up the generator for the first time:

1.The generator output must be disconnected from the load. Be certain that the main circuit breaker is open.

2.Disable the voltage regulator by removing the fuse.

WARNING
DO NOT OVERSPEED THE GENERATOR. EXCESSIVE CENTRIFUGAL FORCES COULD DAMAGE THE ROTATING FIELDS. BE PREPARED FOR AN EMERGENCY SHUTDOWN.

3.Follow the manufacturer's instructions and start the prime mover. Check the speed and adjust to the RPM shown on the generator nameplate.

4. Replace the regulator fuse and adjust the voltage to the required. Check all line to line and line to neutral voltages to be sure they are correct and balanced. If the voltages are not correct shut down immediately and recheck all connections.

5. Close the main circuit breaker and apply the load.

6. Monitor the generator output current to verify it is at or below nameplate amps.

7. Adjust engine speed at full load to 1800 rpm for 60 hertz, 1500 rpm for 50 hertz. (Refer to prime mover/governor instruction manuals.)

8. Before stopping the engine, remove the load by tripping the main circuit breaker.

FIELD FLASHING

The standard MagnaMAX generator is supplied with a PMG (permanent magnet generator). **It will never require field flashing.** In rare cases where a special generator may be furnished without a PMG, refer to the factory for more detailed information. Include the complete generator model and serial number.

VOLTAGE ADJUSTMENTS

The voltage regulator controls the generator output voltage. There is a cover to access the control panel on the side of the generator conduit box

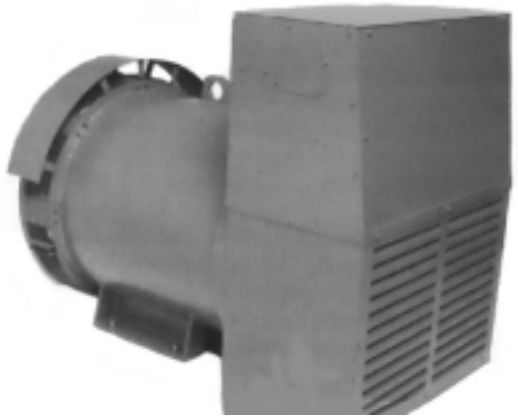

Figure 4-1

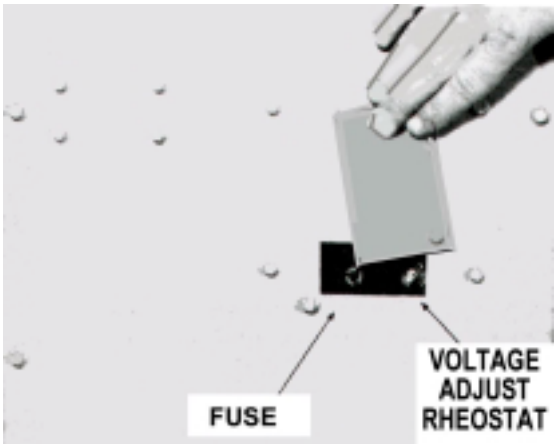

Figure 4-2 Regulator Access

Refer to the regulator manual for detailed information. In cases where special or remote mounted regulators are used, refer to instructions supplied by the generator set assembler and to the voltage regulator manual.

OTHER ADJUSTMENTS

Depending upon application, adjustments to other protective and control gear may be required. Refer to instructions provided by the by the supplier of the generator set.

The standard MagnaMAX voltage regulator also has many protective and control circuits. It is imperative that the set up instructions for any regulator supplied be followed.

MAINTENANCE

GENERAL INFORMATION

Dirt, heat, moisture, and vibration are common enemies of a generator. Keeping the generator clean and dry, maintaining proper alignment of the generator and its prime mover, and preventing overloads will result in efficient operation and long life.

Generators that are outdoors should be protected from the elements by suitable houses or enclosures.

Dirt and dust will conduct electricity between points of different electrical potential. Moisture will aggravate the problem further. Insulation system failure can result if corrective action is not taken. Measuring insulation resistance can test the condition of the insulation system.
(See Generator Testing.).

Insulation resistance should be checked when putting the generator into service after it has been in storage and anytime contamination by moisture and dirt is suspected. Normally, moisture buildup is not a problem while the generator is running, since heat produced internally will tend to keep it dry but can collect in the generator when it is shut down. The problem will be worse in humid environments or in areas where extreme temperature changes cause condensation (dew) to form inside the generator. Space heaters, air filters, and premium insulation systems, such as our VPI process, should be considered in difficult environments.

Accumulations of dust and dirt not only contribute to insulation breakdown, but they can also increase temperature by restricting the dissipation of heat. Materials such as talc, lint, rock dust, or cement dust may obstruct the ventilation.

The most harmful types of foreign materials include carbon black, metallic dust and similar substances that not only impede ventilation, but also form a conductive film over the insulation, increasing the possibility of insulation failure.

Machines operating in dirty places should be disassembled and cleaned periodically.

AIR INTAKE AND EXHAUST

Check the area around the air intake and exhaust openings to be sure they are unobstructed.

.

Figure 5-1

ELECTRICAL CONNECTIONS, WINDINGS

Inspect for loose or contaminated connections Check wires for cracked or frayed insulation. Tighten connections and replace defective or oil soaked insulation.

If inspection shows that varnish coatings on the windings have deteriorated, they should be coated with insulating varnish. Please refer to Katolight for insulation system requirements.

LUBRICATION

All generators are lubricated before leaving the factory and are ready for operation. As a general rule, bearings should be re-lubricated annually or at the indicated intervals in table 5-3, whichever occur first.

Unusually severe operating conditions, such as high ambient or dusty environments, require more frequent lubrication (every six months or one half the table intervals, whichever occurs first).

Use Chevron SRI or equivalent anti-friction type high quality, grease with a lubrication temperature' range of -22° to +350° F (-30° to +175° C)

To add or renew grease, proceed as follows:

1. Stop unit.

2. Wipe the grease plugs and surrounding parts to insure they are clean.

3. Remove both the fill and drain plugs.
See figure 5-2

4. Insert 1/8" N.P.T. grease fitting in fill pipe.

5. Free the drain holes of any hard grease, using a piece of wire it necessary.

6. Using a low-pressure grease gun, add grease according to the amounts in table 5-3.

7. Start unit with drain plug removed - fill pipe may be open or closed. Allow unit to run 15 minutes to allow excess grease to drain.

8. Stop unit, wipe off any drained grease, and replace filler and drain plugs.

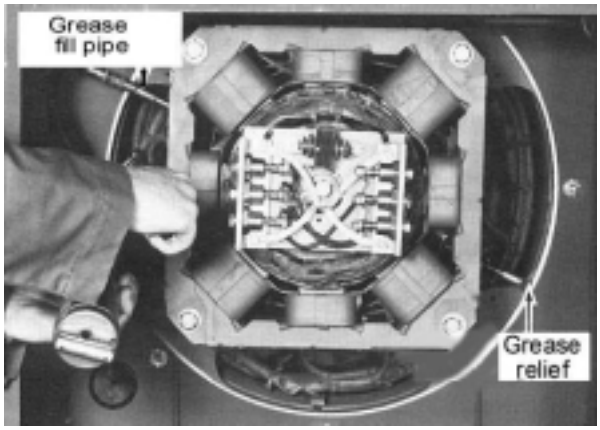

Figure 5-2

The amount of grease added is very important! Only enough grease should be added to replace the grease used by the bearing.

CAUTION: TOO MUCH GREASE CAN BE AS HARMFUL AS INSUFFICIENT GREASE. USE THE PROPER AMOUNT.

Type	Frame Size	Bearing Size	Amount of Grease			Intervals --- Max. hours or annually	
			Ounces	Cubic Inches	Teaspoons	60 Hz	50 Hz
Single Bearing Units	431,432, 433	314	1.2	2.1	7.0	6500	8400
	571,572, 573, 574	316	1.5	2.6	8.3	5600	7200
	741, 742, 743,744	322	2.4	4.2	14.0	3000	4500
Double Bearing Units	431,432	318	1.7	3.0	9.9	4600	6200
	571, 572, 573, 574	318	1.7	3.0	9.9	4600	6200
	741, 742, 743, 744	322	2.4	4.2	14.0	3000	4500

TABLE 5-3

During an overhaul, the grease reservoir should b thoroughly cleaned and new grease added. The reservoir should be 1/3 to 1/2 filled with new grease

DRYING ELECTRICAL INSULATION

Electrical components must be dried before placing in operation if tests indicate that the insulation resistance is below a safe value. (See Generator testing for test procedure.)

Machines that have been idle for sometime in unheated and damp locations, may have absorbed moisture. Sudden changes in temperature can cause condensation or the generator may have become wet by accident. Windings should be dried out thoroughly before being put into service. The following are recommended drying methods.

Space Heaters

Electric space heaters can be installed inside of the generator. When energized (from a power source other than the generator) they will heat and dry the inside of the generator. If an alternate source of electricity is not available, enclose the generator with a covering and insert heating units to raise the temperature 15-18 degrees F (8-10 degrees C) above the temperature outside of the enclosure. Leave a hole at the top of the enclosure to permit the escape of moisture.

Oven

Place the machine in an oven and bake it at a temperature not to exceed 194 F (90°C). The voltage regulator and any electronic component accessories must be removed from the generator when using this method.

Forced Air

A portable forced air heater can be used by directing heat into the air intake (conduit box) and running the generator with no load and without excitation (this can be accomplished by removing the regulator fuse). Heat at point of entry should not exceed 150° F (66° C).

"Short Circuit" Method

Using this method can dry out the generator quickly and thoroughly.

WARNING:
BE SURE THAT ALL OF THE FOLLOWING STEPS ARE PERFORMED AND ALL PRECAUTIONS TAKEN AS PERSONAL INJURY OR SERIOUS DAMAGE TO THE GENERATOR COULD RESULT.

1. Disconnect exciter leads Fl and F2 from the regulator.

2. Connect a battery or other dc power source approximately 20-35 volts to the exciter lead Fl and F2. An adjustable voltage source desirable, however, a rheostat (rated approximately 2 amps) in series with the dc power source will work.

3. Short circuit the generator output lead wires to each other (L1 to L2 to L3). If using jumpers, be sure they are large enough to carry full load amps.

4. Start the generator and measure the current through the output leads with a clip-on ammeter.

5. Adjust the voltage source to produce approximately 80% of the rated ac nameplate current but in no case exceed nameplate amps. If a adjustable source is not available and current is excessive, use a lower dc source voltage or larger resistor in series with the source.

Running time will be determined by the amount of moisture present in the machine. Insulation resistance checks should be taken every one to four hours until a fairly constant value obtained. (See section - Generator testing for instructions on measuring insulation resistance.)

6. After the generator is dry and the insulation resistance is brought up to specification remove the short circuit from the line lead disconnect the dc source and reconnect the F and F2 leads at the regulator. Be sure all connections are tight and correct before attempting to run the generator.

CLEANING METHODS

When electrical components get dirty, the insulation must be cleaned. There are a number of acceptable methods for cleaning the generator, each of which will necessitate disassembly of the unit. The kind of dirt, and when the unit must be returned to service will determine the method of cleaning. Drying after cleaning is necessary.

Whenever the generator is disassembled, the windings should be given a thorough inspection and the insulation cleaned, if necessary. The inspection should include the connection of the windings, insulation, and varnish coverage. Check the winding ties and coil supports. Look for any signs of coil movement or looseness and repair as required.

An electric motor repair shop in your area can normally assist with the proper cleaning of the generator windings. They may also be experienced in special problems (such as seacoast, marine, oilrig, mining, etc.) that may be peculiar to a certain area.

Solvents

A solvent is usually required to remove accumulated soil containing oil or grease. Only petroleum distillates should be used for cleaning electrical components. Petroleum solvents of the safety type with a flash point greater than 100° F (38° C) are recommended.

CAUTION: A SOLVENT THAT DOES NOT ATTACK EPOXY OR POLYESTER BASED MATERIALS SHOULD BE USED.

Apply the solvent with a soft brush or rag. Be careful not to damage the magnet wire or insulation on the windings.
Dry components thoroughly with moisture-free, low pressure compressed air.

Cloth and Compressed Air

Cleaning with a dry cloth may be satisfactory when components are small, the surfaces are accessible and only dry dirt is removed. Blowing dirt out with compressed air is usually effective particularly when the dirt has collected in places that cannot be reached with a cloth. Use clean dry air at 30 PSI (206 KPA).

Brushing and Vacuum Cleaning

Dry dust and dirt may be removed by brushing with bristle brushes followed by vacuum cleaning. Do not use wire brushes. Vacuum cleaning is an effective and desirable method of removing dry and loose dirt.

Shell Blasting

Air blasting with ground nut shells may be satisfactory for removal of hard dirt deposits from insulation. Use mild abrasives such as 12-20 mesh ground walnut shells.

Steam Cleaning

If the generator is completely disassembled, including bearings and electronic components, steam cleaning of the major parts and windings is very effective. However, the machine must be thoroughly dried in an oven to remove all moisture before the generator can be put back into service.

DISASSEMBLY

REMOVAL FROM PRIME MOVER

BE SURE ALL POWER IS OFF BEFORE SERVICING. FAILURE TO FOLLOW ALL SAFETY INSTRUCTIONS CAN RESULT IN SERIOUS INJURY OR DEATH.

NOTE: Before disconnecting any electrical wiring, be sure it is marked and can be identified for reinstallation. Re-label as required.

1. Remove conduit box covers (Figure 6-1 and 6-2)

Figure 6-1

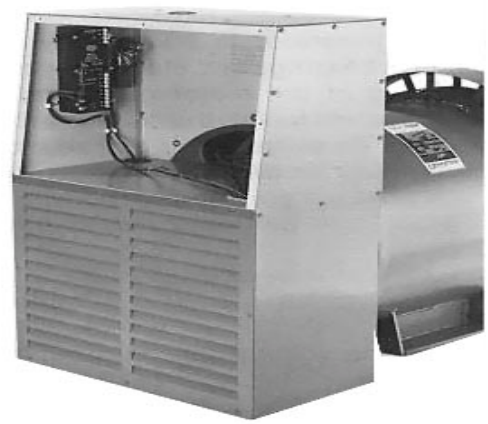

Figure 6-2

2. Disconnect all external wiring from the generator leads inside the conduit box.

3. Remove all conduits or ducting from the conduit box.

4. Attach a suitable hoist to the generator lifting

5. For single bearing generators, remove the bolts mounting the screen assembly to the SAE adapter and remove the screen. (Figure 6-3.)

Figure 6-3

(NOTE: Do not remove the drip cover from the screen assembly if so equipped)Remove the cap screws attaching the drive discs to the flywheel and remove the cap screws attaching the SAE adapter to the flywheel housing.

For two-bearing generators, disconnect the coupling or sheave and belts between the generator and prime mover. (Follow the coupling manufacturer's instructions for direct connection.)

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR

CONDUIT BOX REMOVAL

1. Note the location and markings (re-mark as required) and remove connections from voltage regulator (Figure 6-4), capacitor (Figure 6-5), and any other conduit box mounted controls.

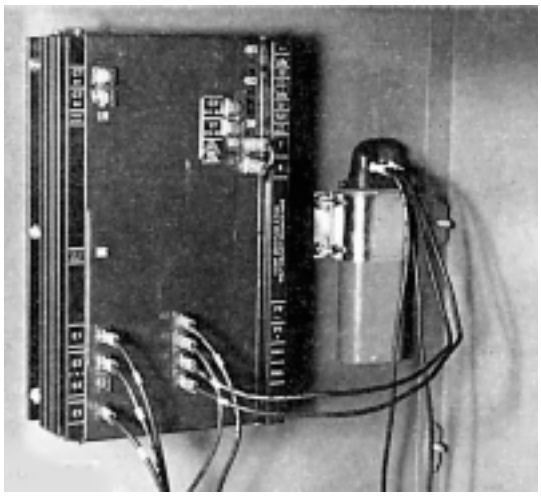

Figure 6-4

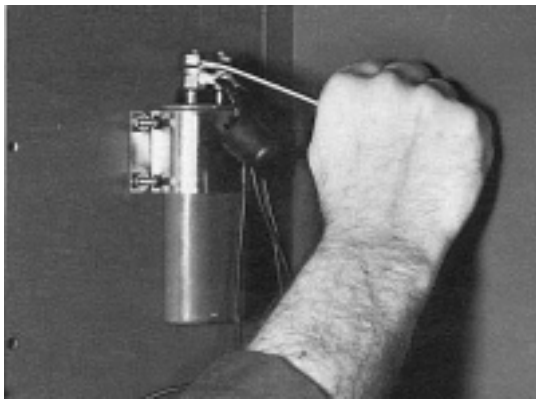

Figure 6-5

2. On generators equipped with bus bars, mark all connections and disassemble main stator (power) leads from the generator side of the bus bars.

3. Remove bolts holding conduit box in place. (Figure 6-6.)

Figure 6-6

4. Remove conduit box. (Figure 6-7).

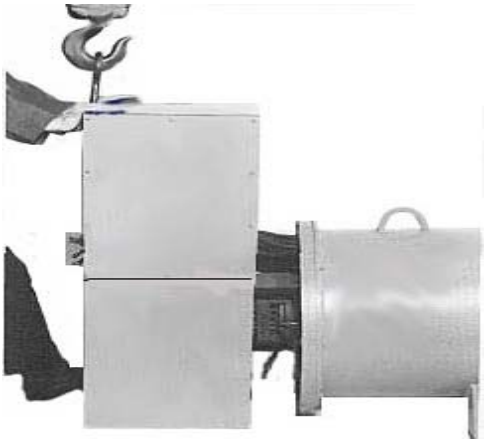

Figure 6-7

EXCITER STATOR (FIELD) REMOVAL

1. Disconnect Fl and F2 leads from the corresponding Fl and F2 terminals on the regulator.

2. Remove all cable ties so the Fl and F2 leads can be removed with the exciter stator. Remove the four cap screws and Belleville washers holding the exciter stator in place. (Figure 6-8.)

Figure 6-8

Remove the exciter stator. Using a lifting strap or fixture. (Figure 6-9.)

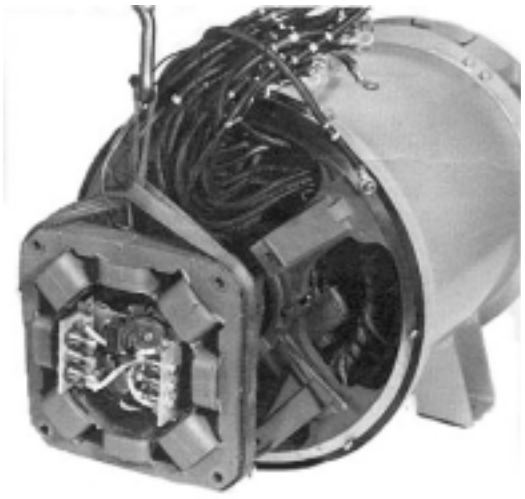

Figure 6-9

EXCITER ARMATURE (ROTOR) REMOVAL

1. Note markings and disconnect the main rotor leads coming out of the lead hole of the aluminum standoff plate from the rectifier aluminum angle. (Figure 6-10.)

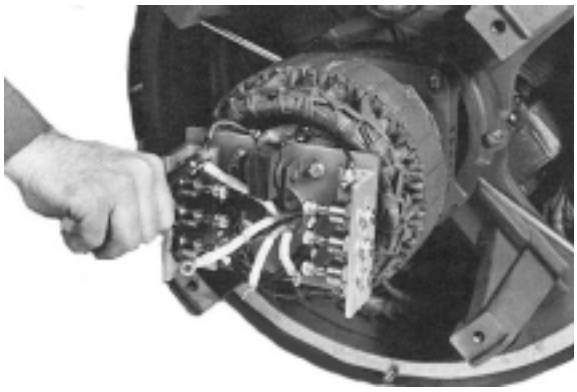

Figure 6-10

2. Remove the cap screw and Belleville washer that holds the exciter (rotor) armature to t generator shaft. (Figure 6-11.)

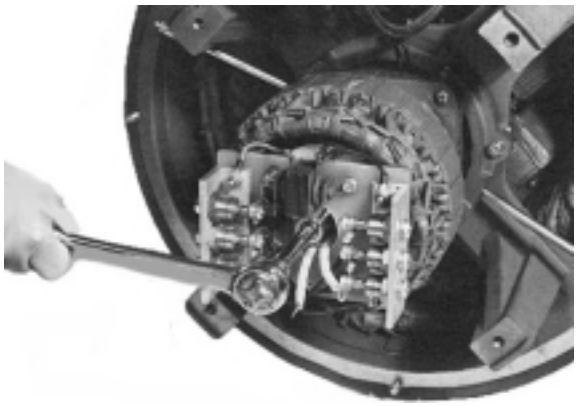

Figure 6-11

3.Use a six inch, 3/4-16NF, cap screw for a puller (See section 9.) The hole that the mounting bolt goes through is threaded. Screw the pull bolt into the hole and it will push against the end of the shaft. (Figure 6-12.)

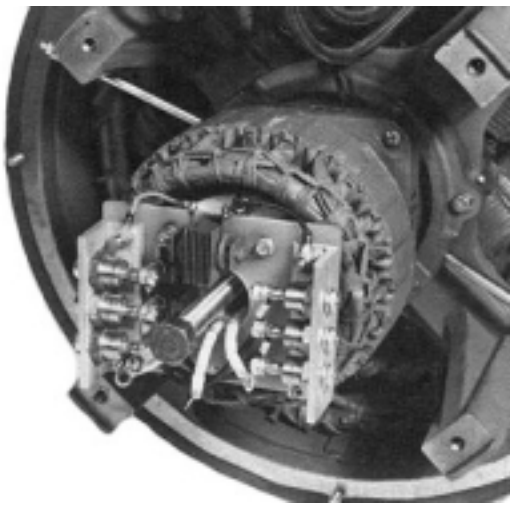

Figure 6-12

Carefully feed the main rotor leads through the hole as the exciter armature is removed. (Figure 6-13.)

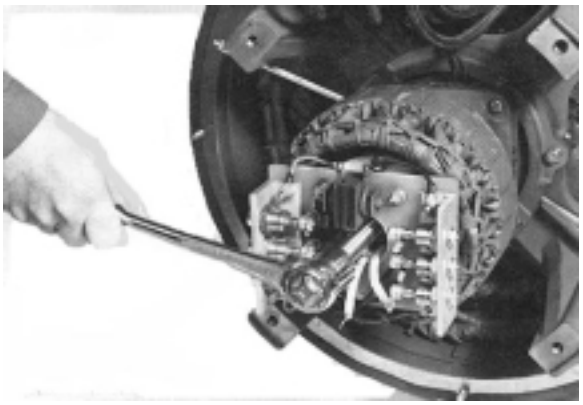

Figure 6-13

CAUTION:
DO NOT TIGHTEN THE PULLER BOLT BEYOND THE END OF THE THREADS. IF A BOLT WITH SUFFICIENT THREAD LENGTH CANNOT BE FOUND, USE A PIECE OF THREADED ROD WITH A NUT WELDED ON THE END.

PMG STATOR REMOVAL

1. Remove exciter armature. (Follow instructions found earlier in this section.)

2. Remove the PMG output leads from the capacitor (Figure 6-14) and loosen all cable ties so the leads can be removed with the PMG stator.

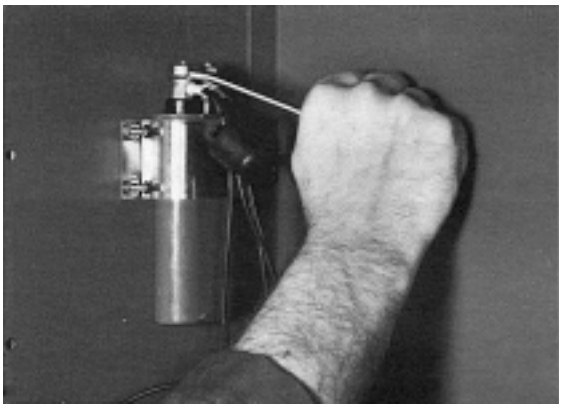

Figure 6-14

3. Note the position of the PMG stator leads that exit at the left inboard side or mark the stator so it can be reinstalled in the same position.

4. Remove the four mounting cap screws. (See Figure 6-15.)

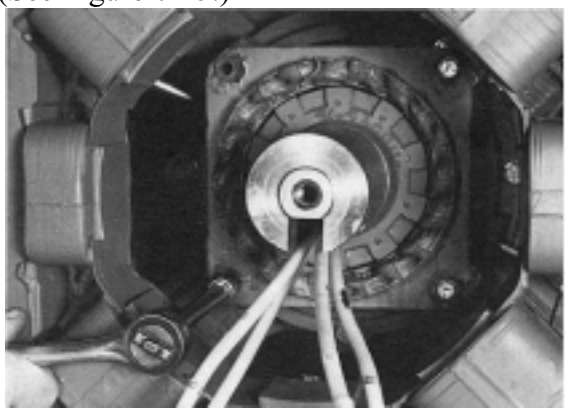

Figure 6-15

5. Carefully remove the PMG stator from its mounting pads and slide over the PMG rotor. The magnets used in the PMG are very strong and will resist removal of the PMG stator. (Figure 6-16.)

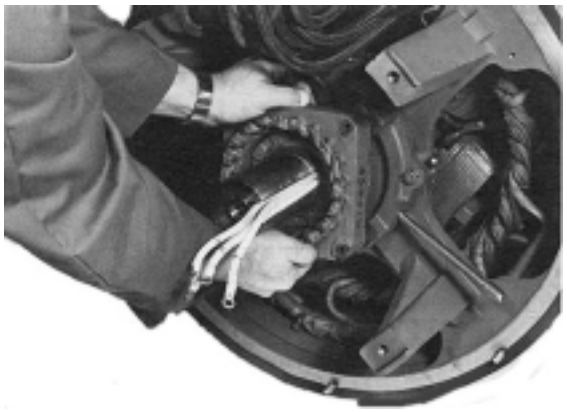

Figure 6-16

PMG ROTOR REMOVAL

1. Remove the exciter armature and PMG stator. (Follow instructions found earlier in this section.)

2. Remove the snap ring that holds the PMG rotor in place on the shaft. (Figure 6-17 and 6-18.)

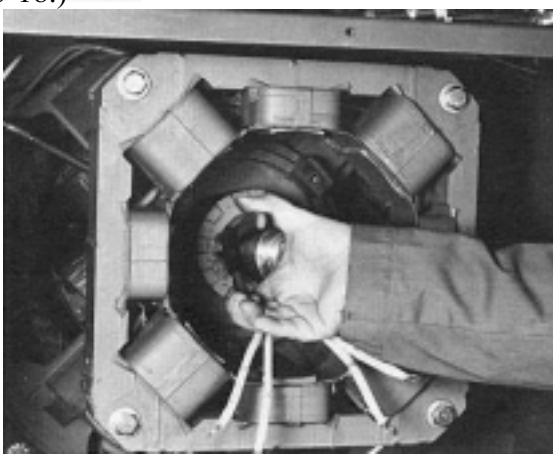

Figure 6-17

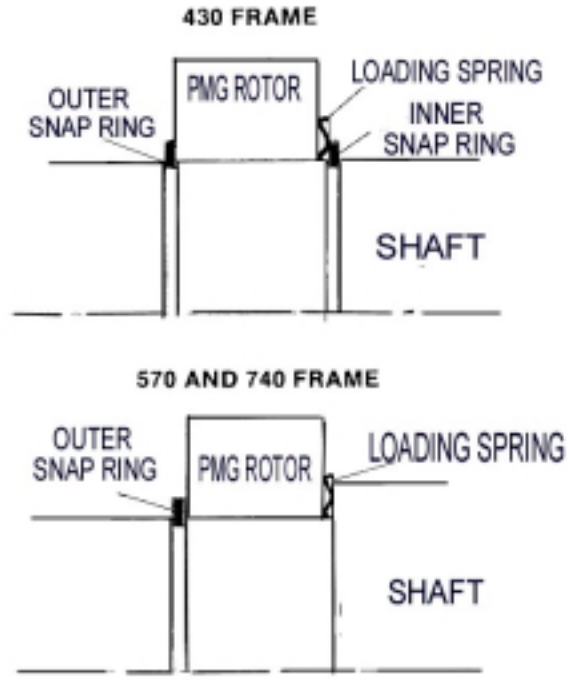

Figure 6-18

3. Slide the PMG rotor off of the shaft. (Figure 6-19.)

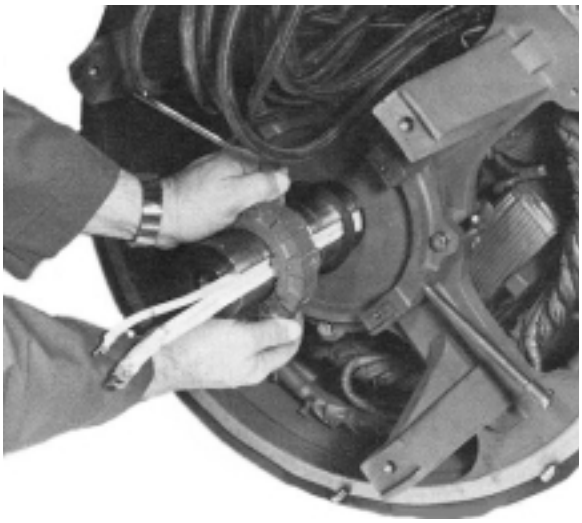

Figure 6-19

4. Remove the loading spring. (if the loading spring is not on the shaft, check to see if it is stuck on the back of the PMG rotor.).

5. On 430 frame generators a second snap ring is used inboard of the PMG rotor. (Larger generators have a step on the shaft.)

This snap ring must be removed before the generator main rotor can be removed. (Figure 6-20.)

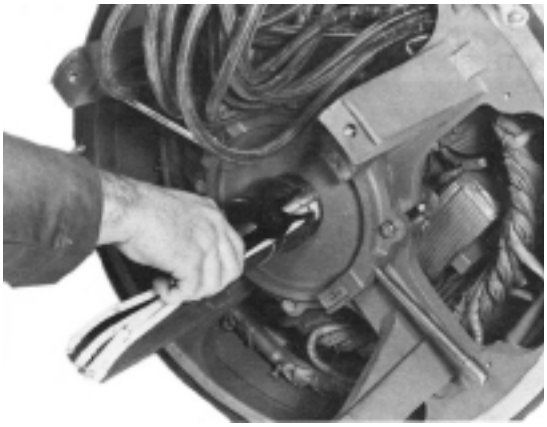

Figure 6-20

MAIN ROTOR REMOVAL

1. Remove the exciter armature and PMG.

2. For single bearing generators, remove the four cap screws holding the bearing caps to the front-end bracket. (Figure 6-21.) Remove the outer cap. (Figure 6-22.)

For two-bearing generators, remove the drive coupling or sheave and key from the shaft extension. Remove the four cap screws holding the bearing lock to the drive end bracket. (Figure 6-23.) Remove the four cap screws holding the bearing caps to the front-end bracket. (Figure 6-21.) Remove the outer cap. (Figure 6-22.)

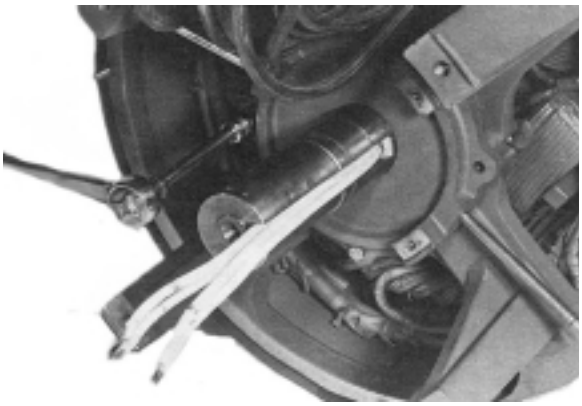

Figure 6-21

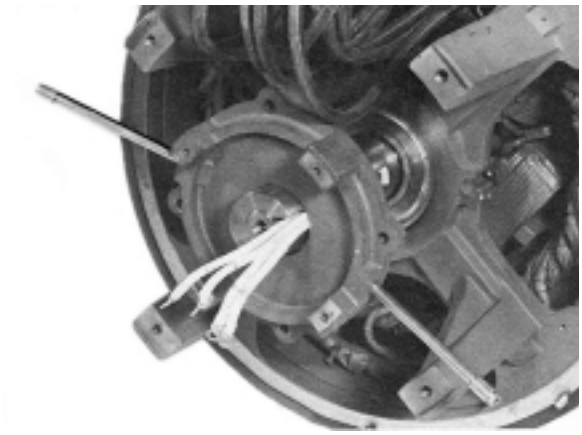

Figure 6-22

Figure 6-23

3. If the screen assembly is still mounted, remove bolts securing the screen assembly to the drive end bracket or the SAE adapter and remove the screen assembly. (Figure 6-24.) (NOTE: Do not remove the drip cover from the screen assembly if so equipped.)

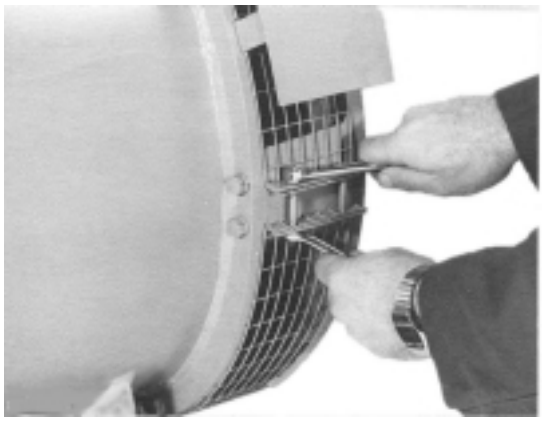

Figure 6-24

4. For single bearing generators, remove the cap screws and hardened washers holding the drive discs to the drive hub. (Figure 6-25.) Remove all drive discs (and spacers if any).

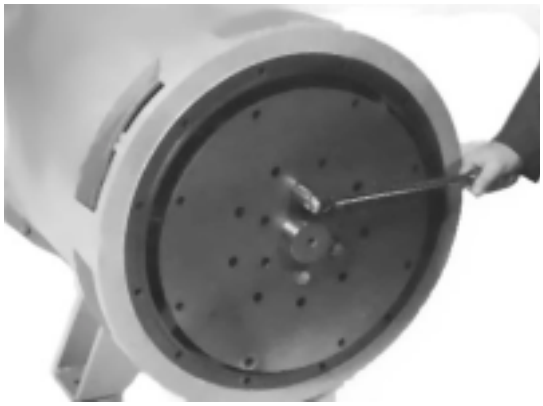

Figure 6-25

5. For single bearing generators, remove the cap screws holding the SAE adapter to the generator and remove the adapter. (Figure 6-26 and 6-27.)

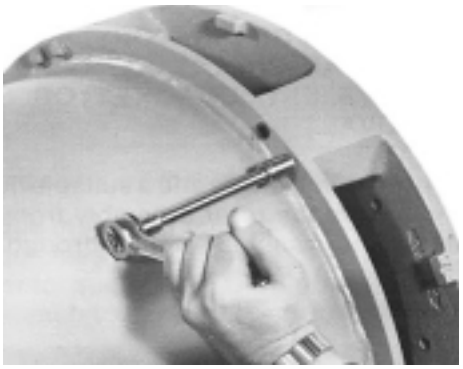

Figure 6-26

Figure 6-27

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN DRIVE END BRACKET OR SAE ADAPTOR REMOVAL

For two bearing generators remove the cap screws holding the drive end bracket to the generator and remove the bracket (Figures 6-26 and figure 6-28)

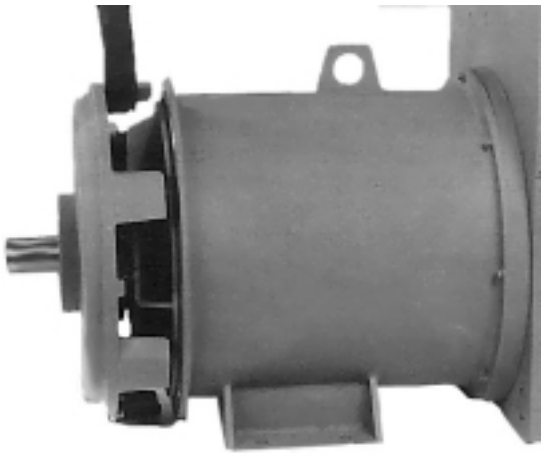

Figure 6-28

6. Using a rotor lifting fixture and a suitable hoist, carefully remove the rotor assembly from the main stator and frame assembly through the drive end. (Figure 6-29.)

CAUTION:
SPECIAL CARE SHOULD BE TAKEN WHEN REMOVING THE MAIN ROTOR, WINDING DAMAGE COULD RESULT IF THE ROTOR IS ALLOWED TO HIT THE MAIN STATOR.

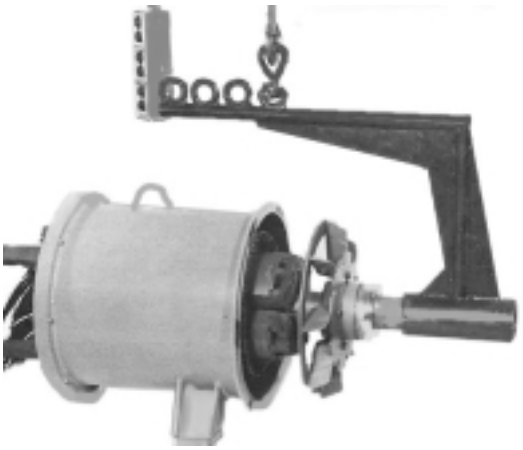

Figure 6-29

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

FRONT END BRACKET REMOVAL

1. Remove front bracket mounting screws. (Figure 6-30.)

2. Remove the front-end bracket from the main stator assembly. (Figure 6-31.)

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE FRONT END BRACKET REMOVAL

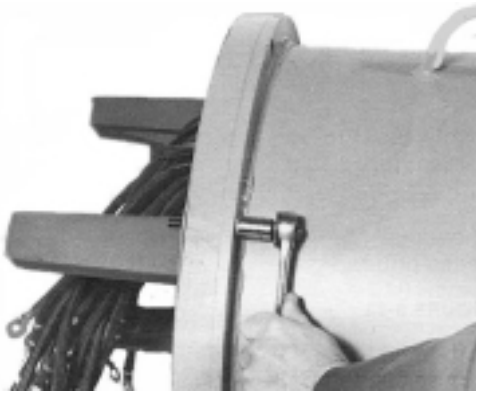

Figure 6-30

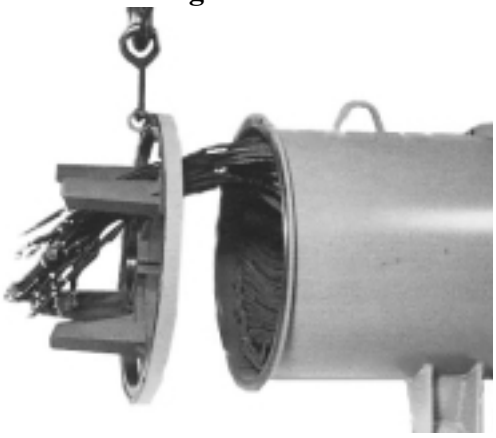

Figure 6-31

EXCITER INSPECTION

EXCITER STATOR

1. Clean dust and dirt from the exciter stator winding. (Figure 6-32.) (See section 5.)

Figure 6-32

2. Check the exciter stator for a loose, frayed, or burnt winding. Measure winding resistance and insulation resistance. (See section 8.)

Repair or replace as necessary. If field repair of the winding is necessary, contact Katolight for special winding procedures and materials.

3. Look for score marks in the bore of the exciter core caused by rubbing. (This could indicate bearing or assembly problems and should be investigated.)

EXCITER (ROTOR) ARMATURE

1. Clean dust and dirt from and rectifier assembly. (Figure 6-33) (See Section 5)

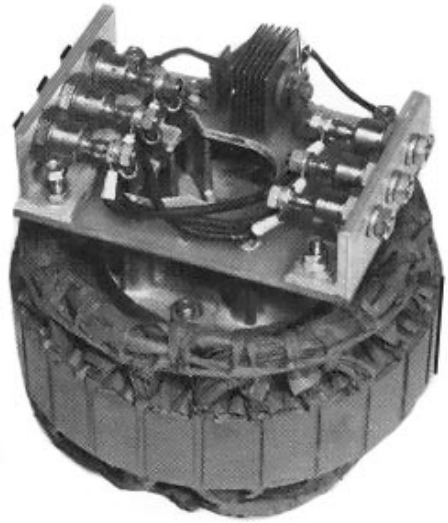

Figure 6-33

2. Check the exciter armature for burrs on the mating surfaces.

3. Check the rectifiers and surge protector for proper operation. Replace defective parts.

CAUTION: THREE FORWARD AND THREE REVERSE POLARITY DIODES ARE USED. BE SURE THE CORRECT PART IS INSTALLED IN THE CORRECT LOCATION. THE SURGE SUPRESSOR IS POLARIZED. OBSERVE POLARITY MARKINGS WHEN CHANGING THE SURGE SUPRESSOR

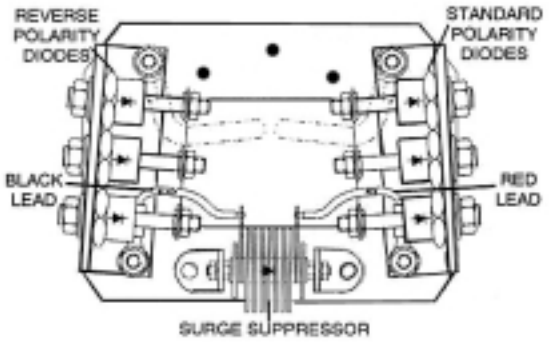

Figure 6-34

Torque mounting nuts to 80 in-lb. Torque lead terminal nuts to 25 in-lb. Never torque against the diode terminal - use a 7/16-in. wrench to support the terminal.

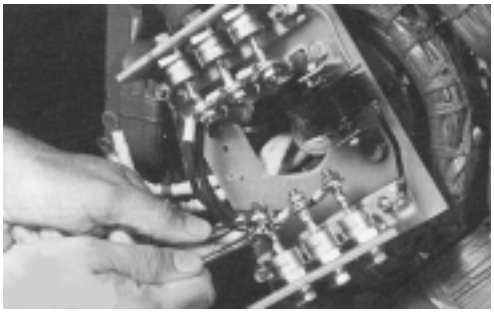

Figure 6-35

4. Check the exciter armature and rectifier assembly for loose, frayed, or burnt winding or loose connections. Measure winding resistance and insulation resistance. DO NOT megger diodes or surge suppressor. Repair or replace as necessary. If field repair of the winding is necessary, contact Katolight for special winding procedures and materials.

5. Look for score marks on the outside diameter of the armature core caused by rubbing. (This could indicate bearing or assembly problems and should be investigated.)

PMG INSPECTION

PMG STATOR

1. Clean dust and dirt from the PMG stator winding.

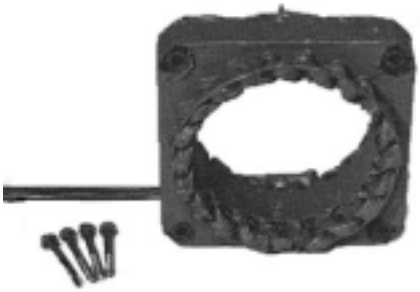

Figure 6-36

2. Check PMG stator for a loose, frayed, or burnt winding. Measure winding resistance and insulation resistance. (See section 8.) Repair or replace as necessary. Contact Katolight for special winding procedures and materials.

3. Look for score marks in the bore caused by rubbing.

PMG ROTOR

WARNING
THE PMG ROTOR USES VERY STRONG MAGNETS. KEEP AWAY FROM IRON AND STEEL PARTS THAT COULD BE DRAWN TO THE MAGNETS AS WELL AS OTHER COMPONENTS THAT CAN BE DAMAGED BY MAGNETIC FIELDS.

Figure 6-37

1. Clean dust and dirt from the PMG rotor.

2.Check to be sure all magnets are tightly bonded to the PMG rotor.

3.Check the bore and keyway of the PMG rotor for burrs or corrosion.

4.Look for score marks on the outside diameter caused by rubbing. (This could indicate bearing or assembly problems and should be investigated.)

5. Inspect snap rings and loading spring, replace as required.

MAIN ROTOR INSPECTION

BEARING

1. Check the bearing for damage or wear. Clean old grease from the bearing cap, and fill bearing cap grease cavity 1/3 to 1/2 full of r Chevron SRI (or equivalent).

CAUTION: If the bearing needs to be removed any reason, always install a new bearing.

2. If the bearing is to be replaced, remove with suitable puller. (Figure 6-38.)

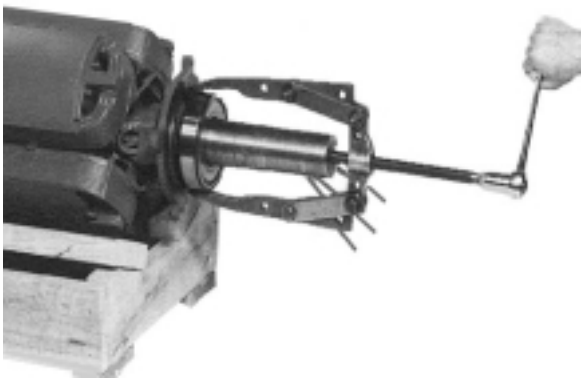

Figure 6-38

3.Be sure the inner bearing cap is on the shaft before installing the new bearing.

4. Heat the new bearing in an oven to a maximum temperature of 212°F (100°C). Apply a thin coat of clean lubricating oil to the press-fit area of rotor shaft. Install the bearing over the end of the shaft until it seats against the shaft shoulder as shown in Figure 6-39. The bearing should slide on the shaft and seated without excessive force. If the bearing binds on the shaft before being fully seated a piece of tubing, slightly larger than the press area, can be used to drive the bearing into place. Using light taps with a soft mallet, apply pressure to the inner race only.

CAUTION:
UNDER NO CIRCUMSTANCES SHOULD PRESSURE BE APPLI ED TO THE OUTER RACE OF THE BEARING, AS PERMANENT BEARING DAMAGE COULD RESULT.

Figure 6-39

Allow the bearing to cool for one hour before attempting to assemble the generator.

FAN

1. Check the fan for cracks or broken blades. Replace the fan if defective.

2. Mark the hub and fan for alignment, this is necessary to be sure the balance weights will be in the same position when the fan is reinstalled.

3. For single bearing generators. Remove the fan mounting cap screws (Figure 6-40) and slide the fan off the shaft. (Figure 6-41.) For two-bearing generators, remove the drive end bearing and bearing cap. (See bearing removal instructions.) Remove the fan mounting cap screws and slide fan off the shaft. (Figure 6-40 and 6-41.)

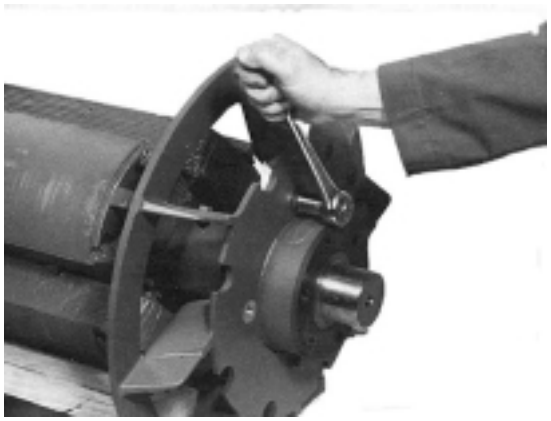

Figure 6-40

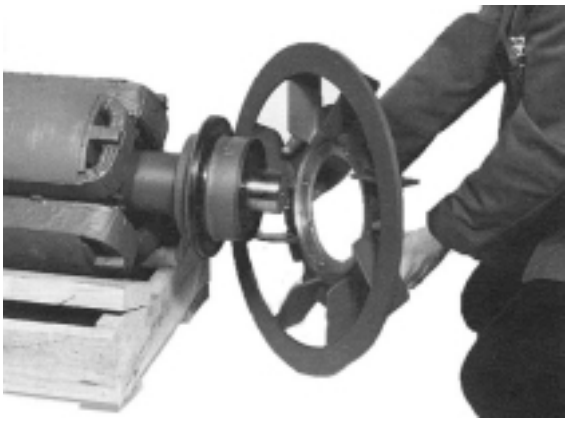

Figure 6-41

4. To reinstall, slide the fan on the shaft making sure the fan-mounting surface is toward the drive hub. Align reference marks (this is important for assembly balance) and mount the fan to the drive hub with the cap screws and Belleville washers. (Figure 6-42.) Torque the cap screws to 60 ft-lb. (81 N-m).

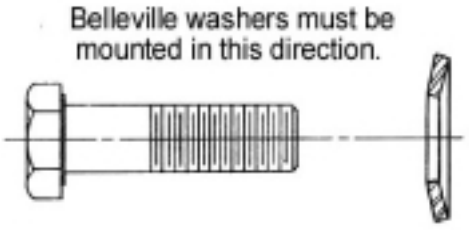

Figure 6-42

5. NOTE: Balance weights on the fan are for balance of the complete rotor assembly. The rotor assembly should be rebalance if a new fan has been installed.

6. On two-bearing generators, install bearing cap and new bearing according to the bearing assembly instructions. (Item A.)

Drive Hub (Single Bearing Generators)

1. Check the drive hub for cracks or stripped drive disc mounting holes. Replace the hub if defective.

2. If the hub is to be replaced, remove the fan (See Item B) and install a suitable puller to the hub. Remove the two set screws in the hub over the key. Using a torch, rapidly heat the hub at the outer diameter while tightening the puller. (This must be done rapidly before the heat can expand the shaft.) Remove the hub. (Figure 6-43)

Figure 6-43

3. To insure proper fan location, mark the new hub in the same place as the old hub relative to the keyway. Install key in shaft. Heat the new hub in an oven to 500°-600°F (260°-316°C). Use suitable heat resistant gloves, slide the hub over the key in the shaft until it seats against the shaft shoulder. (Figure 6-44.)

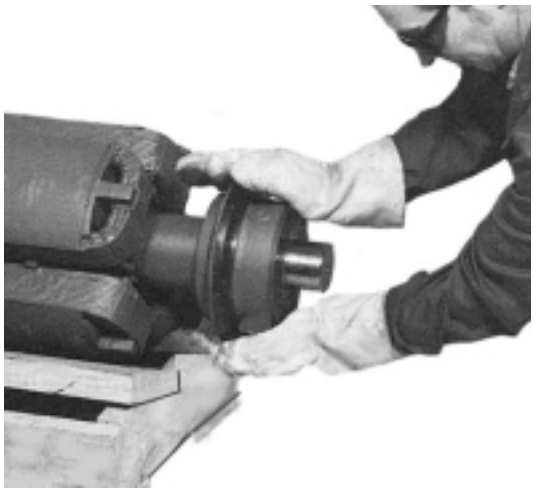

Figure 6-44

4. Allow the hub to cool for one hour. After the hub has cooled, tighten the set screws in the hub to 50 ft-lbs. (68 N.M.) torque. Match the alignment marks on the fan and hub and mount the fan. (See item B.)

5. Rebalancing the rotor assembly is not necessary if only the hub is replaced and the fan is mounted in the same location relative to the hub and shaft.

MAIN ROTOR CORE AND WINDINGS

1. Clean all parts. Remove dust and dirt from the rotor winding air passages with low-pressure, moisture-free air.

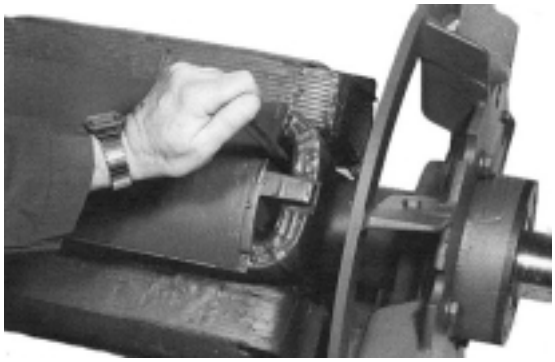

Figure 6-45

2. Check the rotor for loose, frayed, or burned windings. Measure winding resistance an insulation resistance. Test for shorted turns using an A-C impedance test A defective rotor winding must be rewound The rotor assembly must be rebalanced after any rework or repair has been completed.

DRIVE DISCS (SINGLE BEARING GENERATORS ONLY)

1. Inspect the drive discs for distorted or bent edges. (Figure 6-46) Inspect for worn mounting holes. Replace all defective discs as necessary.

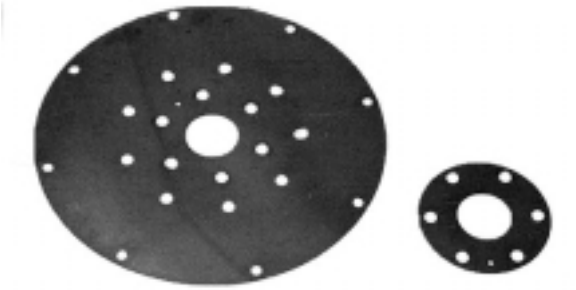

Figure 6-46

2. Inspect the drive disc mounting cap screws for damaged threads. Replace cap screws if damaged.

FRONT (EXCITER) END BRACKET INSPECTION

1. Remove the filler and drain grease pipes and the grease plugs from outer bearing cap. (Figure 6-47.)

Figure 6-47

2. Clean the end bracket, outer bearing cap, grease pipes, and cap screws to remove all dust, dirt, and grease.

3. Inspect the cap screws for stripped threads and replace if defective.

4. Inspect the end bracket for stripped threads, cracks, and burred or rough mating surfaces. Inspect the bearing bore for burrs or wear. If the bracket shows excessive bearing bore wear, it should be repaired or replaced. (Figure 6-48.)

Figure 6-48

5. Inspect the mounting pads for the PMG stator and exciter stator. Be sure they are smooth, clean, and free of any burrs or rust. That could interfere with proper alignment. (Figure 6-47 and 6-48.)

6. Re-assemble the grease pipes and fittings to the bearing cap.

DRIVE END BRACKET OR SAE ADAPTER INSPECTION

1. For two-bearing generators, remove the grease plugs from the bracket.

2. Clean the bracket or adapter, cap screws and screen assembly to remove all dust, dirt, and grease.

3. Inspect the cap screws for stripped threads and replace if defective.

4. Inspect the bracket or adapter for stripped threads, cracks, and burred or rough mating surfaces. (Figure 6-49 and 6-50.)

Figure 6-49

Figure 6-50

5. For two-bearing generators, inspect the bearing bore for burrs or wear. If the drive end bracket shows excessive bearing bore wear, it should be repaired or replaced.

MAIN STATOR INSPECTION

1. Clean dust and dirt from the stator frame and winding. (Figure 6-51.) (See section 5.)

Figure 6-51

2. Inspect the frame for stripped threads, cracks, burred mating surfaces, or other damage.

3. Inspect the stator for a loose, frayed, or burnt winding. Measure winding resistance and insulation resistance. (See section 8.) Repair or replace as necessary.

FRONT END BRACKET INSTALLATION

1.Install two guide pins (threaded rod can be used) into the generator side of the end bracket mounting holes. Align the guide pins with the holes in the generator frame and slide the bracket onto the frame. (Figure 6-52.) Install bracket mounting cap screws. (Figure 6-53.)

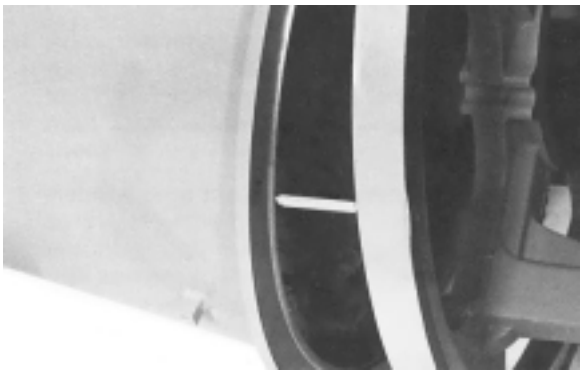

Figure 6-52

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE FRONT END BRACKET INSTALLATION.

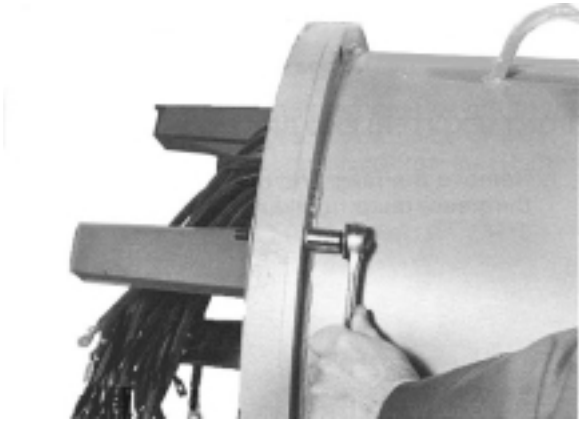

Figure 6-53

2. Remove the two guide pins and insert the remaining cap screws and torque to specifications given in section 12.

MAIN ROTOR INSTALLATION

1. Grease bearing cavity and bearing with Chevron SRI (or equivalent) grease.

2. Using a rotor lifting fixture and a suitable hoist, carefully install the rotor assembly into the main stator assembly through the drive end. (Figure 6-54.) Carefully feed the rotor leads through the front-end bracket shaft hole as the rotor is installed.

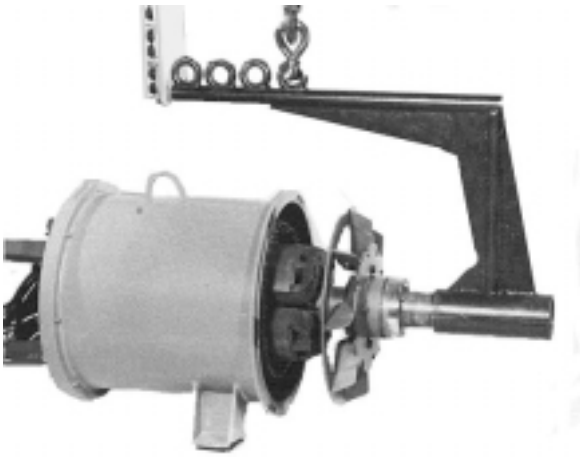

Figure 6-54

CAUTION:
SPECIAL CARE SHOULD BE TAKEN WHEN INSTALLINGTHE ROTOR ASSEMBLY. WINDING DAMAGE COULD RESULT IF THE ROTOR IS ALLOWED TO HIT THE MAIN STATOR.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

3. For single bearing generators, slide the SAE adapter over the fan and secure to the main stator and frame assembly with cap screws torqued per section 12. (Figure 6-55 and 6-56.) It may be necessary to raise the rotor assembly slightly to allow the mounting of the SAE adapter.

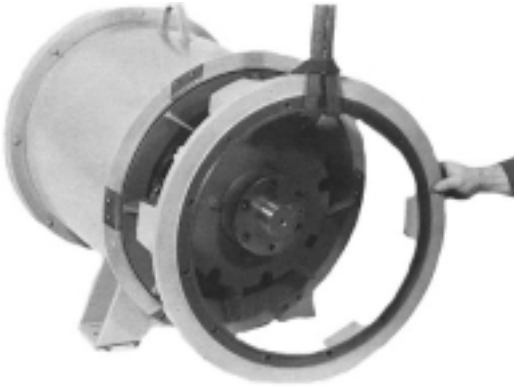

Figure 6-55

Figure 6-56

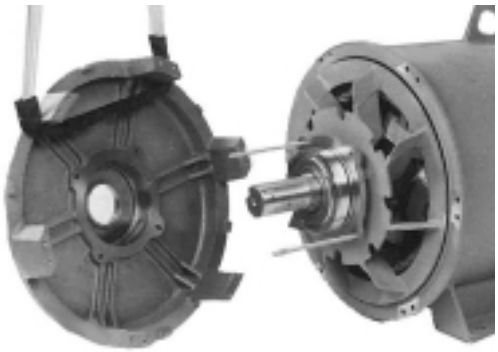

Figure 6-57

For two-bearing generators, insert two guide pins in the rear bearing lock holes. (Figure 6-57.) Fill the grease cavity of the drive end bracket 1/3 to 1/2 full of Chevron SRI (or equivalent) grease. Assemble all grease plugs in the bracket. Mount the bracket on the bearing and guide the bearing lock pins through the bracket holes. (Figure 6-58.)

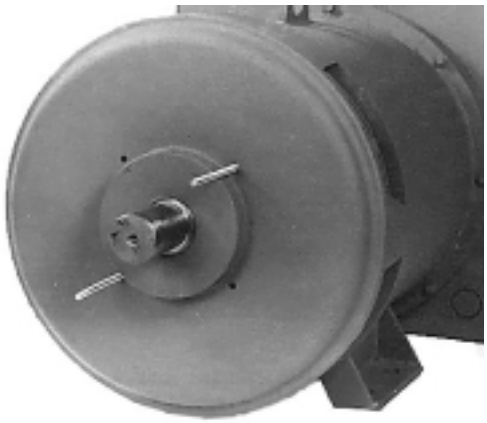

Figure 6-58

Align the drive end bracket and mount with the cap screws. (Figure 6-59.) Insert two cap screws with lock washers into the bearing lock and tighten. Remove the guide pins and replace with the remaining two cap screws with lock washers. Torque bearing cap screws to 25 lb.-ft (34 NM). Torque bracket mounting cap screws per specifications given in section 12.

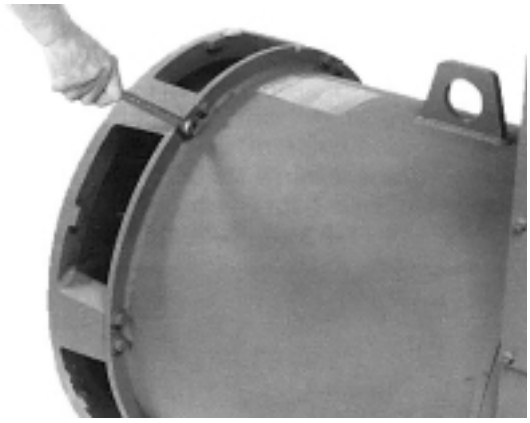

Figure 6-59

CAUTION:
ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TOASSIST IN THE DRIVE END BRACKET OR THE SAE ADAPTER ASSEMBLY.

4. For single bearing generators, insert a guide stud into the drive hub. Position all spacers (if any), then all drive discs, one at a time until all discs are installed. (Figure 6-61.)

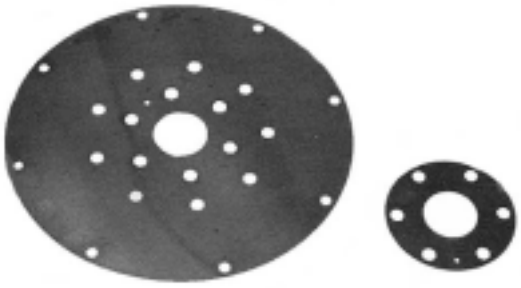

Figure 6-61

Make sure that all disc mounting holes at the inner and outer diameter are properly aligned. Secure the discs with the grade eight 5/8-18 cap screws and hardened washers. Torque to 192 ft-lb. (260 N-m). Torque the bolts in sequence according to Figure 6-62.

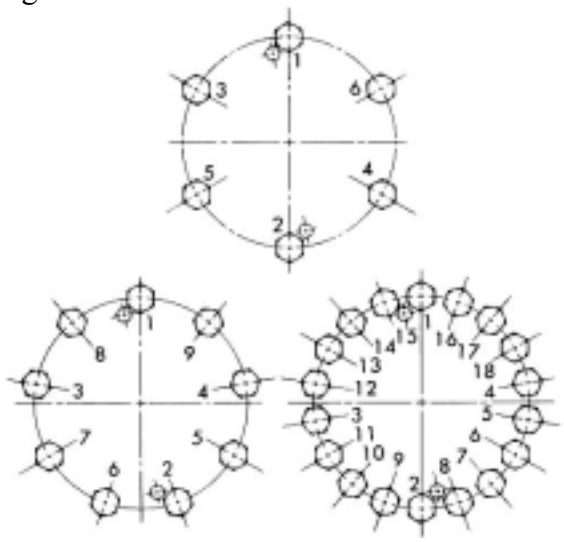

Figure 6-62

5. Install the outer bearing cap on the exciter end. (Figure 6-63.) Align holes in inner and outer bearing cap and install cap screws. Torque to 25 lb.-ft (34 N-M) (Figure 6-64.)

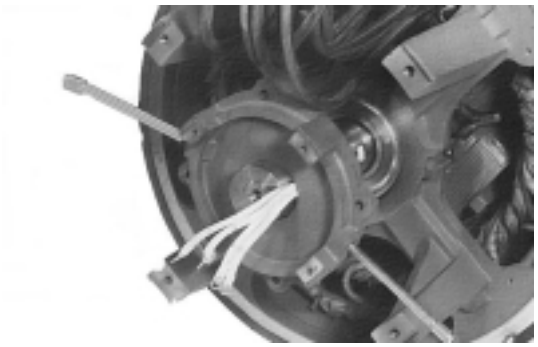

Figure 6-63

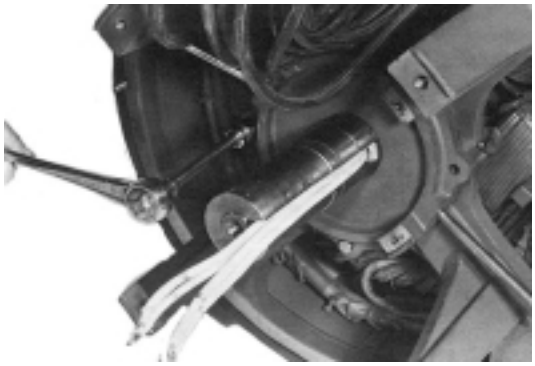

Figure 6-64

PMG INSTALLATION

1. Install inboard snap ring, where supplied, and loading spring on shaft. (Figure 6-65.)

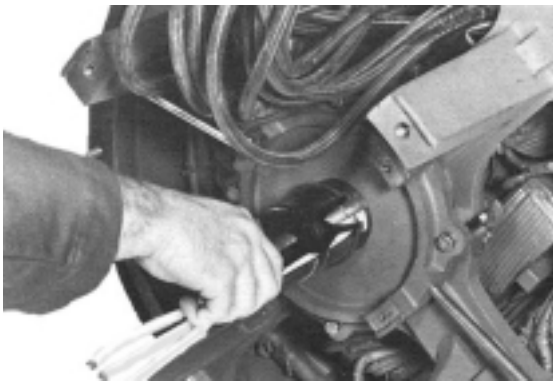

Figure 6-65

2. Slide PMG rotor onto shaft. (Figure 6-66.)

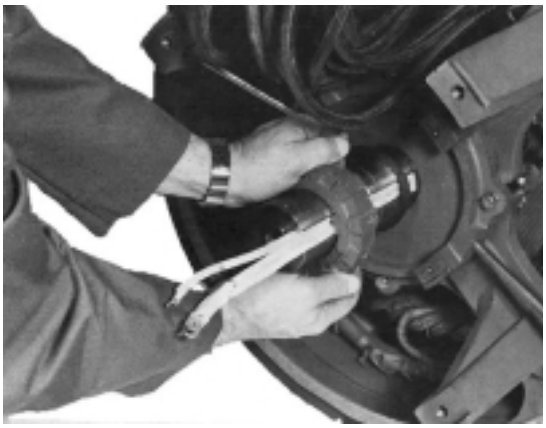

Figure 6-66

3. Install snap ring. (Figure 6-67.) Use a piece of pipe slightly larger than the shaft (2-3/4 inches) to push the rotor back against the loading spring until the snap ring seats in the slot. (Figure 6-68.)

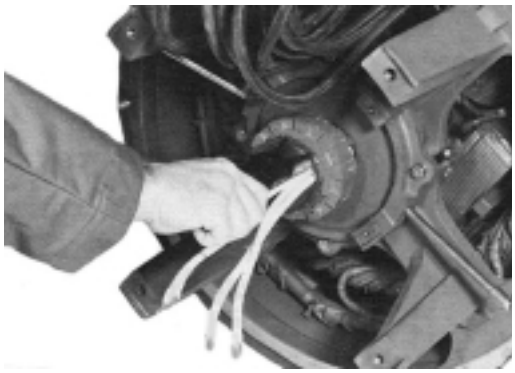

Figure 6-67

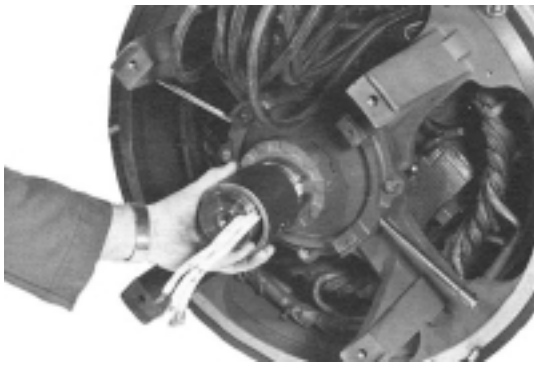

Figure 6-68

4. Install the PMG stator on its mounting pads, with the leads in the left (9:00 o'clock) inboard position, and secure with the four

mounting cap screws and Belleville washers. (Figure 6-69 and 6-72.)
Torque to 4 ft-lb. (5 N-M).

Figure 6-69

5. Route and secure PMG moving parts.

EXCITER INSTALLATION

1. Attach a wire to the main rotor leads and feed the wire through the armature bore and the lead hole in the aluminum standoff plate. On larger exciters, it will be helpful to install a guide pin in the end of the shaft to support the armature while fishing the rotor leads through. (Figure 6-70.)

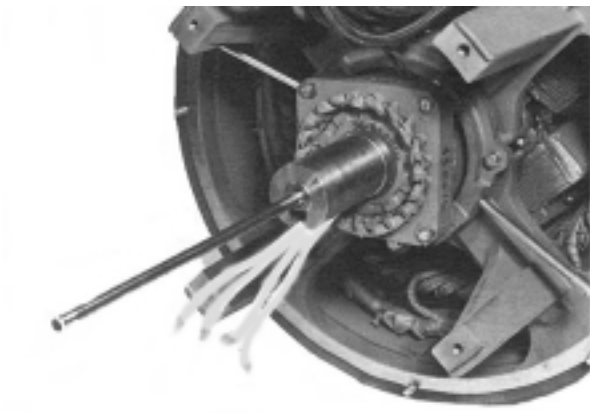

Figure 6-70

Align the key in the armature bore to the keyway in the shaft. Slide the armature on the shaft while feeding the main rotor leads through the lead hole in the aluminum standoff plate. (Figure 6-71.)

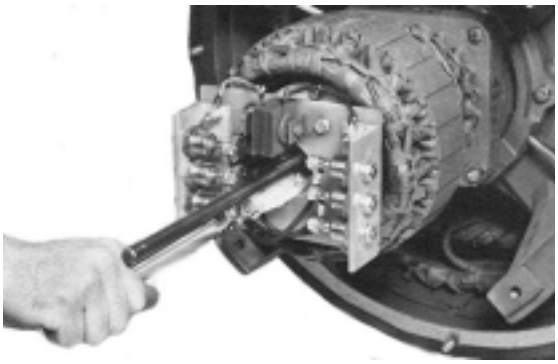

Figure 6-71

Insert the cap screw and Belleville washer (Figure 6-72.) through the mounting hole in the aluminum standoff plate and secure to the shaft (Figure 6-73). Tighten the cap screw until the armature seats on the shaft. Torque to 84 lb.-ft (114 N-M).

Figure 6-72

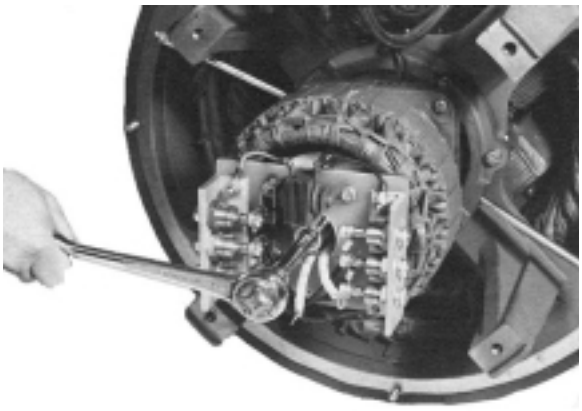

Figure 6-73

2. Observe the polarity markings and connect the main rotor leads to the rectifier

assembly. (Figure 6-74.) Torque the nuts to 4 ft-lb. (5.4 N-M).

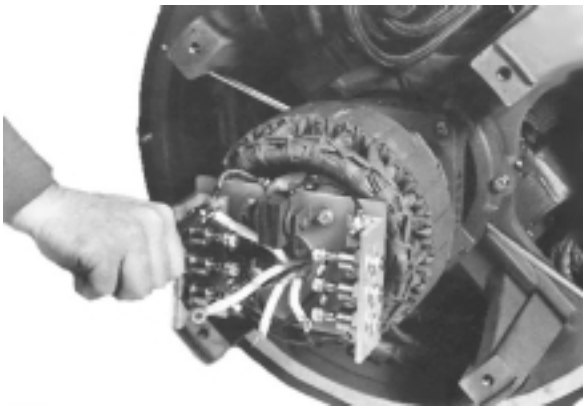

Figure 6-74

3. Position the exciter field leads at the left (9:o'clock) inboard position. Using a suitable lifting device, mount the exciter stator on the front e bracket mounting pads and align the mounting holes. (Figure 6-75.) Mount the cap screws with Belleville washers. (Figure 6-72.) Torque t cap screws to 60 ft-lb. (81 N-M). Route and secure the exciter stator leads away from any moving parts.

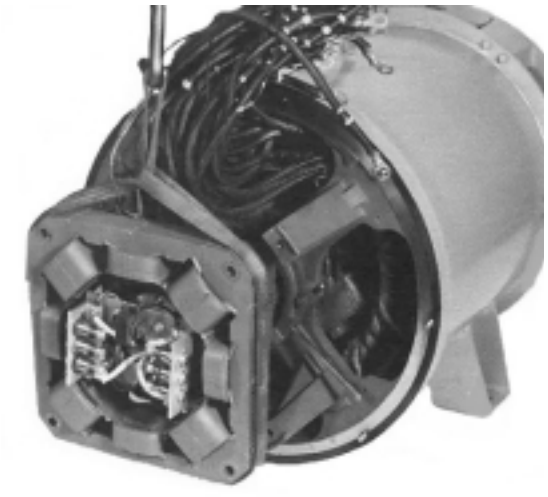

Figure 6-75

CONDUIT BOX INSTALLATION

1. Install the conduit box over the main stator leads (be sure the leads are in the upper compartment and secure with bolts and lock washers. (Fig 6-76 and 6-77.)

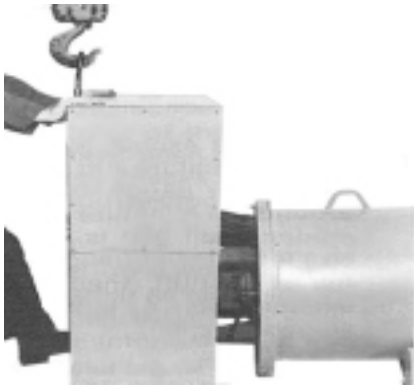

Figure 6-76

Figure 6-77

2. On generators with bus bar assemblies, reassemble main stator leads and insulating blocks to bus bars. (Figure 6-78.)

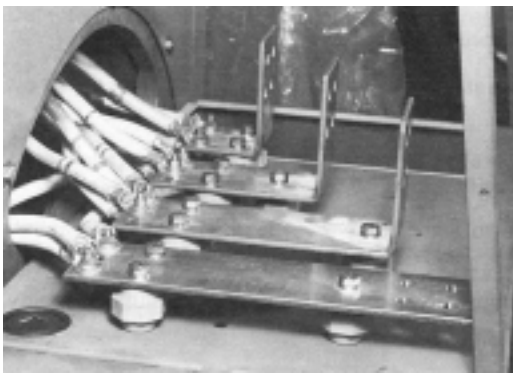

Figure 6-78

3. Reconnect exciter leads, PMG leads and other accessories according to the connection prints and markings installed before disassembly.

ASSEMBLY TO PRIME MOVER

1. Attach a suitable hoist to the generator lifting lugs, and move the generator until the generator foot mounting holes are aligned with the base and slightly above.

2. For single bearing generators, if the screen assembly is mounted on the adapter, remove the mounting bolts and remove the screen. (Figure 6-79.)

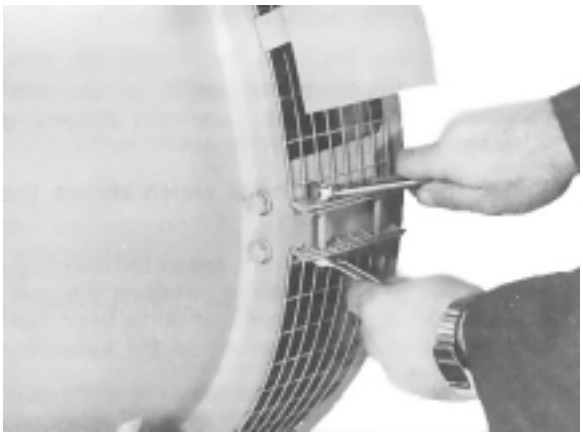

Figure 6-79

(NOTE: Do not remove the drip cover from the screen assembly if so equipped.) Insert two guide pins in the flywheel and two in the flywheel housing. Adjust the generator position until the drive discs are piloted in the flywheel. Remove the guide pins and secure the discs with Grade 8 place bolts and hardened washers or Grade 8 cap screws and heavy series lockwashers.

Torque per specifications given in section 12.

Position the generator so that the SAE adapter mates with the flywheel housing.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJUY OR EQUIPMENT DAMAGE.

CAUTION:
DO NOT FORCE THE ALIGNMENT OFTHE UNITS. SHIFT THE GENERATOR FROM SIDE TO SIDE OR RAISE OR LOWER WITH A LIFTING DEVICE AS NECESSARY.

It may be necessary to use shims under the mounting feet of either the generator or the prime mover to obtain proper alignment. Use the same shims as removed under disassembly or proceed as follows: Using the extreme bottom four cap screws, mount the SAE adapter to the flywheel housing.

With a .0015 to .002 inch feeler gauge at the extreme top of the adapter to flywheel housing fit, raise the generator or lower the prime mover until the gauge is snug. Relieve just enough to release the feeler gauge and torque the remaining SAE adapter cap screws to the flywheel housing.

Mount the screen assembly and tighten the mounting bolts.

For two-bearing generators, align the coupling halves or sheaves between the generator and the prime mover by adding shims under the feet.

3. Shim under the generator feet for proper support, ensuring that the generator mounting surfaces are level.

4. Install the mounting bolts that secure the generator to the base.

5. For two bearing generators, assemble the coupling halves or sheave belts between the generator and the prime mover. (Follow the coupling manufacturer's instructions for assembly and alignment.)

6. Connect all conduits and ducting to the conduit box.

7. Connect all external wiring to the generator inside the conduit box.

8. Check the exciter air gap (the gap between exciter armature and stator) by inserting a .010 inch feeler gauge in the gap and rotating around the armature diameter to ensure the minimum air gap is available. (See Figure 80.) If the feeler gauge cannot be rotated full revolution, then check for a "cocked" exciter stator or loose stator mounting screws.

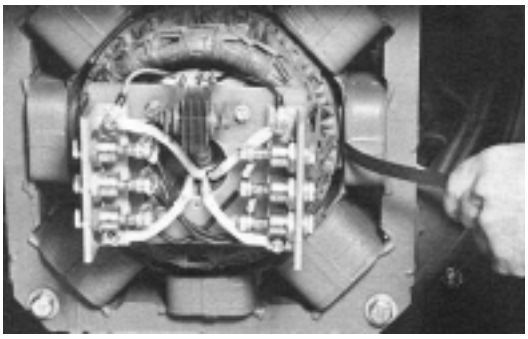

Figure 6-80

NOTE: On single bearing units, the exciter air gap cannot be checked properly until the generator is mounted to the prime mover.

9. Install the conduit box covers.

TROUBLESHOOTING

INTRODUCTION

This section is intended to suggest a systematic approach to locating and correcting generator or regulator malfunctions. The sections are arranged according to the symptoms of the problem. The steps in each section have been arranged in an attempt to do the easy checks first then to prevent further damage when troubleshooting a disabled machine.

The first and perhaps most important step of troubleshooting should be to gather as much information as possible from personnel who may have been present during the failure. Information on how long the generator had been running, what loads were on the line, weather conditions, what protective equipment operated, etc., can help isolate the problem.

Always make a thorough visual inspection to check for any obvious problems before attempting to run the generator.

WARNING
HIGH VOLTAGES CAN BE PRESENT AT THE GENERATOR AND REGULATOR TERMINALS. HIGH RESIDUAL VOLTAGES CAN BE PRESENT EVEN WITH THE REGULATORDISCONNECTED OR ITS FUSES REMOVED. SOME EQUIPMENT (SUCH AS SPACEHEATERS) MAY BE ENERGIZED WHEN THE GENERATOR IS OFF. TOOLS, EQUIPMENT, CLOTHING, AND YOUR BODY MUST BE KEPT CLEAR OF ROTATING PARTS AND ELECTRICAL CONNECTIONS.

SPECIAL CAUTION MUST BE TAKEN DURING TROUBLESHOOTING SINCE PROTECTIVE COVERS AND SAFETY DEVICES MAY BE DISABLED TO GAIN ACCESS AND MAKE TESTS.

BE CAREFUL. SERIOUS PERSONAL INJURY OR DEATH CAN RESULT FROM THESE HAZARDS. CONSULT QUALIFIED PERSONNEL WITH ANY QUESTIONS.

SYMPTOM:		
NO VOLTAGE OR RESIDUAL VOLTAGE	Regulator Fuse Blown Check fuse with ohmmeter.	Replace bad fuse.
	Voltmeter Off	Check to be sure meter phase selector switch is not in the off position.
	Defective Voltmeter	Verify proper operation of panel meter with another meter that is known to be accurate.
	Incorrect Connections	Verify generator connections.
	Defective Connections/Wiring	Inspect all wiring for grounds, open circuits & short circuits.
	No Regulator Input	Measure voltage at regulator input (PMG output)
	Defective Diodes, Surge Suppressor	Test generator with constant excitation (12 volt battery test) refer or Generator Windings
	Voltage Regulator Protective Shutdown Circuits are Operating	Correct problem and adjust regulator. Refer to regulator manual.
	Voltage Regulator Inoperative	Adjust or replace regulator. Refer to regulator manual.

LOW VOLTAGE - NO LOAD	Under speed Operation	Check speed using tachometers and/or frequency meters.
	Defective Voltmeter	Verify operation of panel meter with another meter that is known to be accurate.
	Residual Voltage	Disconnect Fl and F2 leads at the voltage regulator. If voltage goes down continue on to next step, if voltage does not change refer to troubleshooting for symptoms of "No Voltage - No Residual Voltage".
	Incorrect Generator Connections	Verify generator connections refer to drawings supplied V generator set and section 3.
	Defective Connections / Wiring	Inspect all wiring for grounds, open circuits, short circuits, and loose and dirty connections.
	Regulator Adjustments	Adjust regulator. Refer to regulator manual. Check exciter field volts.
	Defective Diodes, Surge Suppressor, Generator Windings	Test generator with constant excitation (12 volt battery test)
	Voltage Regulator not Operating	Adjust or replace regulator. Refer to regulator manual. Properly

LOW VOLTAGE WHEN LOAD IS APPLIED	Overload	Measure amps and verify that the load does not exceed nameplate rating of the generator
	Defective Ammeter	Verify operation of ammeter by using a separate meter known to be accurate
	Droop Circuit	If the generator set is equipped for paralleling, some voltage droop is normal as load increases. Refer to the regulator instruction manual
	Continue troubleshooting for symptoms “Generator Produces Low Voltage - No Load”.	Continue troubleshooting for symptoms “Generator Produces Low Voltage - No Load”.
HIGH VOLTAGE	Defective Voltmeter	Verify operation of panel meter with another meter that is known to be accurate
	Incorrect Operating Speed	Verify speed with tachometer or frequency meter.
	Incorrect Connections	Verify generator connections Refer to drawings supplied with generator set
	Defective Connections / Wiring	Inspect all wiring for grounds, open circuits, and short circuits.
	Regulator Adjustments	Adjust regulator. Refer to regulator manual
	Diode Polarity Incorrect	Check diodes, verify proper diodes are installed and polarity is correct.
	Voltage Regulator not Operating	Adjust or replace regulator. Refer to regulator instruction manual.

VOLTAGE IS FLUCTUATING	Incorrect Speed	Verify speed with tachometer or frequency meter.
	Unstable Speed	Verify governor stability.
	Voltage Regulator Stability	Adjust regulator stability. Refer to regulator manual.
	Defective / Loose Connections	Inspect all wiring for loose or dirty connections.
	Defective Diodes, Surge Suppressor or Generator Windings	Test generator with constant excitation (12-volt battery test).
	Remote Voltage Adjust	Check operation. Refer to regulator manual.
	Defective Regulator	Replace regulator. Refer to regulator manual.
OPERATES SATISFACTORILY WHEN COLD, BUT SHUTS DOWN WHEN WARM	Regulator Shutdown on Over Temperature	Correct cooling problems. Refer to regulator manual.
BUILDS VOLTAGE FROM STARTUP,THEN GOES TO LOW (RESIDUAL) VOLTAGE	Regulator Protective Circuit is Operating	Check indicators on regulator. Correct problems and adjust as required. Refer to regulator manual.
EQUIPMENT RUNS NORMALLY ON UTILITY POWER, BUT WILL NOT RUN ON GENERATOR SET	Voltage Waveform is Distorted	Analyze load. Excessive SCR (Thyristor) loading will cause distortion. Some equipment may be sensitive to distorted waveforms. Refer to Katolight.

GENERATOR TESTING

VISUAL INSPECTION

Whenever testing and troubleshooting a generator set, it is always a good practice to make a thorough visual inspection. Remove covers and look for any obvious problems. Burnt windings, broken connectors, leads, mounting brackets, etc., can usually be identified. Look for any loose or frayed insulation, loose or dirty connections, broken wires. Be sure all wiring is clear of rotating parts.

Verify that the generator is connected for the voltage required this is especially important on new installations.

Check for any foreign objects, loose nuts, bolts, and electrical connectors. Clear paper, leaves, building materials, etc., that could be sucked into the generator. (Generators are air-cooled. Air enters the lower portion of the conduit box.) Check the air gap for clearance or obstructions (main generator and exciter).

If possible, rotate the generator rotor by hand to be sure it turns freely.

If serious problems can be identified before attempting to operate the machine, additional damage can be avoided.

CONSTANT EXCITATION (12V BATTERY) TEST

THEORY: The generator output voltage is dependent on generator speed, generator design, load, and exciter input current. If the generator speed and exciter input are known, the output voltage at no load can be measured and compared to the design value. Problems can be isolated to either the generator or regulator system by using this test.

TEST PROCEDURE:

1. Shut the generator set down.

2. Connect a voltmeter to the generator output.

3. Disconnect the Fl and F2 leads at the regulator.

4. Connect a 12-volt battery capable of supplying 1 amp to the Fl and F2 leads. Fl is plus **(+),** F2 is minus (—).

CAUTION: Beware of arcing when connecting leads. Stay clear of battery vents. Escaping hydrogen gas can explode. If hazardous conditions exist - use a suitable switch to connect or disconnect the battery.

5. With no load on the generator, (main breakers open) run generator at rated speed.

6. Measure the generator output voltage.

7. Shut generator down.

8. Disconnect battery (see Caution - Step 3).

9. Compare voltage reading with value shown in section 12.

Conclusion: If voltage readings are normal, the main generator and exciter are operating properly. Troubleshooting should continue with the regulator. If readings are not normal the problem is in the generator. Continue testing diodes, surge suppressor, windings.

MEASURING VOLTAGES

When testing the generator and regulator, the most frequent (and usually easiest) measurement will be a voltage. The generator will need to be running at rated speed and may have some of the protective guards and covers removed. BE CAREFUL. Keep yourself and your test leads out of the way. It is best to shut the unit down when connecting meters. When using alligator clips or push on terminals, be sure the leads re supported so vibration does not shake them loose when running the generator set.

See figure 8-1 for measurement points and expected meter range settings.
When in doubt, start with a higher range and work down.
Consult meter instruction manual to verify its operation and limitations.

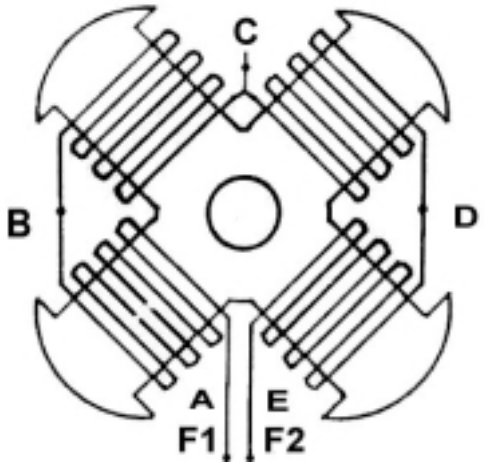

Figure 8-1

TYPICAL VOLTAGE MEASUREMENTS

Voltage Measurement	Test Point	Meter/Range Selection Requirement
Generator Output Voltage	Output "T" leads or bus bars, also main circuit breaker "line" side.	System voltage - volts AC See generator nameplate and connection diagram.
Regulator Output (Exciter Stator Input)	Fl and F2 terminals at the regulator.	200 volts D.C. range. Fl is plus (+), F2 if minus (—
Regulator Sensing	El, E2, E3 terminals at the Voltage the regulator.	Usually the same as the system voltage (generator output volts). However, in some cases, sensing taken from winding center taps or instrument potential transformers. Maximum 600 volts AC **Example:** Center tap of 480-volt system would give 240 volts El, E2, or E3. **Example:** A 4160-volt system must use a transformer to step voltage down below 600 volts. See the connection diagram supplied with generator set.
Regulator Input Volts (PMG Output Volts)	"PMG" leads at the regulator or capacitor.	200-240 VAC 300 Hz @ 1800 rpm 180-220 VAC 250 Hz @ 1500 rpm

CURRENT (AMP) MEASUREMENTS

Current measurement (AC) can be easily taken with a clamp on type meter.
NOTE: Most clamp type ammeters will not measure D.C.

When measuring generator output current, be sure the clamp is around all cables for each phase. If the physical size of the conductors or the capacity of the meters will not permit all cables to be measured at once, Each one can be measured individually. Add the individual readings together to get the total. Compare readings to the generator nameplate (nameplate ratings are always given per phase).

Amperage should never exceed the nameplate rating when running the intended load. (Amperage may go above nameplate momentarily when starting large motors.) When measuring exciter field amps (Fl and F2 leads) a D.C. meter is required. The maximum field current under full regulator forcing is 6.5 amps D.C.

MEASURING RESISTANCE

The generator windings can be measured and compared to the values shown in the service specifications.

Main Stator

The main stator winding resistance is very low. A meter capable of readings in the milliohm range would be required. However, a standard V.O.M. can be used to check for continuity, shorts, or grounds.

Example: With leads disconnected, a measurement from T1 to T4 should be very low (continuity most V.O.M's). Measured from T1 orT4 to any other lead should be infinite. Measure from the 'T' lead the generator frame to check for grounds (reading should be infinite).

Normal full load reading is approximately 3 amps.

The exciter stator resistance is measured by disconnecting the Fl and F2 leads at the regulator. Measure the resistance between the leads (this value is 22-24 ohms on standard generators). Measure from the leads to the frame to check for grounds.

Note markings and disconnect the main rotor leads (Fl leads and F2 leads) from the rectifier assembly. Measure the resistance of the main rotor winding. Compare reading to value shown in service specification section 12. Measure from the leads to the exciter-mounting bolt to check for grounds.

Exciter Rotor

Disconnect the exciter rotor leads at the diodes (leave leads disconnected if proceeding to check diodes). Measure resistance between phases. Compare value to service specification section 12. Measure from the leads to the exciter-mounting bolt to check for grounds.

TESTING DIODES (RECTIFIERS)

Diodes perform the function of an "electrical check valve". They conduct in one direction only and are used to "rectify" ac current into dc current. To test, measure the resistance first in one direction and then reverse the leads and test in the other direction. The reading should be high in the reverse direction and low in the forward direction. A shorted diode will read low in both directions. An open diode will read high in both directions.

NOTES:
1. Two different polarities of diodes are used. The only difference is in the way the device is mechanically placed in the case. When changing diode, be sure the correct polarity is used.
Refer to section 6 figure 6-34.

2. Some meters do not have enough voltage output from their internal batteries to turn the diode on (about 0.6 volts is required), and the voltage can change with different

range settings. Consult the instruction manual for your meter.
3. Polarities supplied by the meters internal battery may or may not correspond to the (+) (—) markings on the meter.

INSULATION RESISTANCE - *GENERAL*

Insulation resistance is a measurement of the integrity of the insulating materials that separate the electrical windings from the generators steel core. This resistance can degrade over time or due to contaminants (dust, dirt, oil, grease, and especially moisture). Most winding failures are due to a breakdown in the insulation system. In many cases, low insulation resistance is caused by moisture collected when the generator is shut down. The problem can be corrected simply by drying out the windings. Section 5.

Normally the resistance of the insulation system is on the order of millions of ohms. It is measured with a device called a “megger” which is a megohm meter (Meg is for million) and a power supply. The power supply voltage varies, but the most common is 500 volts. A megger voltage over 500 is not recommended except for measuring medium voltage (2400/4160) stators only.

CAUTION: First disconnect any electronic components, regulators, diodes, surge protectors, protective relays, etc., will be destroyed if subjected to the high megger voltages.

To measure insulation resistance, connect the red or positive megger lead to the leads for the winding to be tested, connect the back or negative megger lead to the generator frame. Be sure the leads of the part being tested are not touching any metal parts of the generator. (If the neutral is grounded, it must be disconnected.) Take megger reading (refer to the manual for the megger).

INSULATION RESISTANCE - MAIN STATOR

CAUTION: Be sure the regulator, and any other electronic components, metering, protective relays, etc., are disconnected before meggering. High megger voltages will destroy these parts. All stator leads must be isolated from ground and connected together (on most systems with grounded neutrals - the neutral can be isolated from ground and used as a test point). Connect the positive megger lead to the main stator leads. Connect the negative megger lead to the generator grounding stud. Take the megohm reading (refer to instructions for the megger).

GENERATOR TESTING

The minimum acceptable value can be calculated using the following formula.
Minimum Insulation Resistance = Gen. Voltage + 1 (Megohms) / 1000
Example:
For a 480 volt generator
480 + 1 = 1.48 Megohms
If the reading is below the recommended value, the winding must be dried out or repaired.

INSULATION RESISTANCE - MAIN ROTOR

Disconnect the main rotor leads from the diode bridge on the exciter rotor. Connect the leads together with the positive megger lead. Connect the negative megger lead to a good ground on the rotor assembly such as the exciter mounting bolt. Take the megohm

reading (refer to instructions for the megger).
The minimum acceptable value is 1.5 megohms.

If the reading is low, the winding must be dried out or repaired.

INSULATION RESISTANCE - EXCITER STATOR

Disconnect the exciter leads Fl and F2 from the regulator. Never subject the regulator to a megger. Connect Fl and F2 together with the positive megger lead. Connect the negative megger lead to the ground stud. Take the megohm reading (refer to instructions for the megger).

The minimum value is 1.5 megohms.

If the reading is low, the winding must be dried out or repaired.

INSULATION RESISTANCE - EXCITER ROTOR

Disconnect the exciter rotor windings (6 leads from the diodes). Connect all leads together with the positive megger lead. Connect he negative megger lead to a good ground on the rotor assembly such as the mounting bolt. Take the megohm reading (refer to the instructions for the megger).

The minimum acceptable value is 1.5 megohms.

If the reading is low, the winding must be dried out or repaired.

MAIN ROTOR FIELD AC IMPEDANCE TEST

THEORY: The main rotor resistance can be measured with a very accurate meter that is able to measure low (1 ohm) resistance but it is difficult to determine if there are turn to turn shorts in the field pole windings. One shorted turn would only change a resistance reading on the order of one half of one percent.

The ac impedance test measures the impedance (inductance and resistance) of the field pole coils. Shorted turns in the field pole windings change the coil inductance to a much greater degree than the resistance.

PROCEDURE:

Step 1: The rotor must be supported on a non-magnetic surface such as a wooden skid. Do not use a steel table that would create a magnetic “short circuit” between the poles.

Step 2: Apply 120 volts ac to disconnected main rotor leads Fl and F2.

Step 3: Measure and record voltages pole. Between points “A” and “C”, “C” and “D”, “D” and “E” across each “B”, “B” and (Figure 8-1).

Step 4: The voltage readings should balance within one volt.

RESULTS: If the ac voltages are not balanced (30v ± lv ac with 120v ac input) across each pole, the winding has shorted turns and should be rewound.

Refer to Katolight for further information.

STANDARD TOOLS

The MagnaMAX generator is assembled with American standard SAE hardware.

All fasteners should be properly torqued. (See section 12). Torque wrenches ranging from 25 in-lb. through 200 ft-lb. should be available.

Electrical test equipment should include a voltmeter or multimeter (VOM), clamp on ammeter, accurate frequency meter or tachometer, and a megohmmeter. See section Generator Testing for more information.

SPECIAL TOOLS

In addition to the standard tools mentioned above, the following special tools would facilitate removal and installation of large and/or special parts. These tools can be obtained from the Katolight parts department.

Exciter stator lifting fixture (Figure 10-1).

Figure 10-1

In cases where the exciter stator is to be serviced without removing the generator conduit box this fixture can be used with overhead rigging to remove and reinstall the exciter stator.

Exciter rotor puller bolt (Figure 10-2). The exciter rotor has a built in pulling system. With the use of this bolt, the rotor can be easily removed from the shaft without damage to the winding.

Figure 10-2

The PMG rotor is installed to the generator shaft with a snap ring.

The nominal shaft diameter is 2-3/4 inches and the ring must be spread approximately 3/4 inches for removal. To install the snap ring, use a piece of pipe with a 2-3/4 inch I.D. (Figure 10-4). Push the PMG rotor and snap ring onto the shaft until the ring snaps into the groove.

Figure 10-4

Rotor lifting fixture (Figure 10-5). The main generator rotor is heavy (approximately 1/2 the weight of the generator) and difficult to handle. The proper fixture should be used whenever removing or installing the main

rotor into the main stator. Without proper care and equipment, the windings can be easily damaged.

Figure 10-5

MISCELLANEOUS

A selection of wiring devices such as electric connectors, tape, cable ties, crimping and stripping tools, etc., should also be a part of the generator service tool kit. The standard regulator uses flat 1/4 inch female insulated terminals for AWG #14 wire.

PREPARATION FOR SHIPMENT OR EXTENDED STORAGE

SHIPPING INSTRUCTIONS

Shipping and handling will be much easier if the generator is fastened to a suitable shipping skid that will allow handling by a forklift. The skid should extend beyond the generator in all directions. If the original skid is available it should be used. Katolight will supply shipping skid drawings upon request.
Overseas shipping may require special export crating. Check with your freight carrier.

When installed, single bearing generator rotors are supported on the drive end by the drive discs bolted to the engine flywheel. When the engine is removed, the rotor must be supported by an appropriate fixture to prevent main rotor, main stator or exciter damage (Figure 11-1). Before shipping any single bearing generator, the main rotor must be supported by the adapter using an appropriate fixture.

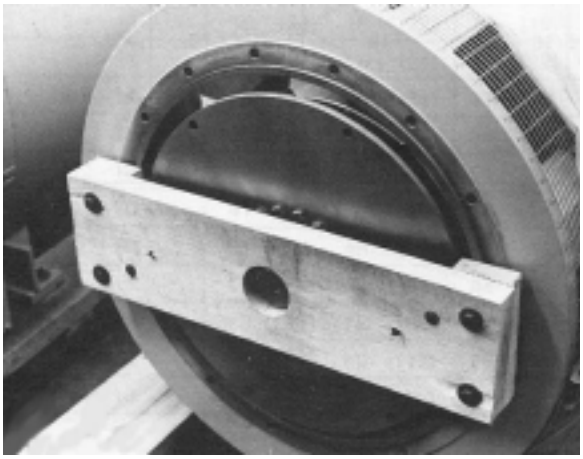

Figure 11-1

STORAGE INSTRUCTIONS

If the generator is placed in storage, the following precautions should be taken to protect it:

A. Equipment must be kept clean.

1. Store indoors.

2. Keep covered to eliminate airborne dust and dirt.

3. Cover openings for ventilation, conduit connections, etc. to prevent entry of rodents, snakes, birds, and insects, etc.

B. Equipment must be kept dry.

1. Store in a dry area indoor.

2. Temperature swings should be minimal to prevent condensation.

3. If stored in an unheated or damp building, space heaters will be required to prevent internal condensation.

4. Treat unpainted flanges, shafts, drive discs, and fittings with a rust inhibitor.

5. Check insulation resistance of all windings before starting the generator. If readings are low, the windings must be dried.

C. Keep bearings lubricated.

1. Every six months rotate shaft several turns to distribute grease in bearings.

2. If unit has been stored more than one year, add grease before start-up.

D. Review and follow instructions in Sections 3 and 4 before putting the gen-set into service.

CAUTION
DO NOT ATTEMPT TO TRANSPORT ANYGENERATOR WITHOUT PROPER ROTOR SUPPORT, EXTENSIVE EQUIPMENTDAMAGE CAN OCCUR.

TABLE 12-1: MAGNA MAX - FASTENER AND TORQUE SPECIFICATIONS

Part Description	Fastener Spec.	430-570 Frames		740 Frames	
		Size Dia.-Thread	Torque Ft-Lb.	Size Dia.-Thread	Torque Ft-Lb.

NOTES: For table 12-1
All fasteners are SAE (American) standard.
All torque values are for plated hardware that is standard on the MagnaMAX.
If hardware is replaced with non-plated, refer to Table 12-2.
Always use quality hardware of the grade specified.
Main Rotor Coil Supports 570 and 740 frame only. Not used on 430 frames.

TABLE 12-2: CAPSCREW TORQUE VALUES

NOTES: Cap screws threaded into aluminum may require reductions in torque of 3O% or more.

SAFETY

PLEASE REMEMBER SAFETY FIRST. If you are not sure of the instructions or procedures, seek qualified help before continuing.

This service manual emphasizes the safety precautions necessary during the installation, operation, and maintenance of your generator.

Each section has caution and warning messages. These messages are for your safety and the safety of the equipment involved. If any of the cautions or warnings is not readily understood, seek clarification from qualified personnel before proceeding.

Before any service work is done, disconnect all power sources and, where appropriate, lock out all controls, to prevent an unexpected start-up of the generator set. Proper grounding in compliance with local and national electrical codes must be provided. These safety precautions are necessary to prevent potential serious personal injury, or even death.

The hazards associated with lifting or moving the generator are pointed out in the installation and service sections; incorrect lifting or moving can result in personal injury or property damage.

Whenever the generator is running, always assume and proceed as if voltage is present. Residual voltage is present at the generator leads and at the regulator panel connections, even with the regulator fuse removed. Caution must be observed, or serious personal injury or death can result.

Whenever solvents, cleaners, or flammable liquids are present, adequate ventilation must be available to avoid fire, explosion, and health hazards. Always avoid breathing vapors and use suitable personal protective equipment to prevent personal injuries. (Such as eyes, face, and hand protection.)

This manual is not intended to be a substitute for properly trained personnel. Only qualified trained people should attempt repairs. The cautions and warnings point out known conditions that are potentially dangerous. Each installation will create its own set of circumstances. No manual can cover every possible situation.

When in doubt, ask. Don’t be embarrassed to ask, “dumb questions”. Remember that dumb questions are much easier to handle than dumb mistakes.

GENERAL INFORMATION

MECHANICAL DESIGN

General

All single and two bearing units are manufactured with cast iron end brackets and adapters, and fabricated steel frames. Flexible drive discs and SAE adapters are machined to SAE standards. Pre-lubricated, regreasable, shielded ball bearings are used on MagnaMAX^{DVR} generators. Standard units are fully guarded. Drip proof shields are available as an option.

Conduit Box

The large end mounted conduit box is constructed of formed sheet steel that will allow the addition of top mounted control packages. Refer to Katolight for top mounted controls of more than 240 lbs. There is ample room inside the conduit box for a circuit breaker (through 800A Frame) and other options. The conduit box cover properly directs outside ventilating air through the generator.

MagnaMAX^{DVR} Unirotor^{TM} Construction

An aluminum die cast rotor core affords high mechanical integrity and low vibration at operating speeds. Amortisseur winding and coil supports are die cast as an integral part of the rotor. Laminations are 4-pole, one piece laminations which are shrunk fit and keyed to the shaft. No dovetails, cross bolts or other pole to shaft connecting devices are used. The cast unidirectional aluminum alloy ventilation fan provides even air distribution to maximize cooling and generator efficiency.

Adapters and Drive Discs

All single bearing units are available with several adapters and drive disc arrangements. These can be shipped to order or can be changed in the field with standard shop tools. When changing flexible drive discs, spacers are used between the discs and the cast iron hub to maintain SAE standard dimensions.

ELECTRICAL DESIGN

All standard products have 2/3 pitch main windings to eliminate the third harmonic. This serves to lower operating temperatures, give lower harmonic content and better waveform, and extend the overall life of the generator.

Temperature Rise

All ratings and frame sizes are based on NEMA and CSA Class F and Class H temperature rises on both the rotor and stator windings. Ratings for British, German, French, IEC and all popular marine agencies are available.

Standby Generator Ratings

Synchronous generators used on emergency backup power can have temperature rises up to 25°C above those for continuous operation. (NEMA MG1 -22.40 and MG 1-22.84).

Premium Insulation System

All MagnaMAX^{DVR} generators are built with Class H or better insulation materials. All standard generators are suitable for continuous duty at Class F temperature rise and will give equivalent or better winding life expectancy to generators supplied with Class A or B insulation systems operated within their temperature limits. The varnishes and epoxies used are synthetic, non-hygroscopic. Multiple dip and bake cycles of the main winding, plus a final coat of epoxy, make the standard winding moisture and fungus resistant. The MagnaMAX^{DVR} rotor is wet wound with thermo-setting epoxy applied between each layer, plus a final coating of epoxy for moisture and abrasion resistance.

MagnaMAX^{DVR} generators can be ordered with an epoxy vacuum pressure impregnated insulation system as an option. (MagnaMAX^{DVR} generators with form wound coils include VPI as standard.)

Power Factor

All standard generators are designed for operation at rated kVA at 0.8 lagging power factor but can be operated at rated kVA over the 0.8 to 1 .0 power factor range.

MagnaMAX^{DVR} Voltage Regulator

The standard voltage regulator is a fully encapsulated, static types with a solid state build up circuit. Standard features include 3-phase RMS sensing, paralleling, adjustable under frequency protection, and over excitation protection. The regulator meets EMI suppression to Mil Std-461C, part 9. An optional feature is adjustable armature current limiting. See the regulator manual for more information.

HOW TO READ A MODEL NUMBER

It is extremely important to properly identify the machine when requesting parts or service. Always have the generator model number and serial number when requesting information from the factory. We cannot help you without this information.

An Example For MagnaMAX^{DVR} Generators ***431RSL 4009***

Character	Category	Description

INSTALLATION

RECEIVING YOUR MAGNAMAX^{DVR} GENERATOR

Upon receipt of the generator, it is recommended that it be carefully examined for possible damage incurred in shipment. The generator was given to the Freight Company in good condition, and they are responsible for the product from our dock to yours. Any damage should be noted on the freight bill before accepting the shipment. Claims for damages must be promptly filed with the Freight Company.

UNPACKING AND HANDLING

Read all instruction cards carefully. When lifting, attach an overhead crane to the lifting lugs on the generator frame. Apply lifting forces in a vertical direction.

WARNING
THE LIFTING LUGS ON THE GENERATOR ARE DESIGNED TO SUPPORT THE GENERATOR ONLY. DO NOT LIFT COMPLETE GENERATOR SET BY MEANS OF LIFTING DEVICES ON THE GENERATOR. PERSONAL INJURY OR QUIPMENT DAMAGE MAY OCCUR.

STORAGE

In the event that the generator is not to be installed on the prime mover immediately, it is recommended that it be stored in a clean, dry area that is not subject to rapid changes in temperature and humidity. See "STORAGE INSTRUCTIONS" for more information.

PREPARATION FOR USE

Although the generator is carefully inspected and tested in operation before it leaves the factory, it is recommended the unit be thoroughly inspected. The insulation on the wire should be inspected and all bolts should be checked for tightness.

Remove all shipping tapes, bags, blocks, and skids, which are used to prevent vibration and rotor movement during shipment. Dry, low-pressure compressed air of approximately 30 PSI (206 KPA) can be used to blow out the interior of the generator. In the case of two bearing machines, it is possible to turn the rotor by hand to make sure that it rotates smoothly without binding.

If the machine has been in storage for a year or longer it is recommended that it be lubricated according to the lubrication instructions and chart supplied in the maintenance section.
If the machine has been exposed to damp, humid conditions the insulation resistance should be checked. Refer to the instructions supplied in this manual.

GENERATOR MOUNTING - SINGLE BEARING

Single bearing generators are provided with an SAE flywheel adapter and flexible drive discs. Very close tolerances are maintained in the manufacture of the generator so that the alignment procedure is extremely simple. A coupling hub of nodular iron is shrunk on the shaft and special steel drive discs are bolted to the hub. Holes are provided in the periphery of the coupling disc, which correspond to tapped holes in the flywheel. The outside diameter of the discs fits in a rabbet in the flywheel so that concentricity is assured in all cases.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFITNG OR FOR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE

CAUTION: GRADE 8 CAPSCREWS OR GRADE 8 PLACE-BOLTS AND HARDENED WASHERS ARE REC-OMMENDED TO MOUNT THE DRIVE DISCS TO THE FLYWHEEL.DO NOT USE HELICAL OR OTHER LOCKING DEVICES UNLESS APPROVED.

The SAE adapter and the flywheel housing are designed to match each other with no further alignment necessary. Shims may be necessary under the feet of the generator to insure a solid mounting. See THE SERVICE SECTION for more information.

GENERATOR MOUNTING-TWO BEARING

Two bearing generators are provided with a shaft extension and key way. For direct-coupled sets the assembler furnishes a flexible coupling which is installed between the driver and the generator shaft.

IMPORTANT: Aligning the two machines as accurately as possible will reduce vibration, increase-bearing life, and insures minimum coupling wear. It may be necessary to shim the generator feet for proper support and alignment. Consult the coupling manufacturer's instructions for alignment specifications and procedures.

BELT DRIVE

Please refer to Katolight for applications involving belt driven installations.

ENVIRONMENTAL CONCERNS

Dirt, moisture, heat, and vibration are enemies of electrical equipment. The ambient temperature should not exceed the value shown on the generator nameplate. Generators for outdoor application should be protected from the elements by housings with proper openings for ventilation. This protection should be designed to prevent the direct contact of wind driven rain, snow, or dust with the generator. In moist or humid areas, such as the Tropics and marine serv-ice, additional protection is recommended. Although the standard windings are humidity and moisture resistant, special insulation and accessories such as space heaters can increase generator life. In extremely dirty and dusty environments a means of providing filtered cooling air to the generator is recommended. Please refer to Katolight for filter kits that are available.

ELECTRICAL CONNECTIONS

The generator conduit box construction allows conduit to enter the top, bottom, or either side of the box. A hole-saw or any suitable tool can be used to provide for the conduit entrance. Protect the interior of the generator from shavings when drilling or sawing. An approved connector must be used in conjunction with the conduit.

To minimize the transmission of vibration, it is essential that flexible conduit be used for all electrical cable entrance to the generator.

Refer to the connection diagram supplied with the generator and / or the proper diagrams shown in this section. Install all intercomponent and external wiring in accordance with the regulations of the national and local electrical codes. Clean all contact surfaces to assure good electrical bonding with the generator lugs or bus bars. Use heavy-duty terminal lugs or good quality clamps for making all connections. Insulate all connections in accordance with national and local regulations.

Be sure the generator frame is grounded to all the other components of the system with a ground wire in accordance with national and local regulations.

GENERATOR LEAD CONNECTIONS

The electrical connections in the conduit box should be made in accordance with the appropriate “connection diagram.” Use the diagram appropriate for the number of leads and voltage range required. Refer to the drawings supplied with the generator and to drawings in this section.

The final voltage setting is established within the selected range by an adjustment of the voltage regulator.

CAUTION: SOME GENERATORS HAVE MULTIPLE, IDENTICALLY MARKED, CABLES FOR EACH LEAD. CONNECT ALL IDENTICALLY MARKED CABLES TOGETHER WHEN MAKING CONNECTIONS.

PARALLELING OPERATIONS

MagnaMAX^{DVR} generators come standard with amortisseur windings die cast as an integral part of the rotor. This exclusive, Unirotor^{TM}, construction makes all MagnaMAX^{DVR} generators suitable for paralleling operations when the proper control equipment is added. Paralleling with other generator sets and / or with the utility power grid offers a number of advantages. Multiple unit installations increase power capacity; they can be added or removed from the line depending on the load requirements; they can be better maintained and repaired (since single source breakdown would mean total loss of power), and they often provide more reliable, efficient, and economical operation.

Successful parallel operation means that the generators deliver power to the external system without delivering power to each other, or accepting power from the load bus or power grid. Additional equipment is necessary to insure safe and successful operation.

PRIME MOVER

The prime mover provides the speed and torque which will be necessary to keep the machines in synchronized operation. A governor controls the prime mover's speed. The governor will directly control the watt or kW output and frequency of the unit. The governor must have special paralleling provisions to permit parallel operation with the other machines.

VOLTAGE REGULATOR

The voltage regulator controls the generator output voltage and the reactive power supplied by the generator. When two or more ac generators operate in parallel, the voltage regulator must have paralleling provisions (either internally or external to the regulator) to control the reactive or VAR load while it is in parallel operation. A separate paralleling current transformer is required to sense the reactive current and signal the voltage regulator. This additional paralleling circuitry is absolutely necessary to control the reactive current flowing between the generator sets.

SWITCHGEAR

There are additional relays and breaker controls that are necessary to insure safe, trouble free operation of paralleled units. Reverse power relays monitor the direction of power flow to insure that the generator is delivering power, not accepting it. These power relays control breakers, which are a means of connecting and disconnecting the generator from the load. The total system can include over-voltage, over-current protection, under frequency protection, power factor correction provision and a variety of associated control equipment from manual switchgear to microprocessors. The amount of control gear and level of sophistication will be determined by the needs and requirements of the particular application.

PARALLELING BASICS

The following points are basic criteria which must be met before two units can be paralleled. **THIS IS NOT MEANT TO BE SPECIFIC INSTRUCTIONS FOR PARALLELING OPERATION.**

1. Additional paralleling circuitry
   - A. Voltage regulator-paralleling provisions
   - B. Paralleling current transformer(s)
   - C. Paralleling provisions on governor controls
   - D. Switchgear

2. The voltage and frequency must be the same for all sets with voltages in phase.

3. The voltage regulation characteristics of the individual generators should be similar.

4. The generators must have the same phase rotation.

5.The driving engines should have the same speed regulation characteristics and the governors should be adjusted to give the same speed regulation.

Before operating generator sets in parallel, each set should be checked by starting, operating, and adjusting the sets as individual units before attempting paralleling.

REACTIVE LOAD CONTROL

When two identical generators are operating together in parallel and an unbalance occurs in field excitation, circulating currents begin to flow between the generators. This current will appear as a lagging power factor or inductive load to the highly excited generator, and as a leading power factor or capacitive load to the generator with the lower field current. This is known as the reactive circulating current and there are two methods of controlling it in parallel operation:

1. Reactive droop compensation. (Formerly known as parallel droop compensation.) The bus voltage droops, or decreases, as the reactive lagging power factor load is increased.

2. Reactive differential compensation. (Formerly known as cross current compensation.) The reactive differential compensation circuit allows parallel generators to share reactive loads with no decrease or droop in generator voltage.

The circuit must meet the following criteria:

A. All paralleling current transformers for all the generators being paralleled must be included in the secondary interconnection loop.

B. When different size generators are paralleled all paralleling current transformers must have the same proportional ratios that give approximately the same secondary current.

C. Voltage regulator paralleling circuitry must be the same.

D. Current transformer secondary and the generator lines must be isolated electrically.

E. It is also desirable to have an auxiliary contact on the main generator breaker to short the parallel CT secondary when that breaker is open (not connected to the load bus).

Because of the above criteria, reactive differential compensation cannot be used when paralleling with the utility power grid. There is no limit, however, in the number of generators that can be included in this type of circuit.

PARALLELING CIRCUITRY

Because of the number of variables involved in paralleling generator sets, every installation will have its own circuitry and methods or procedure of bringing paralleled units on line. There are numerous ways of connecting paralleled units and an almost unlimited variety of applications and associated equipment.

When parallel operation is desired, it is important that the control manufacturer, the generator manufacturer, and the systems engineer work together to insure the proper selection of all components. Please refer to Katolight for application assistance.

THYRISTOR OR SCR LOADING

Solid state electronic control devices which utilize thyristors or SCR firing circuits (such as variable frequency induction motor controls, precision motor speed controls, no-break powered battery chargers, etc.) can introduce high frequency harmonics which adversely affect or destroy the normal waveform of the generator. This creates additional heat in the generator stator and rotor, and can cause overheating. These devices can and do present problems to non-utility power generating equipment or any limited power bus system. The problems that can occur are not limited to the generator itself, but can effect the solid state control device, the equipment it controls, other associated loads, monitoring devices or a number of combinations over the entire system.

MagnaMAX^{DVR} generators can supply power to thyristor or SCR loads when properly applied. The standard voltage regulator is PMG powered and senses 3 phase RMS voltages for maximum stability against severely distorted waveforms. SCR type applications such as cranes, shovels, etc., require special consideration of the generator insulation system due to greater dielectric stress and severe environmental conditions. It is important that the control manufacturer, the generator manufacturer, and the systems engineer work together to insure the proper selection of all components. Please refer to Katolight for application assistance.

OPERATION

PRE-START INSPECTION

Before operating the generator for the first time, the following checks are recommended.

1. A visual inspection should be made to check for any loose parts, connections, or foreign materials

2. Check for clearance in the generator and exciter air gap. Be sure the generator set turns over freely. Bar the generator over by hand at least 2 revolutions to be sure there is no interference.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFITNG OR FOR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE

3. Check all wiring against the proper connection diagrams and make sure all connections are properly insulated. Support and tie leads to keep them from being damaged by rotating parts or by chafing on sharp corners.

4. Be sure the equipment is properly grounded.

5. Inspect for any remaining packing materials and remove any loose debris, building materials, rags, etc. that could be drawn into the generator.

6. Check fasteners for tightness.

7. Check to be sure no tools or other hardware have been left inside or near the machine.

8. Install and check to be sure all covers and guards are in place and secure.

WARNING
RESIDUAL VOLTAGE IS PRESENT AT THE GENERATOR LEADS AND AT THE REULATOR PANEL CONNECTIONS EVEN WITH THE REGULATOR FUSE REMOVED. CAUTION MUST BE OBSERVED OR SERIOUS PERSONAL INJURY OR DEATH CAN RESULT.

STARTING-UP THE GENERATOR

The following procedure should be followed for starting-up the generator for the first time:

1.The generator output must be disconnected from the load. Be certain that the main circuit breaker is open.

2.Disable the voltage regulator by removing the fuse.

WARNING
DO NOT OVERSPEED THE GENERATOR. EXCESSIVE CENTRIFUGAL FORCES COULD DAMAGE THE ROTATING FIELDS. BE PREPARED FOR AN EMERGENCY SHUTDOWN.

3.Follow the manufacturer's instructions and start the prime mover. Check the speed and adjust to the RPM shown on the generator nameplate.

4. Replace the regulator fuse and adjust the voltage to the required. Check all line to line and line to neutral voltages to be sure they are correct and balanced. If the voltages are not correct shut down immediately and recheck all connections.

5. Close the main circuit breaker and apply the load.

6. Monitor the generator output current to verify it is at or below nameplate amps.

7. Adjust engine speed at full load to 1800 rpm for 60 hertz, 1500 rpm for 50 hertz. (Refer to prime mover/governor instruction manuals.)

8. Before stopping the engine, remove the load by tripping the main circuit breaker.

FIELD FLASHING

The standard MagnaMAX^{DVR} generator is supplied with a PMG (permanent magnet generator). **It will never require field flashing.** In rare cases where a special generator may be furnished without a PMG, refer to the factory for more detailed information. Include the complete generator model and serial number.

VOLTAGE ADJUSTMENTS

The voltage regulator controls the generator output voltage. There is a cover to access the control panel on the side of the generator conduit box

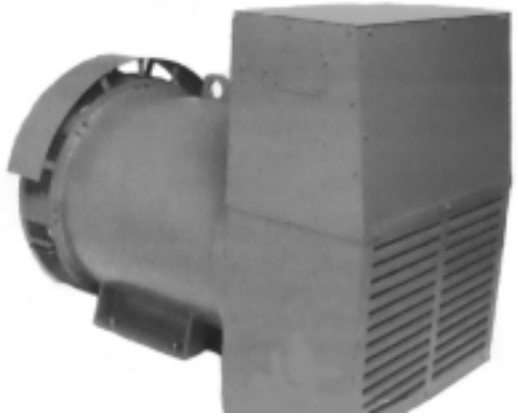

Figure 4-1

Figure 4-2 Regulator Access

Refer to the regulator manual for detailed information. In cases where special or remote mounted regulators are used, refer to instructions supplied by the generator set assembler and to the voltage regulator manual.

OTHER ADJUSTMENTS

Depending upon application, adjustments to other protective and control gear may be required. Refer to instructions provided by the by the supplier of the generator set.

The standard MagnaMAX^{DVR} voltage regulator also has many protective and control circuits.

It is imperative that the set up instructions for any regulator supplied be followed.

MAINTENANCE

GENERAL INFORMATION

Dirt, heat, moisture, and vibration are common enemies of a generator. Keeping the generator clean and dry, maintaining proper alignment of the generator and its prime mover, and preventing overloads will result in efficient operation and long life.

Generators that are outdoors should be protected from the elements by suitable houses or enclosures.

Dirt and dust will conduct electricity between points of different electrical potential. Moisture will aggravate the problem further. Insulation system failure can result if corrective action is not taken. Measuring insulation resistance can test the condition of the insulation system.
(See Generator Testing.).

Insulation resistance should be checked when putting the generator into service after it has been in storage and anytime contamination by moisture and dirt is suspected.

Normally, moisture buildup is not a problem while the generator is running, since heat produced internally will tend to keep it dry but can collect in the generator when it is shut down. The problem will be worse in humid environments or in areas where extreme temperature changes cause condensation (dew) to form inside the generator.

Space heaters, air filters, and premium insulation systems, such as our VPI process, should be considered in difficult environments.

Accumulations of dust and dirt not only contribute to insulation breakdown, but they can also increase temperature by restricting the dissipation of heat. Materials such as talc, lint, rock dust, or cement dust may obstruct the ventilation.

The most harmful types of foreign materials include carbon black, metallic dust and similar substances that not only impede ventilation, but also form a conductive film over the insulation, increasing the possibility of insulation failure.

Machines operating in dirty places should be disassembled and cleaned periodically.

AIR INTAKE AND EXHAUST

Check the area around the air intake and exhaust openings to be sure they are unobstructed.

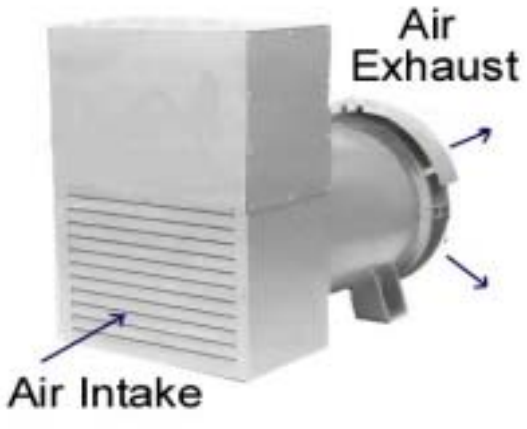

Figure 5-1

ELECTRICAL CONNECTIONS, WINDINGS

Inspect for loose or contaminated connections Check wires for cracked or frayed insulation. Tighten connections and replace defective or oil soaked insulation.

If inspection shows that varnish coatings on the windings have deteriorated, they should be coated with insulating varnish.

Please refer to Katolight for insulation system requirements.

LUBRICATION

All generators are lubricated before leaving the factory and are ready for operation. As a general rule, bearings should be re-lubricated annually or at the indicated intervals in table 5-3, whichever occur first.

Unusually severe operating conditions, such as high ambient or dusty environments, require more frequent lubrication (every six months or one half the table intervals, whichever occurs first).

Use Chevron SRI or equivalent anti-friction type high quality, grease with a lubrication temperature' range of -22° to +350° F (-30° to +175° C)

To add or renew grease, proceed as follows:

1. Stop unit.

2. Wipe the grease plugs and surrounding parts to insure they are clean.

3. Remove both the fill and drain plugs. See figure 5-2

4. Insert 1/8" N.P.T. grease fitting in fill pipe.

5. Free the drain holes of any hard grease, using a piece of wire it necessary.

6. Using a low-pressure grease gun, add grease according to the amounts in table 5-3.

7. Start unit with drain plug removed - fill pipe may be open or closed. Allow unit to run 15 minutes to allow excess grease to drain.

8. Stop unit, wipe off any drained grease, and replace filler and drain plugs.

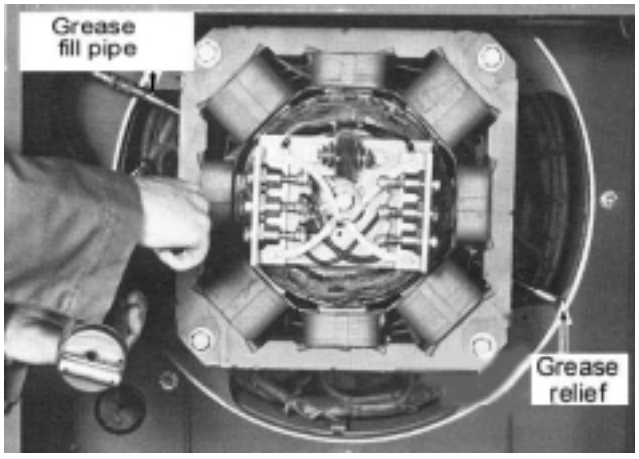

Figure 5-2

The amount of grease added is very important! Only enough grease should be added to replace the grease used by the bearing.

CAUTION: TOO MUCH GREASE CAN BE AS HARMFUL AS INSUFFICIENT GREASE. USE THE PROPER AMOUNT.

Type	Frame Size	Bearing Size	Amount of Grease			Intervals --- Max. hours or annually	
			Ounces	Cubic Inches	Teaspoons	60 Hz	50 Hz
Single Bearing Units	431,432, 433	314	1.2	2.1	7.0	6500	8400
	571,572, 573, 574	316	1.5	2.6	8.3	5600	7200
	741, 742, 743,744	322	2.4	4.2	14.0	3000	4500
Double Bearing Units	431,432	318	1.7	3.0	9.9	4600	6200
	571, 572, 573, 574	318	1.7	3.0	9.9	4600	6200
	741, 742, 743, 744	322	2.4	4.2	14.0	3000	4500

TABLE 5-3

During an overhaul, the grease reservoir should b thoroughly cleaned and new grease added. The reservoir should be 1/3 to 1/2 filled with new grease

DRYING ELECTRICAL INSULATION

Electrical components must be dried before placing in operation if tests indicate that the insulation resistance is below a safe value. (See Generator testing for test procedure.)

Machines that have been idle for sometime in unheated and damp locations, may have absorbed moisture. Sudden changes in temperature can cause condensation or the generator may have become wet by accident. Windings should be dried out thoroughly before being put into service. The following are recommended drying methods.

Space Heaters

Electric space heaters can be installed inside of the generator. When energized (from a power source other than the generator) they will heat and dry the inside of the generator. If an alternate source of electricity is not available, enclose the generator with a covering and insert heating units to raise the temperature 15-18 degrees F (8-10 degrees C) above the temperature outside of the enclosure. Leave a hole at the top of the enclosure to permit the escape of moisture.

Oven

Place the machine in an oven and bake it at a temperature not to exceed 194 F (90°C). The voltage regulator and any electronic component accessories must be removed from the generator when using this method.

Forced Air

A portable forced air heater can be used by directing heat into the air intake (conduit box) and running the generator with no load and without excitation (this can be accomplished by removing the regulator fuse). Heat at point of entry should not exceed 150° F (66° C).

"Short Circuit" Method

Using this method can dry out the generator quickly and thoroughly.

WARNING:
BE SURE THAT ALL OF THE FOLLOWING STEPS ARE PERFORMED AND ALL PRECAUTIONS TAKEN AS PERSONAL INJURY OR SERIOUS DAMAGE TO THE GENERATOR COULD RESULT.

1. Disconnect exciter leads Fl and F2 from the regulator.

2. Connect a battery or other dc power source approximately 20-35 volts to the exciter lead Fl and F2. An adjustable voltage source desirable, however, a rheostat (rated approximately 2 amps) in series with the dc power source will work.

3. Short circuit the generator output lead wires to each other (L1 to L2 to L3). If using jumpers, be sure they are large enough to carry full load amps.

4. Start the generator and measure the current through the output leads with a clip-on ammeter.

5. Adjust the voltage source to produce approximately 80% of the rated ac nameplate current but in no case exceed nameplate amps. If a adjustable source is not available and current is excessive, use a lower dc source voltage or larger resistor in series with the source.

Running time will be determined by the amount of moisture present in the machine. Insulation resistance checks should be taken every one to four hours until a fairly constant value obtained. (See section -

Generator testing for instructions on measuring insulation resistance.)

6. After the generator is dry and the insulation resistance is brought up to specification remove the short circuit from the line lead disconnect the dc source and reconnect the F and F2 leads at the regulator. Be sure all connections are tight and correct before attempting to run the generator.

CLEANING METHODS

When electrical components get dirty, the insulation must be cleaned. There are a number of acceptable methods for cleaning the generator, each of which will necessitate disassembly of the unit. The kind of dirt, and when the unit must be returned to service will determine the method of cleaning. Drying after cleaning is necessary.

Whenever the generator is disassembled, the windings should be given a thorough inspection and the insulation cleaned, if necessary. The inspection should include the connection of the windings, insulation, and varnish coverage. Check the winding ties and coil supports. Look for any signs of coil movement or looseness and repair as required.

An electric motor repair shop in your area can normally assist with the proper cleaning of the generator windings. They may also be experienced in special problems (such as seacoast, marine, oilrig, mining, etc.) that may be peculiar to a certain area.

Solvents

A solvent is usually required to remove accumulated soil containing oil or grease. Only petroleum distillates should be used for cleaning electrical components. Petroleum solvents of the safety type with a flash point greater than 100° F (38° C) are recommended. **CAUTION: A SOLVENT THAT DOES NOT ATTACK EPOXY OR POLYESTER BASED MATERIALS SHOULD BE USED.**

Apply the solvent with a soft brush or rag. Be careful not to damage the magnet wire or insulation on the windings.
Dry components thoroughly with moisture-free, low pressure compressed air.

Cloth and Compressed Air

Cleaning with a dry cloth may be satisfactory when components are small, the surfaces are accessible and only dry dirt is removed. Blowing dirt out with compressed air is usually effective particularly when the dirt has collected in places that cannot be reached with a cloth. Use clean dry air at 30 PSI (206 KPA).

Brushing and Vacuum Cleaning

Dry dust and dirt may be removed by brushing with bristle brushes followed by vacuum cleaning. Do not use wire brushes. Vacuum cleaning is an effective and desirable method of removing dry and loose dirt.

Shell Blasting

Air blasting with ground nut shells may be satisfactory for removal of hard dirt deposits from insulation. Use mild abrasives such as 12-20 mesh ground walnut shells.

Steam Cleaning

If the generator is completely disassembled, including bearings and electronic components, steam cleaning of the major parts and windings is very effective. However, the machine must be thoroughly dried in an oven to remove all moisture before the generator can be put back into service.

DISASSEMBLY

REMOVAL FROM PRIME MOVER

BE SURE ALL POWER IS OFF BEFORE SERVICING. FAILURE TO FOLLOW ALL SAFETY INSTRUCTIONS CAN RESULT IN SERIOUS INJURY OR DEATH.

NOTE: Before disconnecting any electrical wiring, be sure it is marked and can be identified for reinstallation. Re-label as required.

1. Remove conduit box covers (Figure 6-1 and 6-2)

Figure 6-1

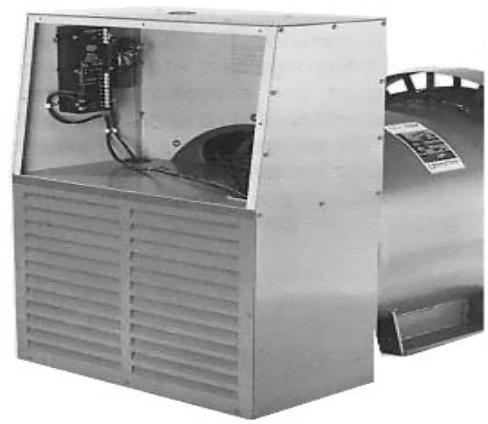

Figure 6-2

2. Disconnect all external wiring from the generator leads inside the conduit box.

3. Remove all conduits or ducting from the conduit box.

4. Attach a suitable hoist to the generator lifting

5. For single bearing generators, remove the bolts mounting the screen assembly to the SAE adapter and remove the screen. (Figure 6-3.)

Figure 6-3

(NOTE: Do not remove the drip cover from the screen assembly if so equipped)Remove the cap screws attaching the drive discs to the flywheel and remove the cap screws attaching the SAE adapter to the flywheel housing.

For two-bearing generators, disconnect the coupling or sheave and belts between the generator and prime mover. (Follow the coupling manufacturer's instructions for direct connection.)

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR

CONDUIT BOX REMOVAL

1. Note the location and markings (re-mark as required) and remove connections from voltage regulator (Figure 6-4), capacitor (Figure 6-5), and any other conduit box mounted controls.

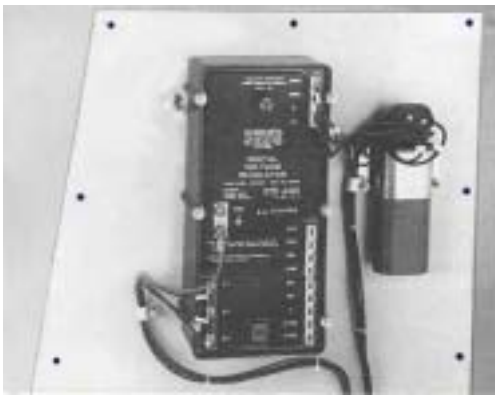

Figure 6-4

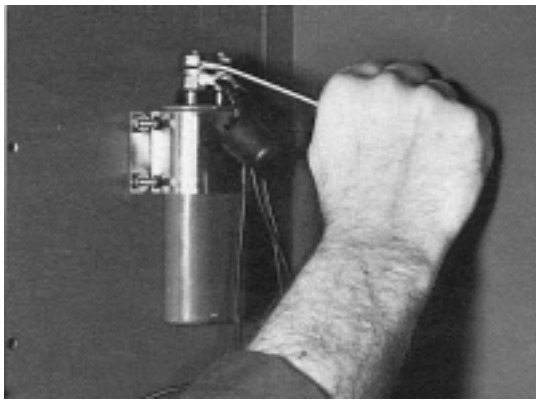

Figure 6-5

2. On generators equipped with bus bars, mark all connections and disassemble main stator (power) leads from the generator side of the bus bars.

3. Remove bolts holding conduit box in place. (Figure 6-6.)

Figure 6-6

4. Remove conduit box. (Figure 6-7).

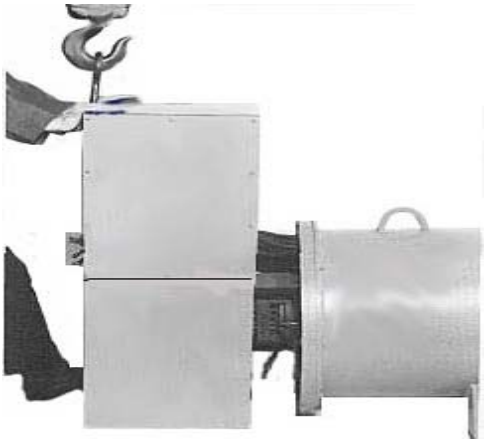

Figure 6-7

EXCITER STATOR (FIELD) REMOVAL

1. Disconnect Fl and F2 leads from the corresponding Fl and F2 terminals on the regulator.

2. Remove all cable ties so the Fl and F2 leads can be removed with the exciter stator. Remove the four cap screws and Belleville washers holding the exciter stator in place. (Figure 6-8.)

Figure 6-8

Remove the exciter stator. Using a lifting strap or fixture. (Figure 6-9.)

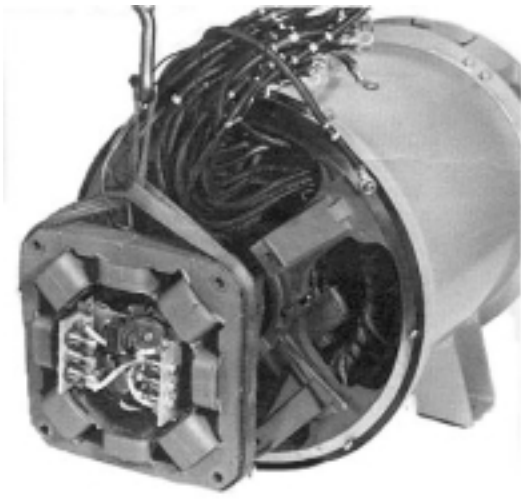

Figure 6-9

EXCITER ARMATURE (ROTOR) REMOVAL

1. Note markings and disconnect the main rotor leads coming out of the lead hole of the aluminum standoff plate from the rectifier aluminum angle. (Figure 6-10.)

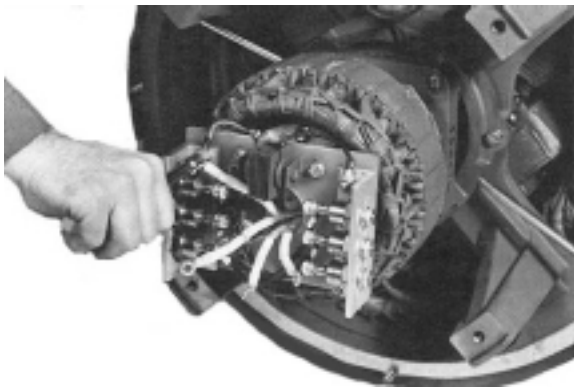

Figure 6-10

2. Remove the cap screw and Belleville washer that holds the exciter (rotor) armature to t generator shaft. (Figure 6-11.)

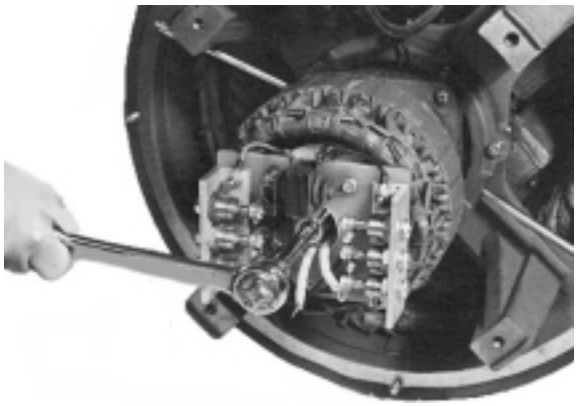

Figure 6-11

3.Use a six inch, 3/4-16NF, cap screw for a puller (See section 9.) The hole that the mounting bolt goes through is threaded. Screw the pull bolt into the hole and it will push against the end of the shaft. (Figure 6-12.)

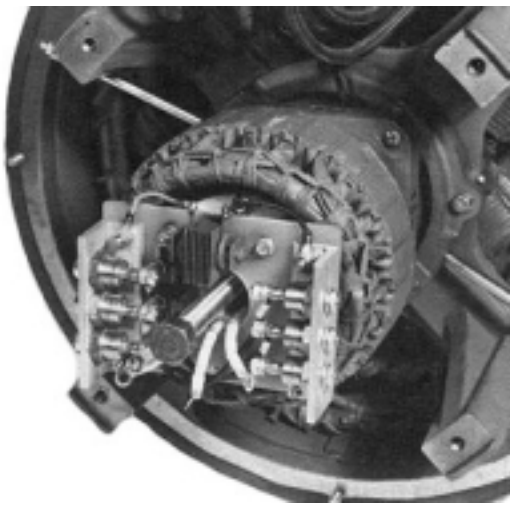

Figure 6-12

Carefully feed the main rotor leads through the hole as the exciter armature is removed. (Figure 6-13.)

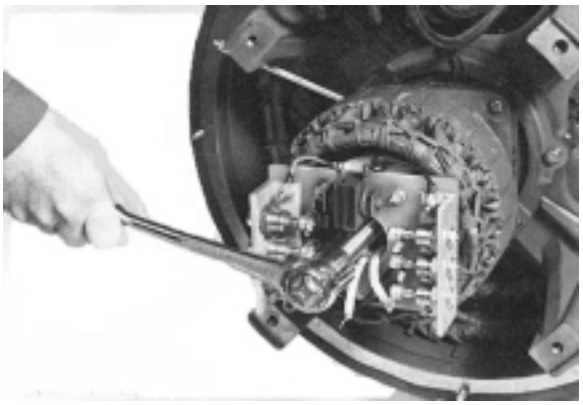

Figure 6-13

CAUTION:
DO NOT TIGHTEN THE PULLER BOLT BEYOND THE END OF THE THREADS. IF A BOLT WITH SUFFICIENT THREAD LENGTH CANNOT BE FOUND, USE A PIECE OF THREADED ROD WITH A NUT WELDED ON THE END.

PMG STATOR REMOVAL

1. Remove exciter armature. (Follow instructions found earlier in this section.)

2. Remove the PMG output leads from the capacitor (Figure 6-14) and loosen all cable ties so the leads can be removed with the PMG stator.

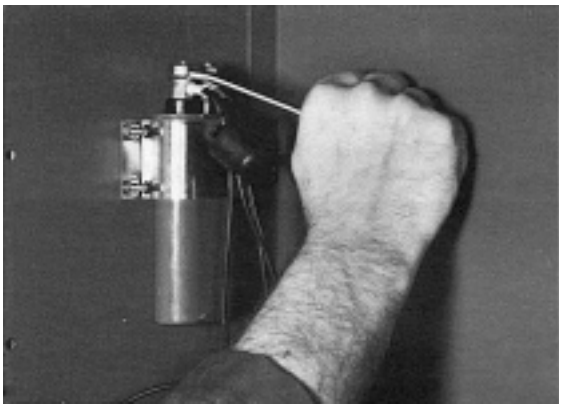

Figure 6-14

3. Note the position of the PMG stator leads that exit at the left inboard side or mark the stator so it can be reinstalled in the same position.

4. Remove the four mounting cap screws. (See Figure 6-15.)

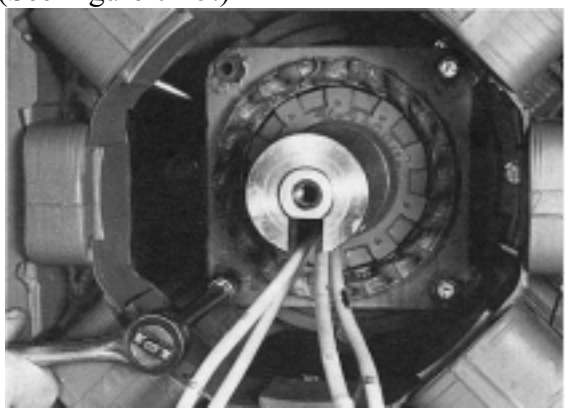

Figure 6-15

5. Carefully remove the PMG stator from its mounting pads and slide over the PMG rotor. The magnets used in the PMG are very strong and will resist removal of the PMG stator. (Figure 6-16.)

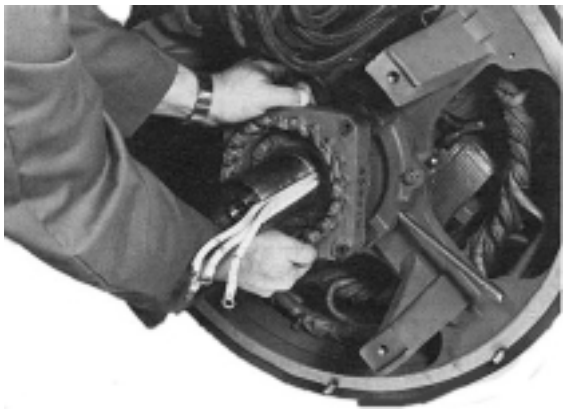

Figure 6-16

PMG ROTOR REMOVAL

1. Remove the exciter armature and PMG stator. (Follow instructions found earlier in this section.)

2. Remove the snap ring that holds the PMG rotor in place on the shaft. (Figure 6-17 and 6-18.)

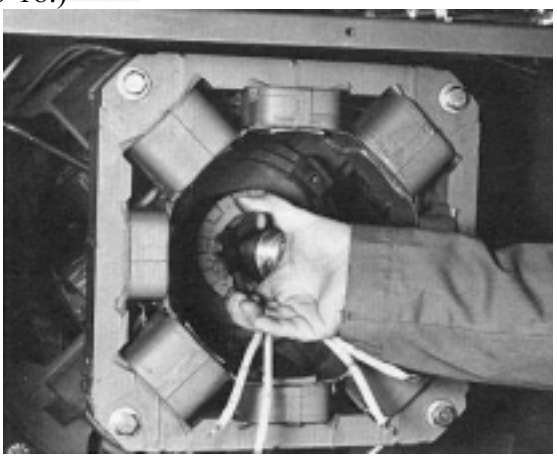

Figure 6-17

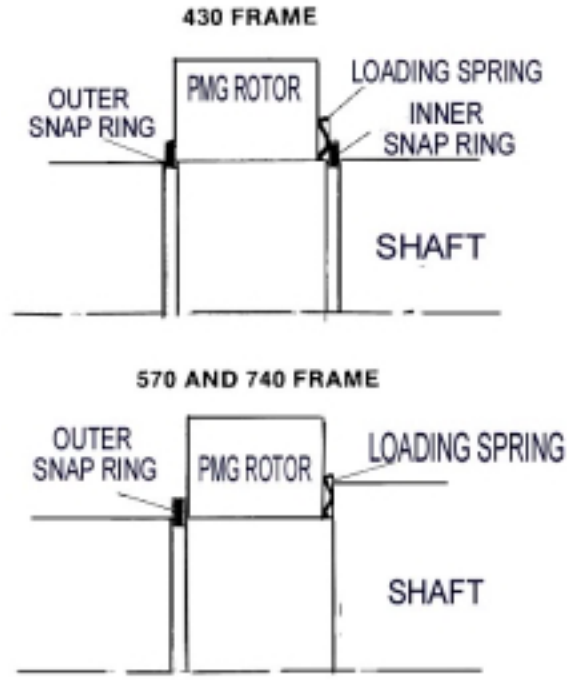

Figure 6-18

3. Slide the PMG rotor off of the shaft. (Figure 6-19.)

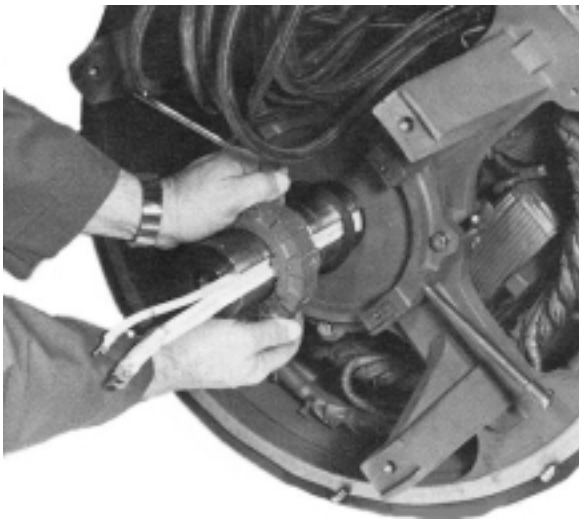

Figure 6-19

4. Remove the loading spring. (if the loading spring is not on the shaft, check to see if it is stuck on the back of the PMG rotor.).

5. On 430 frame generators a second snap ring is used inboard of the PMG rotor. (Larger generators have a step on the shaft.)

This snap ring must be removed before the generator main rotor can be removed. (Figure 6-20.)

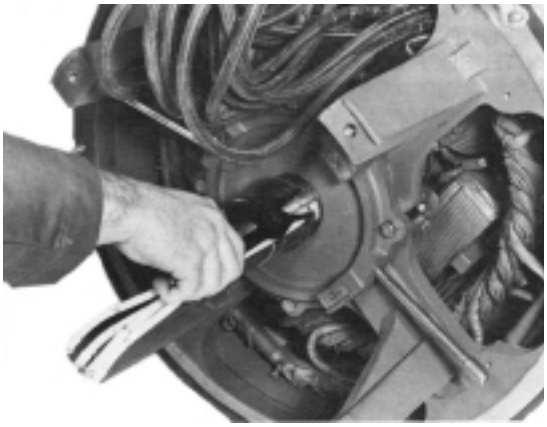

Figure 6-20

MAIN ROTOR REMOVAL

1. Remove the exciter armature and PMG.

2. For single bearing generators, remove the four cap screws holding the bearing caps to the front-end bracket. (Figure 6-21.) Remove the outer cap. (Figure 6-22.)

For two-bearing generators, remove the drive coupling or sheave and key from the shaft extension. Remove the four cap screws holding the bearing lock to the drive end bracket. (Figure 6-23.) Remove the four cap screws holding the bearing caps to the front-end bracket. (Figure 6-21.) Remove the outer cap. (Figure 6-22.)

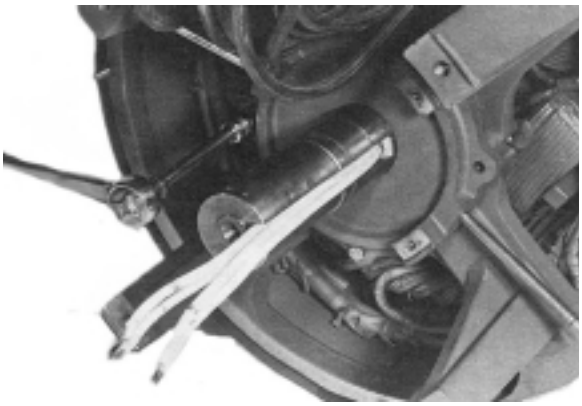

Figure 6-21

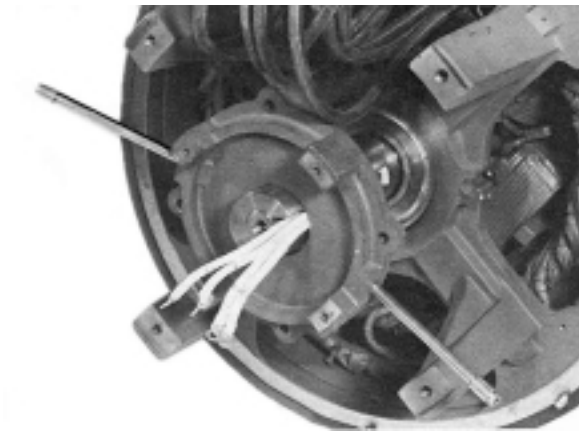

Figure 6-22

Figure 6-23

3. If the screen assembly is still mounted, remove bolts securing the screen assembly to the drive end bracket or the SAE adapter and remove the screen assembly. (Figure 6-24.) (NOTE: Do not remove the drip cover from the screen assembly if so equipped.)

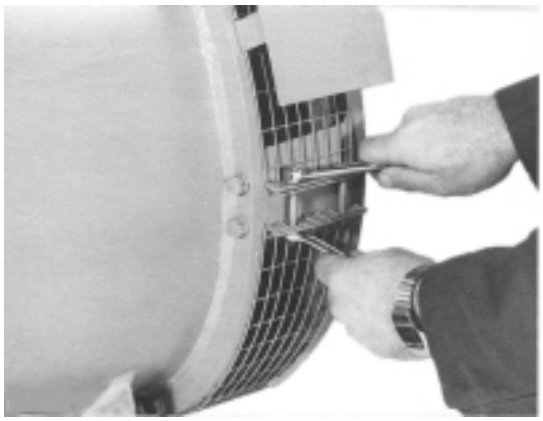

Figure 6-24

4. For single bearing generators, remove the cap screws and hardened washers holding the drive discs to the drive hub. (Figure 6-25.) Remove all drive discs (and spacers if any).

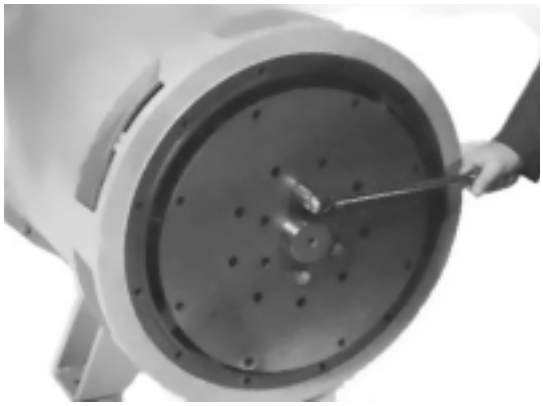

Figure 6-25

5. For single bearing generators, remove the cap screws holding the SAE adapter to the generator and remove the adapter. (Figure 6-26 and 6-27.)

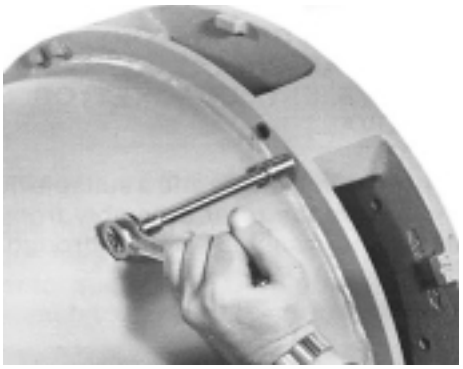

Figure 6-26

Figure 6-27

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN DRIVE END BRACKET OR SAE ADAPTOR REMOVAL

For two bearing generators remove the cap screws holding the drive end bracket to the generator and remove the bracket (Figures 6-26 and figure 6-28)

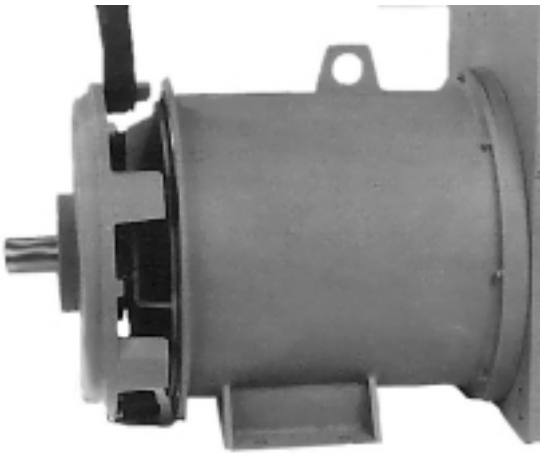

Figure 6-28

6. Using a rotor lifting fixture and a suitable hoist, carefully remove the rotor assembly from the main stator and frame assembly through the drive end. (Figure 6-29.)

CAUTION:
SPECIAL CARE SHOULD BE TAKEN WHEN REMOVING THE MAIN ROTOR, WINDING DAMAGE COULD RESULT IF THE ROTOR IS ALLOWED TO HIT THE MAIN STATOR.

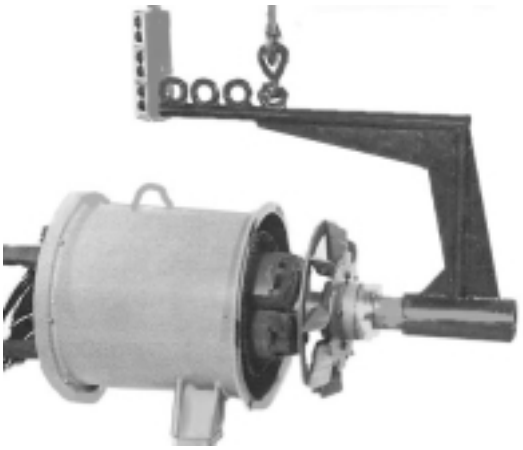

Figure 6-29

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

FRONT END BRACKET REMOVAL

1. Remove front bracket mounting screws. (Figure 6-30.)

2. Remove the front-end bracket from the main stator assembly. (Figure 6-31.)

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE FRONT END BRACKET REMOVAL

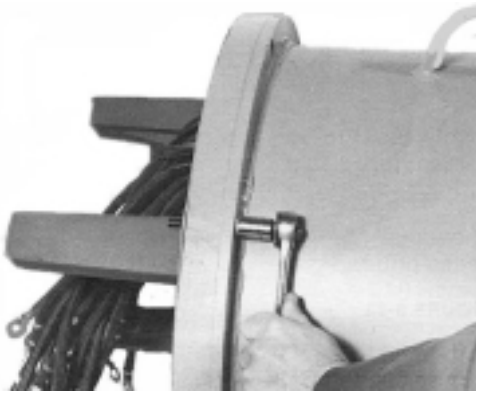

Figure 6-30

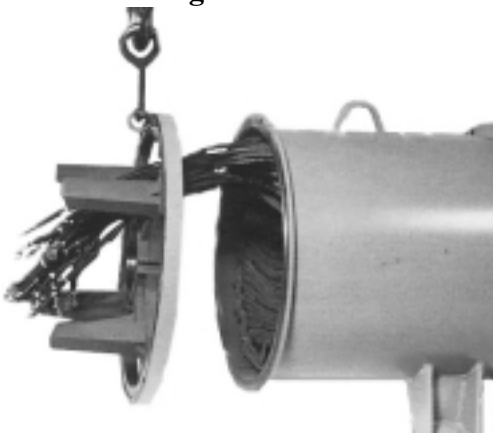

Figure 6-31

EXCITER INSPECTION

EXCITER STATOR

1. Clean dust and dirt from the exciter stator winding. (Figure 6-32.) (See section 5.)

Figure 6-32

2. Check the exciter stator for a loose, frayed, or burnt winding. Measure winding resistance and insulation resistance. (See section 8.)

Repair or replace as necessary. If field repair of the winding is necessary, contact Katolight for special winding procedures and materials.

3. Look for score marks in the bore of the exciter core caused by rubbing. (This could indicate bearing or assembly problems and should be investigated.)

EXCITER (ROTOR) ARMATURE

1. Clean dust and dirt from and rectifier assembly. (Figure 6-33) (See Section 5)

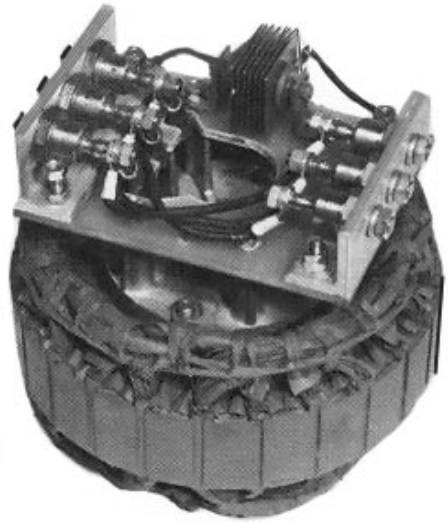

Figure 6-33

2. Check the exciter armature for burrs on the mating surfaces.

3. Check the rectifiers and surge protector for proper operation. Replace defective parts.

CAUTION: THREE FORWARD AND THREE REVERSE POLARITY DIODES ARE USED. BE SURE THE CORRECT PART IS INSTALLED IN THE CORRECT LOCATION. THE SURGE SUPRESSOR IS POLARIZED. OBSERVE POLARITY MARKINGS WHEN CHANGING THE SURGE SUPRESSOR

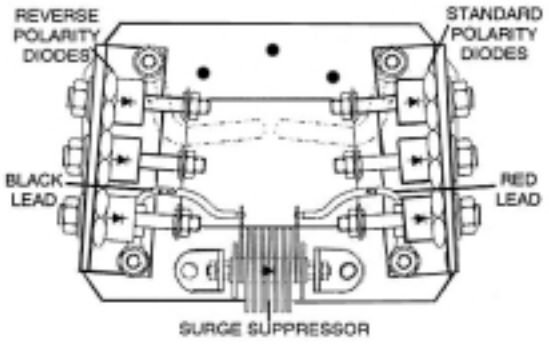

Figure 6-34

Torque mounting nuts to 80 in-lb. Torque lead terminal nuts to 25 in-lb. Never torque against the diode terminal - use a 7/16-in. wrench to support the terminal.

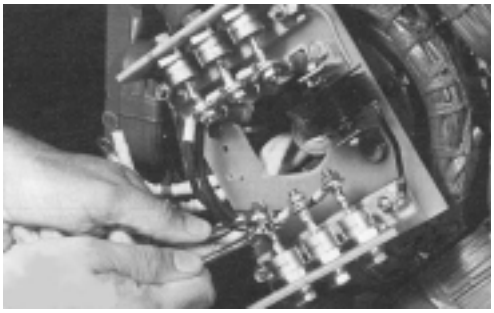

Figure 6-35

4. Check the exciter armature and rectifier assembly for loose, frayed, or burnt winding or loose connections. Measure winding resistance and insulation resistance. DO NOT megger diodes or surge suppressor. Repair or replace as necessary. If field repair of the winding is necessary, contact Katolight for special winding procedures and materials.

5. Look for score marks on the outside diameter of the armature core caused by rubbing. (This could indicate bearing or assembly problems and should be investigated.)

PMG INSPECTION

PMG STATOR

1. Clean dust and dirt from the PMG stator winding.

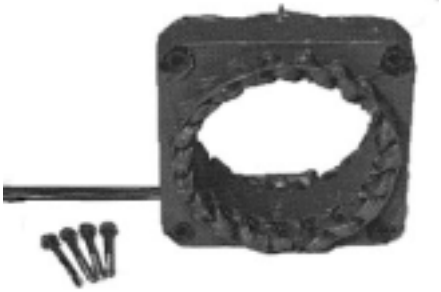

Figure 6-36

2. Check PMG stator for a loose, frayed, or burnt winding. Measure winding resistance and insulation resistance. (See section 8.) Repair or replace as necessary. Contact Katolight for special winding procedures and materials.

3. Look for score marks in the bore caused by rubbing.

PMG ROTOR

WARNING
THE PMG ROTOR USES VERY STRONG MAGNETS. KEEP AWAY FROM IRON AND STEEL PARTS THAT COULD BE DRAWN TO THE MAGNETS AS WELL AS OTHER COMPONENTS THAT CAN BE DAMAGED BY MAGNETIC FIELDS.

Figure 6-37

1. Clean dust and dirt from the PMG rotor.

2.Check to be sure all magnets are tightly bonded to the PMG rotor.

3.Check the bore and keyway of the PMG rotor for burrs or corrosion.

4.Look for score marks on the outside diameter caused by rubbing. (This could indicate bearing or assembly problems and should be investigated.)

5. Inspect snap rings and loading spring, replace as required.

MAIN ROTOR INSPECTION

BEARING

1. Check the bearing for damage or wear. Clean old grease from the bearing cap, and fill bearing cap grease cavity 1/3 to 1/2 full of r Chevron SRI (or equivalent).

CAUTION: If the bearing needs to be removed any reason, always install a new bearing.

2. If the bearing is to be replaced, remove with suitable puller. (Figure 6-38.)

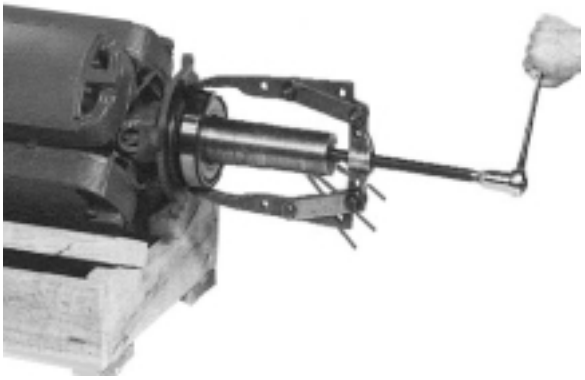

Figure 6-38

3.Be sure the inner bearing cap is on the shaft before installing the new bearing.

4. Heat the new bearing in an oven to a maximum temperature of 212°F (100°C). Apply a thin coat of clean lubricating oil to the press-fit area of rotor shaft. Install the bearing over the end of the shaft until it seats against the shaft shoulder as shown in Figure 6-39. The bearing should slide on the shaft and seated without excessive force. If the bearing binds on the shaft before being fully seated a piece of tubing, slightly larger than the press area, can be used to drive the bearing into place. Using light taps with a soft mallet, apply pressure to the inner race only.

CAUTION:
UNDER NO CIRCUMSTANCES SHOULD PRESSURE BE APPLI ED TO THE OUTER RACE OF THE BEARING, AS PERMANENT BEARING DAMAGE COULD RESULT.

Figure 6-39

Allow the bearing to cool for one hour before attempting to assemble the generator.

FAN

1. Check the fan for cracks or broken blades. Replace the fan if defective.

2. Mark the hub and fan for alignment, this is necessary to be sure the balance weights will be in the same position when the fan is reinstalled.

3. For single bearing generators. Remove the fan mounting cap screws (Figure 6-40) and slide the fan off the shaft. (Figure 6-41.) For two-bearing generators, remove the drive end bearing and bearing cap. (See bearing removal instructions.) Remove the fan mounting cap screws and slide fan off the shaft. (Figure 6-40 and 6-41.)

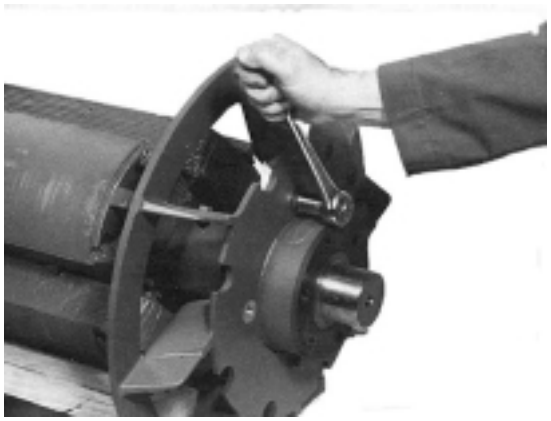

Figure 6-40

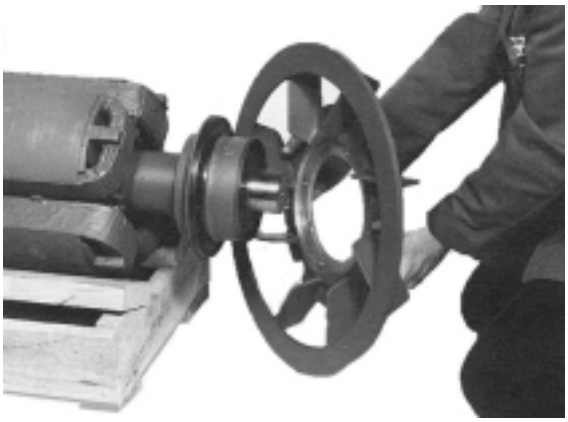

Figure 6-41

4. To reinstall, slide the fan on the shaft making sure the fan-mounting surface is toward the drive hub. Align reference marks (this is important for assembly balance) and mount the fan to the drive hub with the cap screws and Belleville washers. (Figure 6-42.) Torque the cap screws to 60 ft-lb. (81 N-m).

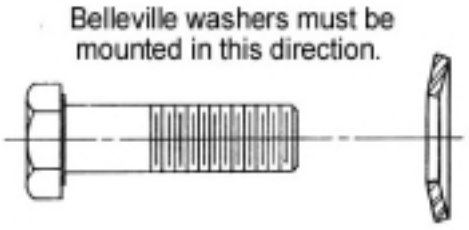

Figure 6-42

5. NOTE: Balance weights on the fan are for balance of the complete rotor assembly. The rotor assembly should be rebalance if a new fan has been installed.

6. On two-bearing generators, install bearing cap and new bearing according to the bearing assembly instructions. (Item A.)

Drive Hub (Single Bearing Generators)

1. Check the drive hub for cracks or stripped drive disc mounting holes. Replace the hub if defective.

2. If the hub is to be replaced, remove the fan (See Item B) and install a suitable puller to the hub. Remove the two set screws in the hub over the key. Using a torch, rapidly heat the hub at the outer diameter while tightening the puller. (This must be done rapidly before the heat can expand the shaft.) Remove the hub. (Figure 6-43)

Figure 6-43

3. To insure proper fan location, mark the new hub in the same place as the old hub relative to the keyway. Install key in shaft. Heat the new hub in an oven to 500°-600°F (260°-316°C). Use suitable heat resistant gloves, slide the hub over the key in the shaft until it seats against the shaft shoulder. (Figure 6-44.)

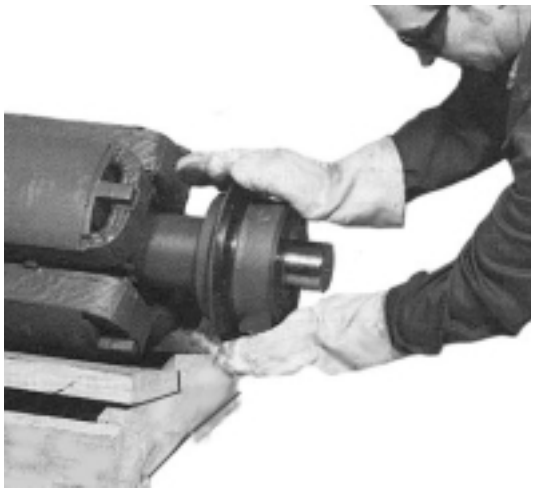

Figure 6-44

4. Allow the hub to cool for one hour. After the hub has cooled, tighten the set screws in the hub to 50 ft-lbs. (68 N.M.) torque. Match the alignment marks on the fan and hub and mount the fan. (See item B.)

5. Rebalancing the rotor assembly is not necessary if only the hub is replaced and the fan is mounted in the same location relative to the hub and shaft.

MAIN ROTOR CORE AND WINDINGS

1. Clean all parts. Remove dust and dirt from the rotor winding air passages with low-pressure, moisture-free air.

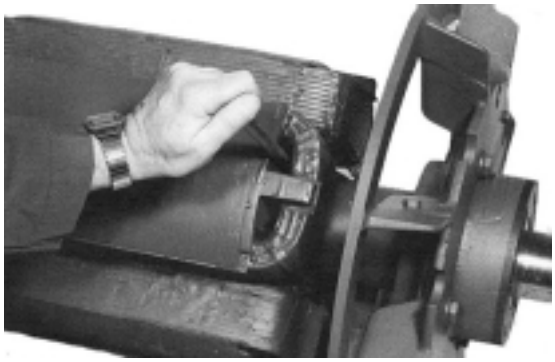

Figure 6-45

2. Check the rotor for loose, frayed, or burned windings. Measure winding resistance an insulation resistance. Test for shorted turns using an A-C impedance test A defective rotor winding must be rewound The rotor assembly must be rebalanced after any rework or repair has been completed.

DRIVE DISCS (SINGLE BEARING GENERATORS ONLY)

1. Inspect the drive discs for distorted or bent edges. (Figure 6-46) Inspect for worn mounting holes. Replace all defective discs as necessary.

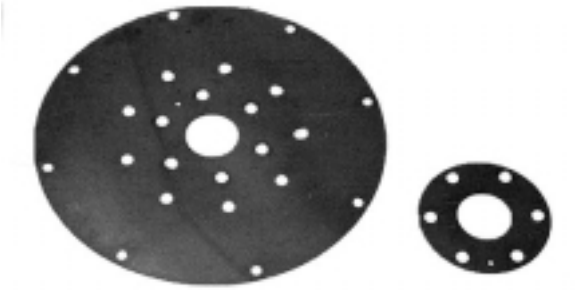

Figure 6-46

2. Inspect the drive disc mounting cap screws for damaged threads. Replace cap screws if damaged.

FRONT (EXCITER) END BRACKET INSPECTION

1. Remove the filler and drain grease pipes and the grease plugs from outer bearing cap. (Figure 6-47.)

Figure 6-47

2. Clean the end bracket, outer bearing cap, grease pipes, and cap screws to remove all dust, dirt, and grease.

3. Inspect the cap screws for stripped threads and replace if defective.

4. Inspect the end bracket for stripped threads, cracks, and burred or rough mating surfaces. Inspect the bearing bore for burrs or wear. If the bracket shows excessive bearing bore wear, it should be repaired or replaced. (Figure 6-48.)

Figure 6-48

5. Inspect the mounting pads for the PMG stator and exciter stator. Be sure they are smooth, clean, and free of any burrs or rust. That could interfere with proper alignment. (Figure 6-47 and 6-48.)

6. Re-assemble the grease pipes and fittings to the bearing cap.

DRIVE END BRACKET OR SAE ADAPTER INSPECTION

1. For two-bearing generators, remove the grease plugs from the bracket.

2. Clean the bracket or adapter, cap screws and screen assembly to remove all dust, dirt, and grease.

3. Inspect the cap screws for stripped threads and replace if defective.

4. Inspect the bracket or adapter for stripped threads, cracks, and burred or rough mating surfaces. (Figure 6-49 and 6-50.)

Figure 6-49

Figure 6-50

5. For two-bearing generators, inspect the bearing bore for burrs or wear. If the drive end bracket shows excessive bearing bore wear, it should be repaired or replaced.

MAIN STATOR INSPECTION

1. Clean dust and dirt from the stator frame and winding. (Figure 6-51.) (See section 5.)

Figure 6-51

2. Inspect the frame for stripped threads, cracks, burred mating surfaces, or other damage.

3. Inspect the stator for a loose, frayed, or burnt winding. Measure winding resistance and insulation resistance. (See section 8.) Repair or replace as necessary.

FRONT END BRACKET INSTALLATION

1.Install two guide pins (threaded rod can be used) into the generator side of the end bracket mounting holes. Align the guide pins with the holes in the generator frame and slide the bracket onto the frame. (Figure 6-52.) Install bracket mounting cap screws. (Figure 6-53.)

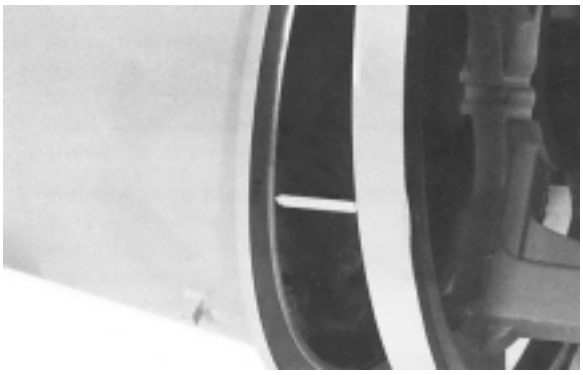

Figure 6-52

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE FRONT END BRACKET INSTALLATION.

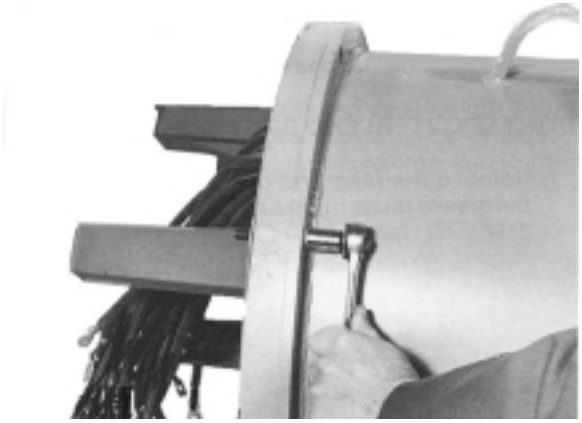

Figure 6-53

2. Remove the two guide pins and insert the remaining cap screws and torque to specifications given in section 12.

MAIN ROTOR INSTALLATION

1. Grease bearing cavity and bearing with Chevron SRI (or equivalent) grease.

2. Using a rotor lifting fixture and a suitable hoist, carefully install the rotor assembly into the main stator assembly through the drive end. (Figure 6-54.) Carefully feed the rotor leads through the front-end bracket shaft hole as the rotor is installed.

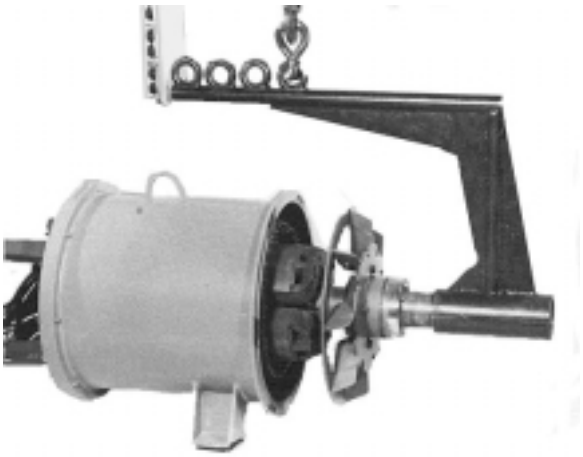

Figure 6-54

CAUTION:
SPECIAL CARE SHOULD BE TAKEN WHEN INSTALLINGTHE ROTOR ASSEMBLY. WINDING DAMAGE COULD RESULT IF THE ROTOR IS ALLOWED TO HIT THE MAIN STATOR.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

3. For single bearing generators, slide the SAE adapter over the fan and secure to the main stator and frame assembly with cap screws torqued per section 12. (Figure 6-55 and 6-56.) It may be necessary to raise the rotor assembly slightly to allow the mounting of the SAE adapter.

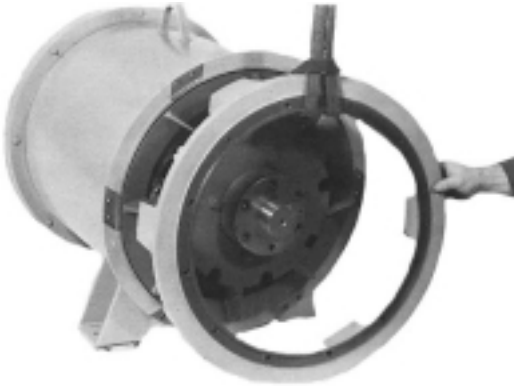

Figure 6-55

Figure 6-56

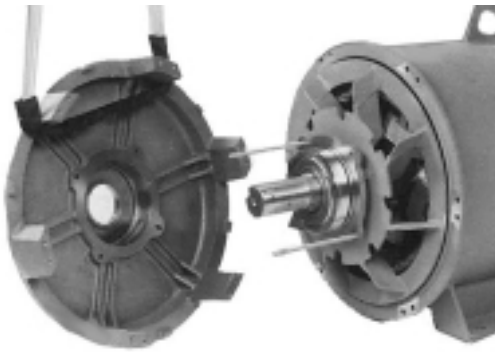

Figure 6-57

For two-bearing generators, insert two guide pins in the rear bearing lock holes. (Figure 6-57.) Fill the grease cavity of the drive end bracket 1/3 to 1/2 full of Chevron SRI (or equivalent) grease. Assemble all grease plugs in the bracket. Mount the bracket on the bearing and guide the bearing lock pins through the bracket holes. (Figure 6-58.)

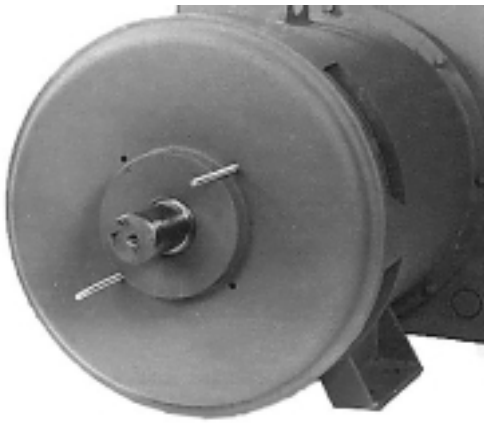

Figure 6-58

Align the drive end bracket and mount with the cap screws. (Figure 6-59.) Insert two cap screws with lock washers into the bearing lock and tighten. Remove the guide pins and replace with the remaining two cap screws with lock washers. Torque bearing cap screws to 25 lb.-ft (34 NM). Torque bracket mounting cap screws per specifications given in section 12.

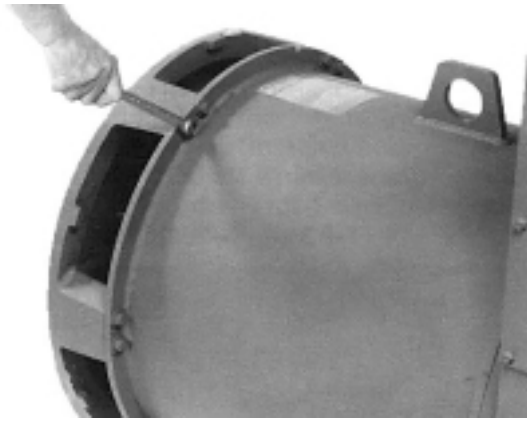

Figure 6-59

CAUTION:
ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TOASSIST IN THE DRIVE END BRACKET OR THE SAE ADAPTER ASSEMBLY.

4. For single bearing generators, insert a guide stud into the drive hub. Position all spacers (if any), then all drive discs, one at a time until all discs are installed. (Figure 6-61.)

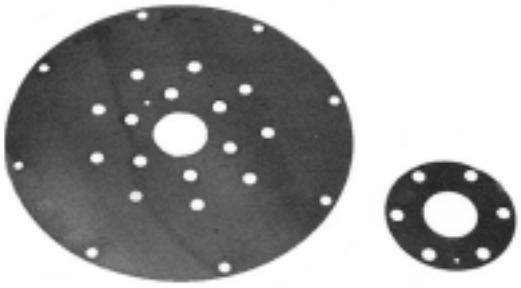

Figure 6-61

Make sure that all disc mounting holes at the inner and outer diameter are properly aligned. Secure the discs with the grade eight 5/8-18 cap screws and hardened washers. Torque to 192 ft-lb. (260 N-m). Torque the bolts in sequence according to Figure 6-62.

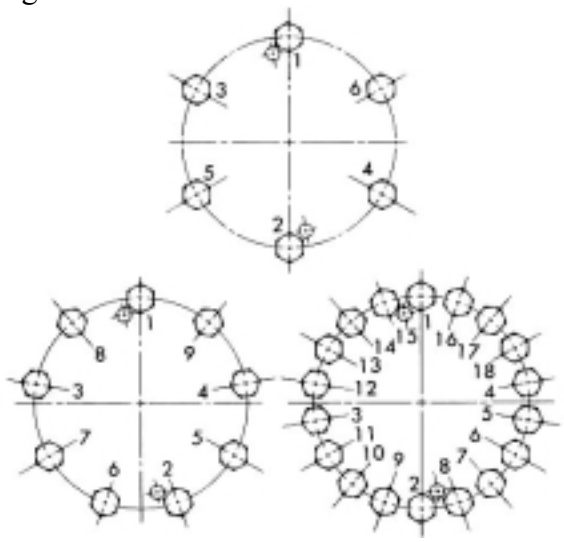

Figure 6-62

5. Install the outer bearing cap on the exciter end. (Figure 6-63.) Align holes in inner and outer bearing cap and install cap screws. Torque to 25 lb.-ft (34 N-M) (Figure 6-64.)

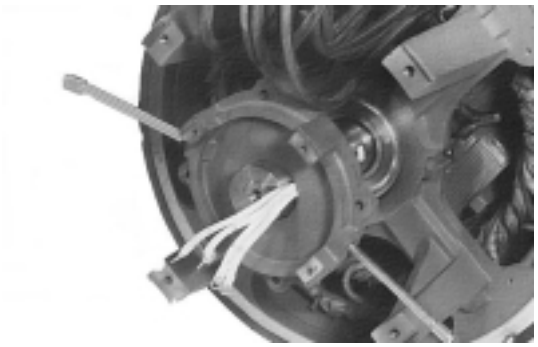

Figure 6-63

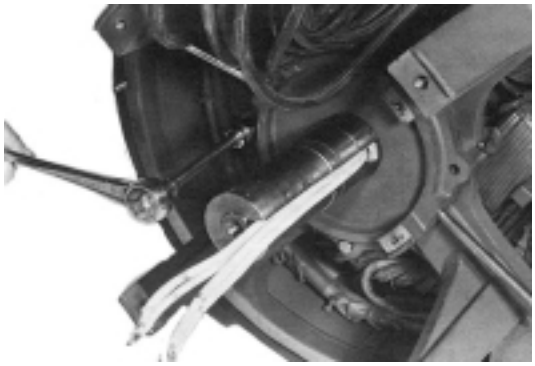

Figure 6-64

PMG INSTALLATION

1. Install inboard snap ring, where supplied, and loading spring on shaft. (Figure 6-65.)

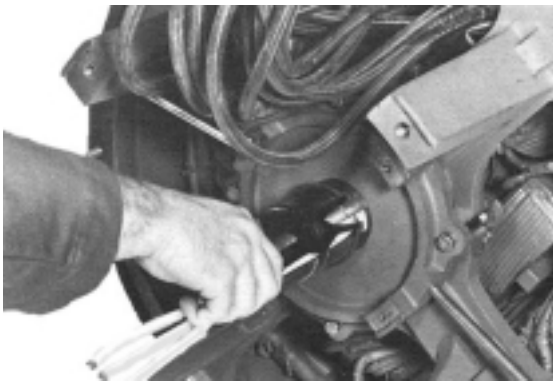

Figure 6-65

2. Slide PMG rotor onto shaft. (Figure 6-66.)

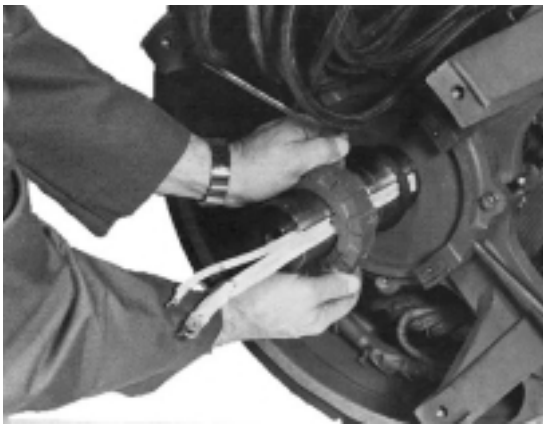

Figure 6-66

3. Install snap ring. (Figure 6-67.) Use a piece of pipe slightly larger than the shaft (2-3/4 inches) to push the rotor back against the loading spring until the snap ring seats in the slot. (Figure 6-68.)

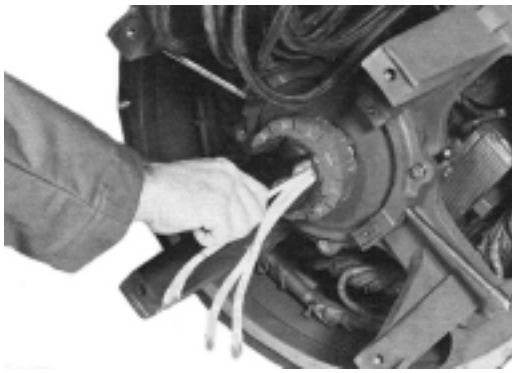

Figure 6-67

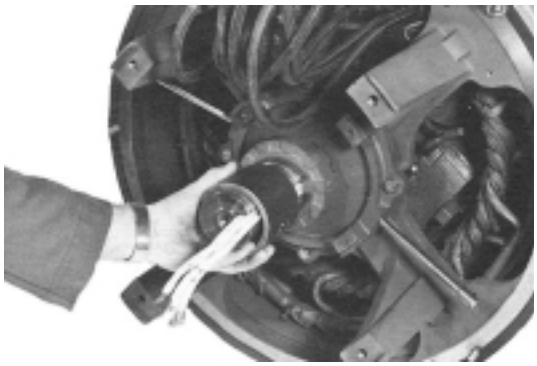

Figure 6-68

4. Install the PMG stator on its mounting pads, with the leads in the left (9:00 o'clock) inboard position, and secure with the four

mounting cap screws and Belleville washers. (Figure 6-69 and 6-72.)
Torque to 4 ft-lb. (5 N-M).

Figure 6-69

5. Route and secure PMG moving parts.

EXCITER INSTALLATION

1. Attach a wire to the main rotor leads and feed the wire through the armature bore and the lead hole in the aluminum standoff plate. On larger exciters, it will be helpful to install a guide pin in the end of the shaft to support the armature while fishing the rotor leads through. (Figure 6-70.)

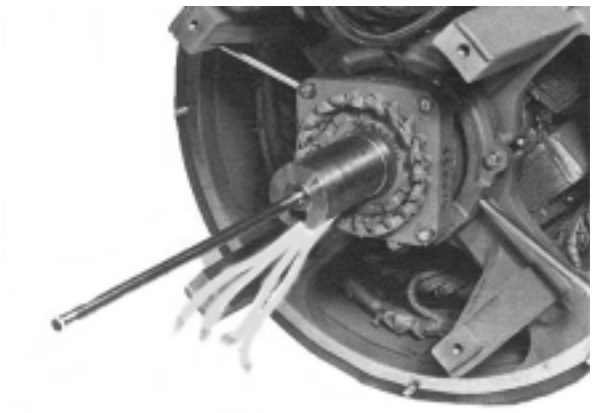

Figure 6-70

Align the key in the armature bore to the keyway in the shaft. Slide the armature on the shaft while feeding the main rotor leads through the lead hole in the aluminum standoff plate. (Figure 6-71.)

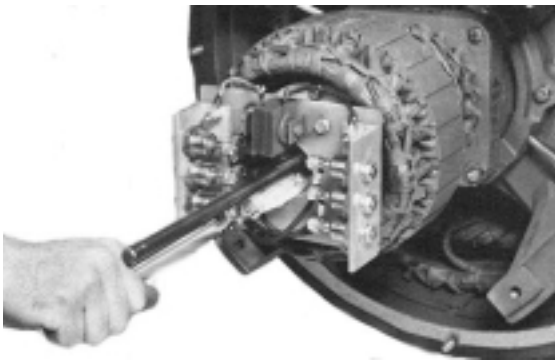

Figure 6-71

Insert the cap screw and Belleville washer (Figure 6-72.) through the mounting hole in the aluminum standoff plate and secure to the shaft (Figure 6-73). Tighten the cap screw until the armature seats on the shaft. Torque to 84 lb.-ft (114 N-M).

Figure 6-72

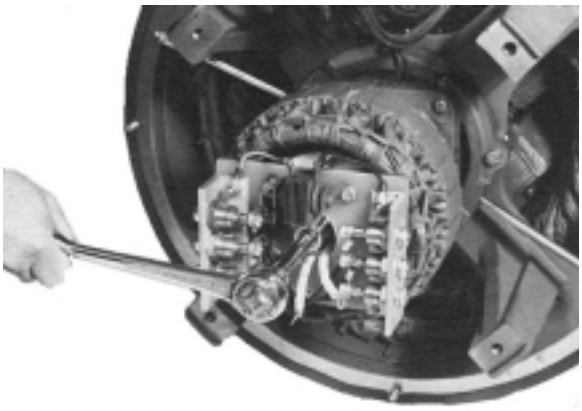

Figure 6-73

2. Observe the polarity markings and connect the main rotor leads to the rectifier

assembly. (Figure 6-74.) Torque the nuts to 4 ft-lb. (5.4 N-M).

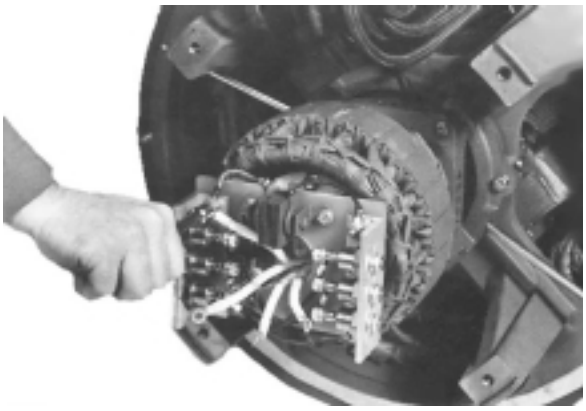

Figure 6-74

3. Position the exciter field leads at the left (9:o'clock) inboard position. Using a suitable lifting device, mount the exciter stator on the front e bracket mounting pads and align the mounting holes. (Figure 6-75.) Mount the cap screws with Belleville washers. (Figure 6-72.) Torque t cap screws to 60 ft-lb. (81 N-M). Route and secure the exciter stator leads away from any moving parts.

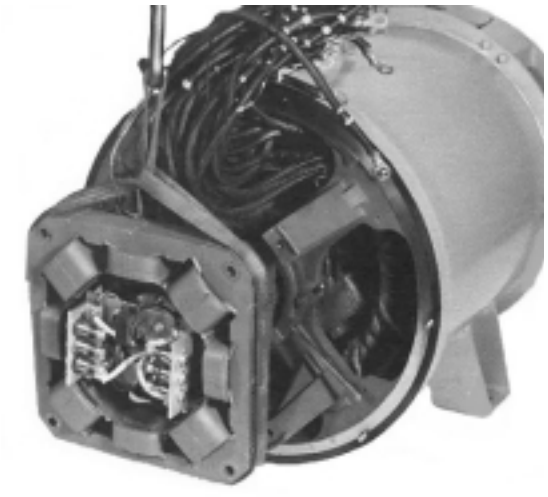

Figure 6-75

CONDUIT BOX INSTALLATION

1. Install the conduit box over the main stator leads (be sure the leads are in the upper compartment and secure with bolts and lock washers. (Fig 6-76 and 6-77.)

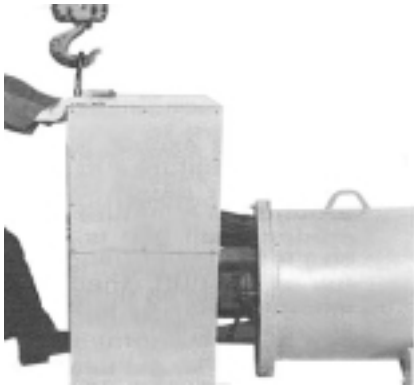

Figure 6-76

Figure 6-77

2. On generators with bus bar assemblies, reassemble main stator leads and insulating blocks to bus bars. (Figure 6-78.)

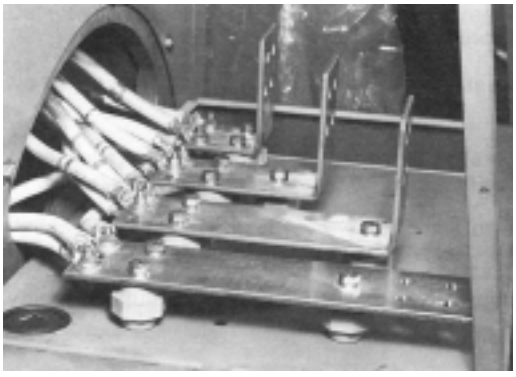

Figure 6-78

3. Reconnect exciter leads, PMG leads and other accessories according to the connection prints and markings installed before disassembly.

ASSEMBLY TO PRIME MOVER

1. Attach a suitable hoist to the generator lifting lugs, and move the generator until the generator foot mounting holes are aligned with the base and slightly above.

2. For single bearing generators, if the screen assembly is mounted on the adapter, remove the mounting bolts and remove the screen. (Figure 6-79.)

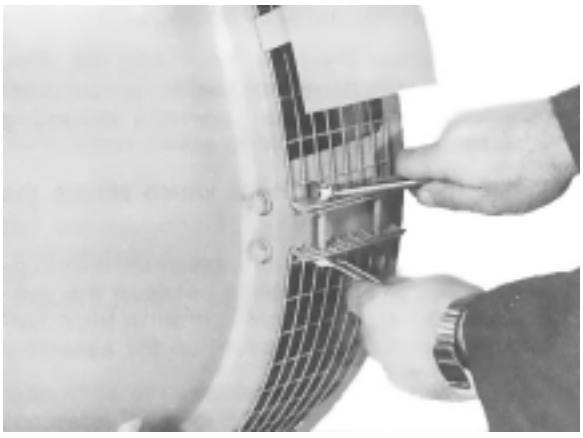

Figure 6-79

(NOTE: Do not remove the drip cover from the screen assembly if so equipped.) Insert two guide pins in the flywheel and two in the flywheel housing. Adjust the generator position until the drive discs are piloted in the flywheel. Remove the guide pins and secure the discs with Grade 8 place bolts and hardened washers or Grade 8 cap screws and heavy series lockwashers.

Torque per specifications given in section 12.

Position the generator so that the SAE adapter mates with the flywheel housing.

WARNING
DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJUY OR EQUIPMENT DAMAGE.

CAUTION:
DO NOT FORCE THE ALIGNMENT OFTHE UNITS. SHIFT THE GENERATOR FROM SIDE TO SIDE OR RAISE OR LOWER WITH A LIFTING DEVICE AS NECESSARY.

It may be necessary to use shims under the mounting feet of either the generator or the prime mover to obtain proper alignment. Use the same shims as removed under disassembly or proceed as follows: Using the extreme bottom four cap screws, mount the SAE adapter to the flywheel housing.

With a .0015 to .002 inch feeler gauge at the extreme top of the adapter to flywheel housing fit, raise the generator or lower the prime mover until the gauge is snug. Relieve just enough to release the feeler gauge and torque the remaining SAE adapter cap screws to the flywheel housing.

Mount the screen assembly and tighten the mounting bolts.

For two-bearing generators, align the coupling halves or sheaves between the generator and the prime mover by adding shims under the feet.

3. Shim under the generator feet for proper support, ensuring that the generator mounting surfaces are level.

4. Install the mounting bolts that secure the generator to the base.

5. For two bearing generators, assemble the coupling halves or sheave belts between the generator and the prime mover. (Follow the coupling manufacturer's instructions for assembly and alignment.)

6. Connect all conduits and ducting to the conduit box.

7. Connect all external wiring to the generator inside the conduit box.

8. Check the exciter air gap (the gap between exciter armature and stator) by inserting a .010 inch feeler gauge in the gap and rotating around the armature diameter to ensure the minimum air gap is available. (See Figure 80.) If the feeler gauge cannot be rotated full revolution, then check for a "cocked" exciter stator or loose stator mounting screws.

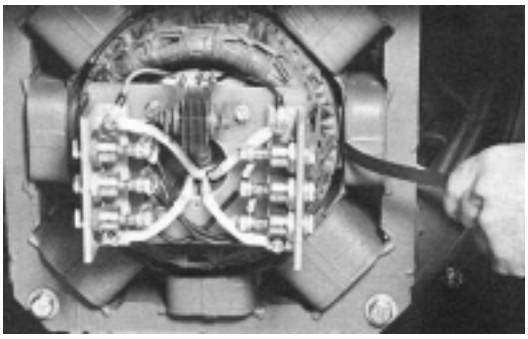

Figure 6-80

NOTE: On single bearing units, the exciter air gap cannot be checked properly until the generator is mounted to the prime mover.

9. Install the conduit box covers.

TROUBLESHOOTING

INTRODUCTION

This section is intended to suggest a systematic approach to locating and correcting generator or regulator malfunctions. The sections are arranged according to the symptoms of the problem. The steps in each section have been arranged in an attempt to do the easy checks first then to prevent further damage when troubleshooting a disabled machine.

The first and perhaps most important step of troubleshooting should be to gather as much information as possible from personnel who may have been present during the failure. Information on how long the generator had been running, what loads were on the line, weather conditions, what protective equipment operated, etc., can help isolate the problem.

Always make a thorough visual inspection to check for any obvious problems before attempting to run the generator.

WARNING
HIGH VOLTAGES CAN BE PRESENT AT THE GENERATOR AND REGULATOR TERMINALS. HIGH RESIDUAL VOLTAGES CAN BE PRESENT EVEN WITH THE REGULATORDISCONNECTED OR ITS FUSES REMOVED. SOME EQUIPMENT (SUCH AS SPACEHEATERS) MAY BE ENERGIZED WHEN THE GENERATOR IS OFF. TOOLS, EQUIPMENT, CLOTHING, AND YOUR BODY MUST BE KEPT CLEAR OF ROTATING PARTS AND ELECTRICAL CONNECTIONS.

SPECIAL CAUTION MUST BE TAKEN DURING TROUBLESHOOTING SINCE PROTECTIVE COVERS AND SAFETY DEVICES MAY BE DISABLED TO GAIN ACCESS AND MAKE TESTS.

BE CAREFUL. SERIOUS PERSONAL INJURY OR DEATH CAN RESULT FROM THESE HAZARDS. CONSULT QUALIFIED PERSONNEL WITH ANY QUESTIONS.

SYMPTOM:		
NO VOLTAGE OR RESIDUAL VOLTAGE	Regulator Fuse Blown Check fuse with ohmmeter.	Replace bad fuse.
	Voltmeter Off	Check to be sure meter phase selector switch is not in the off position.
	Defective Voltmeter	Verify proper operation of panel meter with another meter that is known to be accurate.
	Incorrect Connections	Verify generator connections.
	Defective Connections/Wiring	Inspect all wiring for grounds, open circuits & short circuits.
	No Regulator Input	Measure voltage at regulator input (PMG output)
	Defective Diodes, Surge Suppressor	Test generator with constant excitation (12 volt battery test) refer or Generator Windings
	Voltage Regulator Protective Shutdown Circuits are Operating	Correct problem and adjust regulator. Refer to regulator manual.
	Voltage Regulator Inoperative	Adjust or replace regulator. Refer to regulator manual.

LOW VOLTAGE - NO LOAD	Under speed Operation	Check speed using tachometers and/or frequency meters.
	Defective Voltmeter	Verify operation of panel meter with another meter that is known to be accurate.
	Residual Voltage	Disconnect Fl and F2 leads at the voltage regulator. If voltage goes down continue on to next step, if voltage does not change refer to troubleshooting for symptoms of "No Voltage - No Residual Voltage".
	Incorrect Generator Connections	Verify generator connections refer to drawings supplied V generator set and section 3.
	Defective Connections / Wiring	Inspect all wiring for grounds, open circuits, short circuits, and loose and dirty connections.
	Regulator Adjustments	Adjust regulator. Refer to regulator manual. Check exciter field volts.
	Defective Diodes, Surge Suppressor, Generator Windings	Test generator with constant excitation (12 volt battery test)
	Voltage Regulator not Operating	Adjust or replace regulator. Refer to regulator manual. Properly

LOW VOLTAGE WHEN LOAD IS APPLIED	Overload	Measure amps and verify that the load does not exceed nameplate rating of the generator
	Defective Ammeter	Verify operation of ammeter by using a separate meter known to be accurate
	Droop Circuit	If the generator set is equipped for paralleling, some voltage droop is normal as load increases. Refer to the regulator instruction manual
	Continue troubleshooting for symptoms “Generator Produces Low Voltage - No Load”.	Continue troubleshooting for symptoms “Generator Produces Low Voltage - No Load”.
HIGH VOLTAGE	Defective Voltmeter	Verify operation of panel meter with another meter that is known to be accurate
	Incorrect Operating Speed	Verify speed with tachometer or frequency meter.
	Incorrect Connections	Verify generator connections Refer to drawings supplied with generator set
	Defective Connections / Wiring	Inspect all wiring for grounds, open circuits, and short circuits.
	Regulator Adjustments	Adjust regulator. Refer to regulator manual
	Diode Polarity Incorrect	Check diodes, verify proper diodes are installed and polarity is correct.
	Voltage Regulator not Operating	Adjust or replace regulator. Refer to regulator instruction manual.

VOLTAGE IS FLUCTUATING	Incorrect Speed	Verify speed with tachometer or frequency meter.
	Unstable Speed	Verify governor stability.
	Voltage Regulator Stability	Adjust regulator stability. Refer to regulator manual.
	Defective / Loose Connections	Inspect all wiring for loose or dirty connections.
	Defective Diodes, Surge Suppressor or Generator Windings	Test generator with constant excitation (12-volt battery test).
	Remote Voltage Adjust	Check operation. Refer to regulator manual.
	Defective Regulator	Replace regulator. Refer to regulator manual.
OPERATES SATISFACTORILY WHEN COLD, BUT SHUTS DOWN WHEN WARM	Regulator Shutdown on Over Temperature	Correct cooling problems. Refer to regulator manual.
BUILDS VOLTAGE FROM STARTUP,THEN GOES TO LOW (RESIDUAL) VOLTAGE	Regulator Protective Circuit is Operating	Check indicators on regulator. Correct problems and adjust as required. Refer to regulator manual.
EQUIPMENT RUNS NORMALLY ON UTILITY POWER, BUT WILL NOT RUN ON GENERATOR SET	Voltage Waveform is Distorted	Analyze load. Excessive SCR (Thyristor) loading will cause distortion. Some equipment may be sensitive to distorted waveforms. Refer to Katolight.

GENERATOR TESTING

VISUAL INSPECTION

Whenever testing and troubleshooting a generator set, it is always a good practice to make a thorough visual inspection. Remove covers and look for any obvious problems. Burnt windings, broken connectors, leads, mounting brackets, etc., can usually be identified. Look for any loose or frayed insulation, loose or dirty connections, broken wires. Be sure all wiring is clear of rotating parts.

Verify that the generator is connected for the voltage required this is especially important on new installations.

Check for any foreign objects, loose nuts, bolts, and electrical connectors. Clear paper, leaves, building materials, etc., that could be sucked into the generator. (Generators are air-cooled. Air enters the lower portion of the conduit box.) Check the air gap for clearance or obstructions (main generator and exciter).

If possible, rotate the generator rotor by hand to be sure it turns freely.

If serious problems can be identified before attempting to operate the machine, additional damage can be avoided.

CONSTANT EXCITATION (12V BATTERY) TEST

THEORY: The generator output voltage is dependent on generator speed, generator design, load, and exciter input current. If the generator speed and exciter input are known, the output voltage at no load can be measured and compared to the design value. Problems can be isolated to either the generator or regulator system by using this test.

TEST PROCEDURE:

1. Shut the generator set down.

2. Connect a voltmeter to the generator output.

3. Disconnect the Fl and F2 leads at the regulator.

4. Connect a 12-volt battery capable of supplying 1 amp to the Fl and F2 leads. Fl is plus **(+),** F2 is minus (—).

CAUTION: Beware of arcing when connecting leads. Stay clear of battery vents. Escaping hydrogen gas can explode. If hazardous conditions exist - use a suitable switch to connect or disconnect the battery.

5. With no load on the generator, (main breakers open) run generator at rated speed.

6. Measure the generator output voltage.

7. Shut generator down.

8. Disconnect battery (see Caution - Step 3).

9. Compare voltage reading with value shown in section 12.

Conclusion: If voltage readings are normal, the main generator and exciter are operating properly. Troubleshooting should continue with the regulator. If readings are not normal the problem is in the generator. Continue testing diodes, surge suppressor, windings.

MEASURING VOLTAGES

When testing the generator and regulator, the most frequent (and usually easiest) measurement will be a voltage. The generator will need to be running at rated speed and may have some of the protective guards and covers removed. BE CAREFUL. Keep yourself and your test leads out of the way. It is best to shut the unit down when connecting meters. When using alligator clips or push on terminals, be sure the leads re supported so vibration does not shake them loose when running the generator set.

See figure 8-1 for measurement points and expected meter range settings.
When in doubt, start with a higher range and work down.
Consult meter instruction manual to verify its operation and limitations.

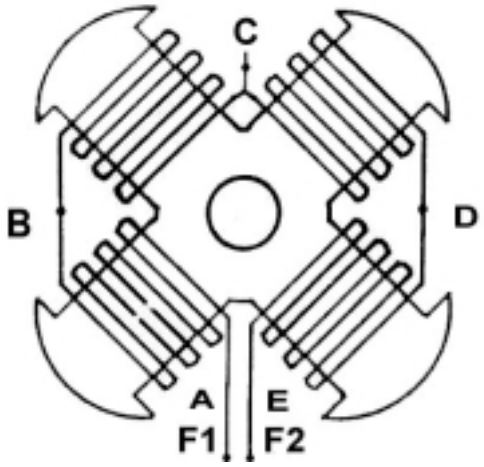

Figure 8-1

TYPICAL VOLTAGE MEASUREMENTS

Voltage Measurement	Test Point	Meter/Range Selection Requirement
Generator Output Voltage	Output "T" leads or bus bars, also main circuit breaker "line" side.	System voltage - volts AC See generator nameplate and connection diagram.
Regulator Output (Exciter Stator Input)	Fl and F2 terminals at the regulator.	200 volts D.C. range. Fl is plus (+), F2 if minus (—
Regulator Sensing	El, E2, E3 terminals at the Voltage the regulator.	Usually the same as the system voltage (generator output volts). However, in some cases, sensing taken from winding center taps or instrument potential transformers. Maximum 600 volts AC **Example:** Center tap of 480-volt system would give 240 volts El, E2, or E3. **Example:** A 4160-volt system must use a transformer to step voltage down below 600 volts. See the connection diagram supplied with generator set.
Regulator Input Volts (PMG Output Volts)	"PMG" leads at the regulator or capacitor.	200-240 VAC 300 Hz @ 1800 rpm 180-220 VAC 250 Hz @ 1500 rpm

CURRENT (AMP) MEASUREMENTS

Current measurement (AC) can be easily taken with a clamp on type meter.
NOTE: Most clamp type ammeters will not measure D.C.

When measuring generator output current, be sure the clamp is around all cables for each phase. If the physical size of the conductors or the capacity of the meters will not permit all cables to be measured at once, Each one can be measured individually. Add the individual readings together to get the total. Compare readings to the generator nameplate (nameplate ratings are always given per phase).

Amperage should never exceed the nameplate rating when running the intended load. (Amperage may go above nameplate momentarily when starting large motors.) When measuring exciter field amps (Fl and F2 leads) a D.C. meter is required. The maximum field current under full regulator forcing is 6.5 amps D.C.

MEASURING RESISTANCE

The generator windings can be measured and compared to the values shown in the service specifications.

Main Stator

The main stator winding resistance is very low. A meter capable of readings in the milliohm range would be required. However, a standard V.O.M. can be used to check for continuity, shorts, or grounds.

Example: With leads disconnected, a measurement from T1 to T4 should be very low (continuity most V.O.M's). Measured from T1 orT4 to any other lead should be infinite. Measure from the 'T' lead the generator frame to check for grounds (reading should be infinite).

Normal full load reading is approximately 3 amps.

The exciter stator resistance is measured by disconnecting the Fl and F2 leads at the regulator. Measure the resistance between the leads (this value is 22-24 ohms on standard generators). Measure from the leads to the frame to check for grounds.

Note markings and disconnect the main rotor leads (Fl leads and F2 leads) from the rectifier assembly. Measure the resistance of the main rotor winding. Compare reading to value shown in service specification section 12. Measure from the leads to the exciter-mounting bolt to check for grounds.

Exciter Rotor

Disconnect the exciter rotor leads at the diodes (leave leads disconnected if proceeding to check diodes). Measure resistance between phases. Compare value to service specification section 12. Measure from the leads to the exciter-mounting bolt to check for grounds.

TESTING DIODES (RECTIFIERS)

Diodes perform the function of an "electrical check valve". They conduct in one direction only and are used to "rectify" ac current into dc current. To test, measure the resistance first in one direction and then reverse the leads and test in the other direction. The reading should be high in the reverse direction and low in the forward direction. A shorted diode will read low in both directions. An open diode will read high in both directions.

NOTES:
1. Two different polarities of diodes are used. The only difference is in the way the device is mechanically placed in the case. When changing diode, be sure the correct polarity is used.
Refer to section 6 figure 6-34.

2. Some meters do not have enough voltage output from their internal batteries to turn the diode on (about 0.6 volts is required), and the voltage can change with different

range settings. Consult the instruction manual for your meter.
3. Polarities supplied by the meters internal battery may or may not correspond to the (+) (—) markings on the meter.

INSULATION RESISTANCE - *GENERAL*

Insulation resistance is a measurement of the integrity of the insulating materials that separate the electrical windings from the generators steel core. This resistance can degrade over time or due to contaminants (dust, dirt, oil, grease, and especially moisture). Most winding failures are due to a breakdown in the insulation system. In many cases, low insulation resistance is caused by moisture collected when the generator is shut down. The problem can be corrected simply by drying out the windings. Section 5.

Normally the resistance of the insulation system is on the order of millions of ohms. It is measured with a device called a “megger” which is a megohm meter (Meg is for million) and a power supply. The power supply voltage varies, but the most common is 500 volts. A megger voltage over 500 is not recommended except for measuring medium voltage (2400/4160) stators only.

CAUTION: First disconnect any electronic components, regulators, diodes, surge protectors, protective relays, etc., will be destroyed if subjected to the high megger voltages.

To measure insulation resistance, connect the red or positive megger lead to the leads for the winding to be tested, connect the back or negative megger lead to the generator frame. Be sure the leads of the part being tested are not touching any metal parts of the generator. (If the neutral is grounded, it must be disconnected.) Take megger reading (refer to the manual for the megger).

INSULATION RESISTANCE - MAIN STATOR

CAUTION: Be sure the regulator, and any other electronic components, metering, protective relays, etc., are disconnected before meggering. High megger voltages will destroy these parts. All stator leads must be isolated from ground and connected together (on most systems with grounded neutrals - the neutral can be isolated from ground and used as a test point). Connect the positive megger lead to the main stator leads. Connect the negative megger lead to the generator grounding stud. Take the megohm reading (refer to instructions for the megger).

GENERATOR TESTING

The minimum acceptable value can be calculated using the following formula.
Minimum Insulation Resistance = Gen. Voltage + 1 (Megohms) / 1000
Example:
For a 480 volt generator
480 + 1 = 1.48 Megohms
If the reading is below the recommended value, the winding must be dried out or repaired.

INSULATION RESISTANCE - MAIN ROTOR

Disconnect the main rotor leads from the diode bridge on the exciter rotor. Connect the leads together with the positive megger lead. Connect the negative megger lead to a good ground on the rotor assembly such as the exciter mounting bolt. Take the megohm

reading (refer to instructions for the megger).
The minimum acceptable value is 1.5 megohms.

If the reading is low, the winding must be dried out or repaired.

INSULATION RESISTANCE - EXCITER STATOR

Disconnect the exciter leads Fl and F2 from the regulator. Never subject the regulator to a megger. Connect Fl and F2 together with the positive megger lead. Connect the negative megger lead to the ground stud. Take the megohm reading (refer to instructions for the megger).

The minimum value is 1.5 megohms.

If the reading is low, the winding must be dried out or repaired.

INSULATION RESISTANCE - EXCITER ROTOR

Disconnect the exciter rotor windings (6 leads from the diodes). Connect all leads together with the positive megger lead. Connect he negative megger lead to a good ground on the rotor assembly such as the mounting bolt. Take the megohm reading (refer to the instructions for the megger).

The minimum acceptable value is 1.5 megohms.

If the reading is low, the winding must be dried out or repaired.

MAIN ROTOR FIELD AC IMPEDANCE TEST

THEORY: The main rotor resistance can be measured with a very accurate meter that is able to measure low (1 ohm) resistance but it is difficult to determine if there are turn to turn shorts in the field pole windings. One shorted turn would only change a resistance reading on the order of one half of one percent.

The ac impedance test measures the impedance (inductance and resistance) of the field pole coils. Shorted turns in the field pole windings change the coil inductance to a much greater degree than the resistance.

PROCEDURE:

Step 1: The rotor must be supported on a non-magnetic surface such as a wooden skid. Do not use a steel table that would create a magnetic “short circuit” between the poles.

Step 2: Apply 120 volts ac to disconnected main rotor leads Fl and F2.

Step 3: Measure and record voltages pole. Between points “A” and “C”, “C” and “D”, “D” and “E” across each “B”, “B” and (Figure 8-1).

Step 4: The voltage readings should balance within one volt.

RESULTS: If the ac voltages are not balanced (30v ± lv ac with 120v ac input) across each pole, the winding has shorted turns and should be rewound.

Refer to Katolight for further information.

STANDARD TOOLS

The MagnaMAX generator is assembled with American standard SAE hardware. All fasteners should be properly torqued. (See section 12). Torque wrenches ranging from 25 in-lb. through 200 ft-lb. should be available.

Electrical test equipment should include a voltmeter or multimeter (VOM), clamp on ammeter, accurate frequency meter or tachometer, and a megohmmeter. See section Generator Testing for more information.

SPECIAL TOOLS

In addition to the standard tools mentioned above, the following special tools would facilitate removal and installation of large and/or special parts. These tools can be obtained from the Katolight parts department.

Exciter stator lifting fixture (Figure 10-1).

Figure 10-1

In cases where the exciter stator is to be serviced without removing the generator conduit box this fixture can be used with overhead rigging to remove and reinstall the exciter stator.

Exciter rotor puller bolt (Figure 10-2). The exciter rotor has a built in pulling system. With the use of this bolt, the rotor can be easily removed from the shaft without damage to the winding.

Figure 10-2

The PMG rotor is installed to the generator shaft with a snap ring.

The nominal shaft diameter is 2-3/4 inches and the ring must be spread approximately 3/4 inches for removal. To install the snap ring, use a piece of pipe with a 2-3/4 inch I.D. (Figure 10-4). Push the PMG rotor and snap ring onto the shaft until the ring snaps into the groove.

Figure 10-4

Rotor lifting fixture (Figure 10-5). The main generator rotor is heavy (approximately 1/2 the weight of the generator) and difficult to handle. The proper fixture should be used whenever removing or installing the main rotor into the main stator. Without proper care and equipment, the windings can be easily damaged.

Figure 10-5

MISCELLANEOUS

A selection of wiring devices such as electric connectors, tape, cable ties, crimping and stripping tools, etc., should also be a part of the generator service tool kit. The standard regulator uses flat 1/4 inch female insulated terminals for AWG #14 wire.

PREPARATION FOR SHIPMENT OR EXTENDED STORAGE

SHIPPING INSTRUCTIONS

Shipping and handling will be much easier if the generator is fastened to a suitable shipping skid that will allow handling by a forklift. The skid should extend beyond the generator in all directions. If the original skid is available it should be used. Katolight will supply shipping skid drawings upon request.

Overseas shipping may require special export crating. Check with your freight carrier.

When installed, single bearing generator rotors are supported on the drive end by the drive discs bolted to the engine flywheel. When the engine is removed, the rotor must be supported by an appropriate fixture to prevent main rotor, main stator or exciter damage (Figure 11-1). Before shipping any single bearing generator, the main rotor must be supported by the adapter using an appropriate fixture.

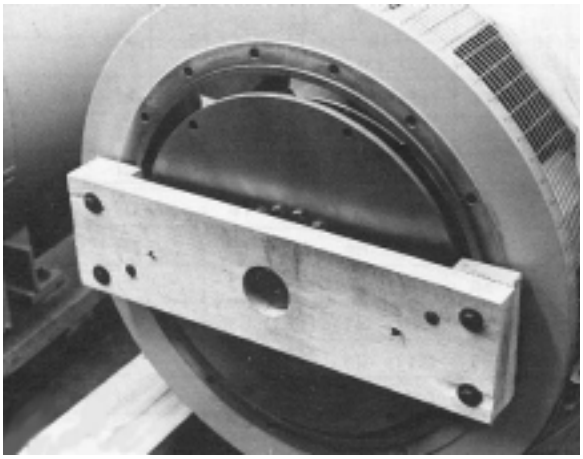

Figure 11-1

STORAGE INSTRUCTIONS

If the generator is placed in storage, the following precautions should be taken to protect it:

A. Equipment must be kept clean.

1. Store indoors.

2. Keep covered to eliminate airborne dust and dirt.

3. Cover openings for ventilation, conduit connections, etc. to prevent entry of rodents, snakes, birds, and insects, etc.

B. Equipment must be kept dry.

1. Store in a dry area indoor.

2. Temperature swings should be minimal to prevent condensation.

3. If stored in an unheated or damp building, space heaters will be required to prevent internal condensation.

4. Treat unpainted flanges, shafts, drive discs, and fittings with a rust inhibitor.

5. Check insulation resistance of all windings before starting the generator. If readings are low, the windings must be dried.

C. Keep bearings lubricated.

1. Every six months rotate shaft several turns to distribute grease in bearings.

2. If unit has been stored more than one year, add grease before start-up.

D. Review and follow instructions in Sections 3 and 4 before putting the gen-set into service.

CAUTION
DO NOT ATTEMPT TO TRANSPORT ANYGENERATOR WITHOUT PROPER ROTOR SUPPORT, EXTENSIVE EQUIPMENTDAMAGE CAN OCCUR.

NOTES: For table 12-1
All fasteners are SAE (American) standard.
All torque values are for plated hardware that is standard on the MagnaMAX.
If hardware is replaced with non-plated, refer to Table 12-2.
Always use quality hardware of the grade specified.
Main Rotor Coil Supports 570 and 740 frame only. Not used on 430 frames.

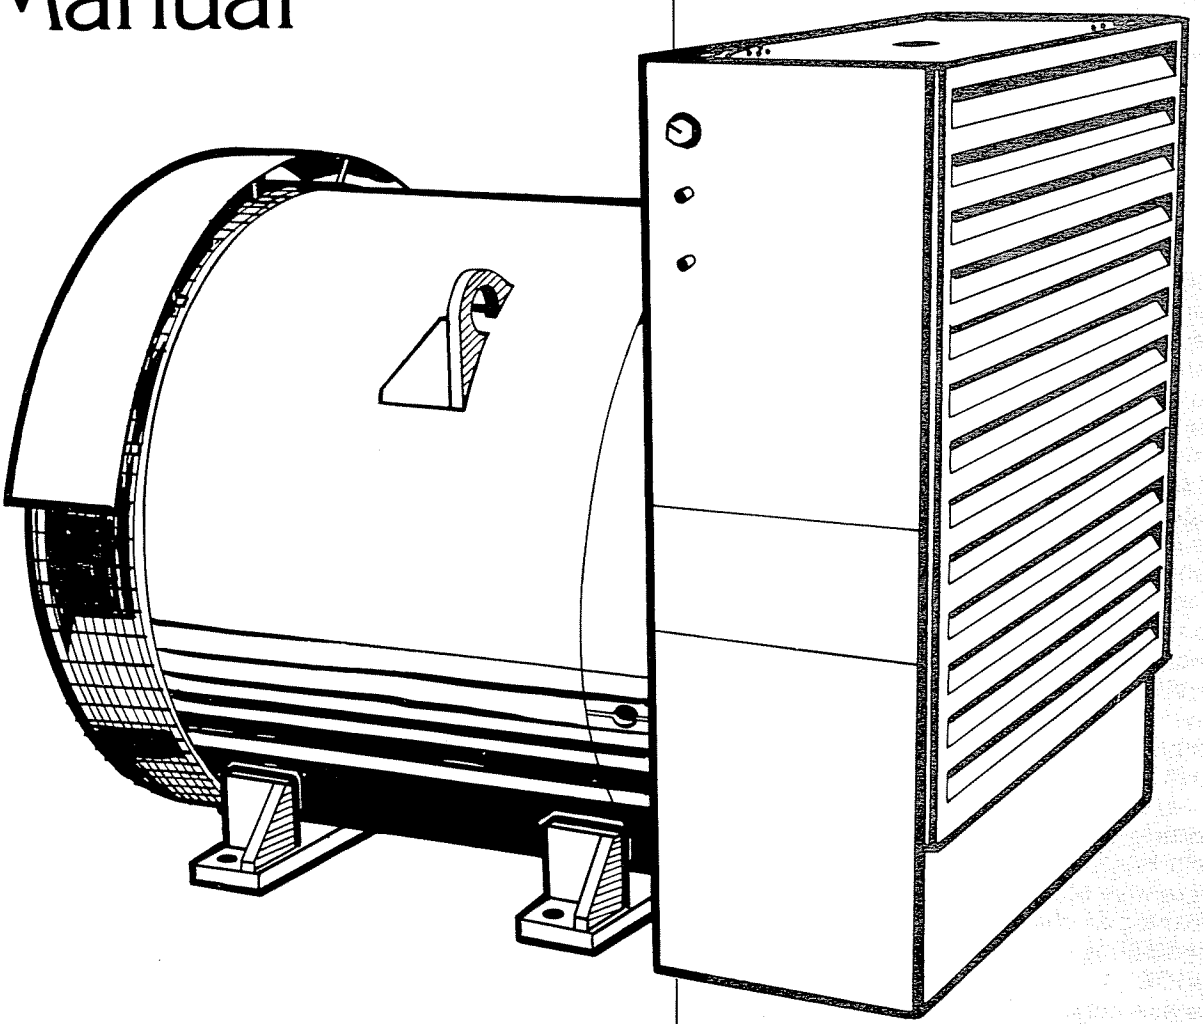
Magna One® Generator Installation, Operation and Maintenance Manual



MARATHON® ELECTRIC
WAUSAU, WISCONSIN 54401

FOREWORD

This service manual applies to Magna One brushless ac generators manufactured by Marathon Electric Manufacturing Corporation. It contains instructions for installation, operation, and maintenance of these generators. Also included is a Parts List Section, a Trouble Shooting Section, Shipping Instructions and a Sales and Service Listing.

WARNING

These instructions must be followed to insure safe and proper installation, operation and maintenance of the generator. They should be brought to the attention of all persons who install, operate or maintain this equipment.

Disconnect all power before servicing. Failure to follow all safety information can result in serious personal injury or death. Install and ground per local and national codes. Consult qualified personnel with any questions.

TORSIONAL VIBRATION

The factors which are most critical to torsional vibration are contained in the design of the engine. The engine-generator set manufacturer, his representative or buyer shall be responsible for the torsional analysis and approval of the engine-generator combination. Marathon Electric will submit to the above for approval rotor weight and WK^2 information, along with such other data as is deemed necessary when requested to do so.

Marathon Electric will proceed with the manufacture of generators prior to the receipt of torsional approval unless specifically requested in writing to delay production for receipt of such approval from the buyer. The buyer will be responsible for manufacturing charges incurred as a result of manufacturing prior to torsional approval.

Marathon Electric will not be responsible for the torsional vibrational characteristics of an installation when the engine vibrates on its base or steel bed and such vibration is transmitted to the supporting structure, or when the construction of the base is such that the engine-generator-mount natural frequency approaches that of the floor or sub-base resulting in magnification of vibration, or where the engine-generator combination has been found torsionally compatible, yet develops vibration due to a base of insufficient strength or inadequate sway-bracing.

GENERAL INFORMATION

GENERAL

A generator is a device which transforms mechanical energy into electrical energy. Magna One Generators are brushless, 4-pole machines producing 60 Hz power at 1800 rpm, or 50 Hz power at 1500 rpm (Hz = Hertz = cycles per second). All standard units are rated at 0.8 power factor.

Single bearing generators are supplied with an SAE adaptor and flexible drive discs on the drive end as standard. Alignment of the generator and engine is assured by the concentricity of the flywheel housing and the generator adaptor. Flexible drive discs are piloted in a rabbet in the flywheel itself, again assuring alignment. It may be necessary to shim the generator feet on the base for solid support. Two bearing units come standard with two brackets and a shaft extension for a drive coupling.

Ac generators require direct current flowing through the rotor winding to set up the magnetic flux which allows the unit to generate. A small ac exciter, which actually is a miniature replica of the main generator, provides this direct current. The exciter is mounted on the same shaft as the generator rotor. While the main generator field rotates and the armature is stationary, the exciter field is stationary and the armature rotates. The output from this exciter is fed into the rectifying elements mounted on a heat sink. This rectifier assembly is located on the end of the main shaft, opposite the drive end (see figure below).

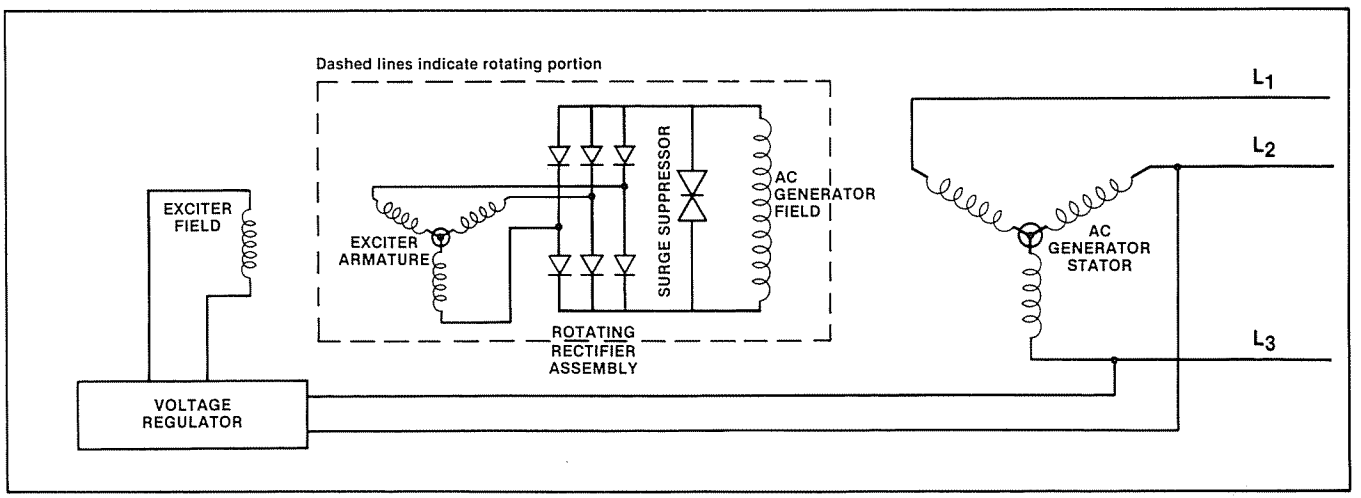
The ac exciter itself requires direct current for its excitation. This excitation is supplied by rectifying a portion of the output of the main generator by means of a static voltage regulator. The amount of current going into the field of the exciter will determine the output voltage of the exciter, and this in turn will control the output voltage of the main generator. Meters, controls, or other features needed to satisfy installation requirements are available as optional extras.

MECHANICAL CONSTRUCTION

Magna One brushless generators are designed and manufactured with the same engineering precision and craftsmanship that has, for years, gained Marathon Electric an outstanding reputation in this field. Precision machine parts, together with careful hand assembly, give the Magna One durability and reliability.

A solid, rolled steel frame, results in rigid support for the stator core and end brackets. The stator core is firmly anchored to the frame by the welding of bar steel core supports to the core and frame.

The end brackets and adaptors are made of cast iron for the ultimate rigidity required to support the heavy duty shielded bearings. A front bracket supports the stationary exciter field structure. For single bearing units, the frame is fitted with a rugged cast iron SAE adaptor, precision rabbeted to insure alignment with the prime mover. A nodular iron hub is keyed and heat shrunk to the shaft. This hub carries a number of flexible steel drive discs which have holes for fastening to the flywheel (for some adaptor-disc combinations a spacer is used between the hub and discs to maintain the proper distance between the discs and SAE adaptor face). This affords flexibility, in the axial direction, while in the radial direction it acts as a rigid coupling providing a uniform air gap.



GENERAL INFORMATION

For two bearing generators, a second bracket and standard shaft extension is substituted for the adaptor and flexible drive discs. The 360 and 440 Frames are available with long shaft extensions for belt drive applications while all frame sizes are suitable for coupled drive. When selecting a belt driven generator, refer to the chart on Page 6 for the drive details under which these units will operate successfully.

UNIROTOR™ CONSTRUCTION

A unique feature of the Magna One generator is that the amortisseur winding and coil supports are die cast as an integral part of the rotor. The 4 poles which carry the field windings are one piece laminations die cast with aluminum providing high mechanical integrity, and low vibration at operating speeds. This method has been time proven to be far superior to separate pole pieces which must be dovetailed to a spider or fastened by screws to the shaft.

The rotor pole assembly is heat shrunk and keyed to the shaft, forming a very rigid rotating element.

A thermo-setting bonding epoxy is applied between layers of the field winding and is applied to the finished rotor. The completed rotor is baked under a controlled cycle to ensure a solid, mechanically stable rotor. All rotors are dynamically balanced and then tested at a speed of 125% of the operating speed.

The ac exciter armature and the heat sink which carries the diodes are mounted on an assembly which is placed on the generator shaft outboard of the front generator bearing.

STATOR

The stator laminations are composed of thin, low-loss steel, notched on precision presses. The cores are reinforced by rugged steel stack rings and supporting bars which are welded around the core. Up to 600 volts, random-wound coils are placed in slots insulated with Class F materials. Once the properly insulated coils have been inserted in the stator core, the entire core is then given multiple dips and bakes in a thermo-setting varnish by a special process which ensures complete coverage. This premium insulation system utilizes all synthetic and non-hygroscopic materials making the standard windings fungus resistant and suitable for operation in high humidity and abrasive environments. Subsequently, the wound core is placed into and welded to the frame.

VENTILATION SYSTEM

Magna One generators employ an advanced flow-through ventilation system. The cast aluminum alloy ventilating fan draws air through louvers in the conduit box, over the main stator and exciter windings and exhausts it through ventilation screens in the adaptor. This exclusive design provides efficient cooling as air is distributed evenly throughout the generator, effectively reducing the recirculation of hot air. Since there is only one air intake, mounting of air filtration systems is easily accomplished.

ELECTRICAL CONNECTIONS

The large front end mounted conduit box is constructed of formed sheet steel with ample room inside for the voltage regulator, most circuit breakers and other options. A hole-saw or any suitable tool can be used to provide a hole for the conduit entrance. An approved connector must be used in conjunction with the conduit. The regulator can be moved from the left to the right side with relative ease if the entrance of the conduit is needed in this location.

IMPORTANT: To minimize the transmission of vibration, it is essential that flexible conduit be used for all electrical connections to the generator. Refer to the connection diagrams supplied with the generator and install all intercomponent and external wiring in accordance with the regulations of the national and local regulatory bodies. Be sure the generator frame is grounded to all the other components of this system with the ground wire complying with national and local codes. Terminal lugs① are provided on all low voltage (below 600 volts) generators except 682 frames where buss bars are used. Above 600 volts, terminal lugs① are used exclusively. Clean all contact surfaces to assure good electrical bonding with the generator lugs or buss bars. Use heavy duty terminal lugs or good quality clamps for making all connections. Tape all connections in accordance with national and local regulations.

①CSA certified terminal lugs are used.

RECEIVING YOUR MAGNA ONE GENERATOR

Upon receipt of the generator, it is recommended that it be carefully examined to determine if any shipping damage has occurred before accepting the shipment from the transportation company.

UNPACKING AND HANDLING

Read all instruction cards carefully. When lifting, attach an overhead crane to the lifting lugs on the generator frame. Apply lifting forces in a vertical direction, if possible.

WARNING

DO NOT LIFT COMPLETE GENERATOR SET BY MEANS OF LIFTING LUGS ON GENERATOR. PERSONAL INJURY OR EQUIPMENT DAMAGE MAY RESULT.

WARNING

DO NOT APPLY ANY FORCE TO GENERATOR FAN FOR LIFTING OR ROTATING GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

STORAGE

In the event that the generator is not to be installed on the prime mover immediately, it is recommended that it be stored in a clean, dry area which is not subject to rapid changes in temperature and humidity.

INSPECTION

It is recommended that the insulation resistance of the generator stator be checked with a megohmmeter prior to initial operation. In order to do this, all stator leads must be connected together and the insulation resistance measured from the lead terminals to the stator frame. Make certain the stator leads are not touching the frame. A megohm reading should be obtained that is equal to or greater than the following formula:

$$\text{Minimum Megohms} = \frac{\text{Rated Voltage}}{1000} + 1$$

An insulation resistance greater than the minimum indicates the insulation is in good condition. (NOTE: 1 megohm = 1,000,000 ohms.) A record should be kept of the resistance readings for comparison with future data. A drop in resistance values indicates wet, dirty or grounded insulation. In this case, clean and dry the winding using one of the listed methods on the following pages and check for grounds following the instructions in the "GENERATOR INSULATION TESTING" section.

CAUTION: READ THE "GENERATOR INSULATION TESTING" SECTION THOROUGHLY BEFORE USING A MEGGER ON THE ROTOR OR EXCITER FIELD. EXTENSIVE EQUIPMENT DAMAGE CAN RESULT FROM IMPROPER TESTING.

INSTALLATION

MOISTURE REMOVAL

Machines that have been idle for sometime in unheated and damp locations, may have "sweated" as a result of sudden changes in temperature or may have become wet by accident. These should be dried out thoroughly before being put into service. The following are recommended drying methods.

Oven

Place the machine in an oven and bake it at a temperature not to exceed 90 degrees C or 194 degrees F. The voltage regulator and any electronic component accessories must be removed from the generator when using this method.

Space Heaters

Enclose the generator with a covering and insert heating units (space heaters, lamps or coils of steam pipe) to raise the temperature. Leave a hole at the top of the enclosure to permit the escape of moisture.

Forced Air

A portable forced air heater can be used by directing heat to the end of the generator opposite the coupling and running the generator with no load and without excitation (this can be accomplished by removing the regulator fuses). Heat at point of entry should not exceed 66 degrees C (150 degrees F) at the bearing hub.

"Short Circuit" Method

The Generator can be dried out quickly and thoroughly by using this method. NOTE: Be sure that all of the following steps are performed and all precautions taken as personal injury or serious damage to the generator could result.

1. Disconnect exciter leads F1 and F2 from the terminal block.
2. Connect a dc battery or other dc power source of approximately 20-35 volts (depending on the kW of your unit) to the exciter leads F1 and F2. An adjustable voltage source is desirable, however a voltage adjust rheostat (rated approximately 2 amps) in series with the dc power source will accomplish the same result.
3. Short circuit the generator lead wires to each other (L1 to L2 to L3).
4. Start the generator and measure the current through the leads with a clip-on ammeter.
5. Adjust the voltage source to produce approximately 80% of the rated ac nameplate current, but in no case exceed nameplate amps. If an adjustable source is not available and current is excessive, use a small dc source or a large resistor in series with the source.

   Running time will be determined by the amount of moisture present in the machine. Insulation resistance checks should be taken every one to four hours until a fairly constant value is obtained, equal to or greater than the following formula:

$$\text{Megohms} = \frac{\text{Rated Voltage}}{1000} + 1$$

6. After machine has achieved a constant resistance value, disconnect the dc power source and reconnect F1 from the exciter to F(+) on the terminal block, and F2 to F(-). Make sure that all leads are reconnected properly.

If it is necessary to dry out the generator, it is recommended that the unit be thoroughly tested using the "Generator Insulation Testing" procedures found on the next page.

GENERATOR INSULATION TESTING

The following tests can be used to check minimum insulation resistance. Minimum insulation resistance can be tested using a megohmmeter.

CAUTION: MEGOHMMETER MUST NEVER BE APPLIED TO VOLTAGE REGULATOR OR DIODES - EQUIPMENT DAMAGE WILL RESULT.

$$\text{Minimum insulation resistance in megohms} = \frac{\text{Machine Voltage}}{1000} + 1$$

Example: 480 volt line to line generator:

$$\text{Minimum Insulation Resistance} = \frac{480}{1000} + 1 = 1.48 \text{ Megohms}$$

MAIN STATOR (ARMATURE)

1. All stator leads must be connected together. Connect one megohmmeter lead to stator leads and the other megohmmeter lead to the generator frame. Make sure the other stator leads are not touching the frame.

   a. A reading lower than the calculated minimum indicates an unacceptably low generator insulation resistance.

   Clean, dry and/or repair stator, replace if necessary.

MAIN ROTOR (MAIN FIELD)

1. Disconnect the two generator main field leads which come out through the end of the rotor shaft. These wires connect to each of the two diode heat sinks.

   NOTE: Make sure neither of the two leads touch any other part.

2. Apply one megohmmeter lead to one generator field lead and the other megohmmeter lead to the aluminum standoff casting (behind insulation plate on exciter rotor).

   a. A reading of less than the calculated minimum indicates an unacceptably low main field insulation resistance.

   Clean, dry and/or repair generator rotor, replace if necessary.

EXCITER STATOR (FIELD)

1. Disconnect exciter field leads from F+ and F- on terminal strip next to opening inside regulator box.

   NOTE: Location and markings on wires.

2. Connect one megohmmeter lead to exciter field lead and the other to the exciter frame.

   a. A reading lower than the calculated minimum indicates an unacceptably low exciter field insulation resistance.

   Clean, dry and/or repair the exciter stator, replace if necessary.

EXCITER ROTOR (ARMATURE)

1. Remove diode leads from studs, being certain to note the proper location for reconnection.

2. Apply one megohmmeter lead to one of the exciter rotor leads and the other lead to the aluminum standoff casting (behind insulation plate on exciter rotor).

   a. A reading of less than the calculated minimum indicates an unacceptably low exciter rotor insulation resistance.

   Clean, dry and/or repair the exciter rotor, replace if necessary.

INSTALLATION

PREPARATION FOR USE
GENERATOR MOUNTING

PREPARATION FOR USE

Although the generator is carefully inspected and tested in operation before it leaves the factory, it is recommended that the unit be thoroughly inspected. The insulation on the wire should be inspected and all bolts should be checked for tightness.

Remove all shipping tapes, bags, blocks and skids which are used to prevent vibration and rotor movement during shipment. Dry, low-pressure compressed air of approximately 30 PSI (206 KPA) can be used to blow out the interior of the generator. In the case of two bearing machines, it is possible to turn the rotor by hand to make sure that it rotates smoothly without binding.

If the machine has been in storage for a year or longer, it is recommended that it be lubricated according to the lubrication instructions and chart found in the "Lubrication" section of this manual.

GENERATOR MOUNTING

Single bearing generators are provided with an SAE flywheel adaptor and flexible drive discs. Very close tolerances are maintained in the manufacture of the generator so that the alignment procedure is extremely simple. A coupling hub of nodular iron is shrunk on the shaft and special steel drive discs are bolted to the hub. Holes are provided in the periphery of the coupling disc which correspond to tapped holes in the flywheel. The outside diameter of the discs fits in a rabbet in the flywheel so that concentricity is assured in all cases.

CAUTION: GRADE 8 CAPSCREWS AND HEAVY SERIES LOCKWASHERS OR GRADE 8 PLACE-BOLTS AND HARDENED WASHERS ARE RECOMMENDED TO MOUNT THE DRIVE DISCS TO THE FLYWHEEL.

The SAE adaptor and the flywheel housing are designed to match each other with no further alignment necessary. Shims may be necessary under the feet of the generator to insure a solid mounting.

TWO BEARING GENERATOR MOUNTING

Two bearing generators are provided with a shaft extension and keyway. For direct-coupled units, the assembler furnishes a flexible coupling which is installed between the driver and the generator shaft.

IMPORTANT: Aligning the two machines as accurately as possible will reduce vibration and insure minimum coupling wear. It may be necessary to shim the generator feet for proper support.

BELT DRIVE

360 and 440 frame, two bearing generators can be belt driven. Please refer to Marathon Electric for application assistance involving belt driven installations. Sheave diameters should be chosen according to the table below.

Magna One Sheave Application for Two Bearing Units①

Model	Min. Sheave Dia. in Inches @ 10,000 Hr. B-10 Life③		Min. Sheave Dia. in Inches @ 20,000 Hr. B-10 Life③		Max. Sheave Width Inches
	60 Hz	50 Hz	60 Hz	50 Hz	
360FDR8500	7.1	6.0	9.5	8.1	5.88
360FDR8504	7.9	6.7	10.4	8.7	5.88
362FDR8508	8.7	7.7	11.8	10.3	5.88
362FDR8512	12.2	10.0	16.8②	13.7	5.88
440FDR8016	10.2	8.5	13.7②	11.3	8.50
440FDR8020	12.7	11.2	17.2②	15.1	8.50
440FDR8024	14.4	12.4	19.6②	16.9②	8.50

①Assumptions:
A. Belting factor is 1.3.
B. The drive and the driven sheaves are the same diameter.
C. The sheave load is located at the center of the shaft extension.
D. Based upon continuous kW ratings.

② These sheave diameters exceed the maximum recommended belt speed of 6000 ft/min.
③ B-10 Life means 90% of the bearings will last this long or longer.

GENERATOR LEAD CONNECTIONS

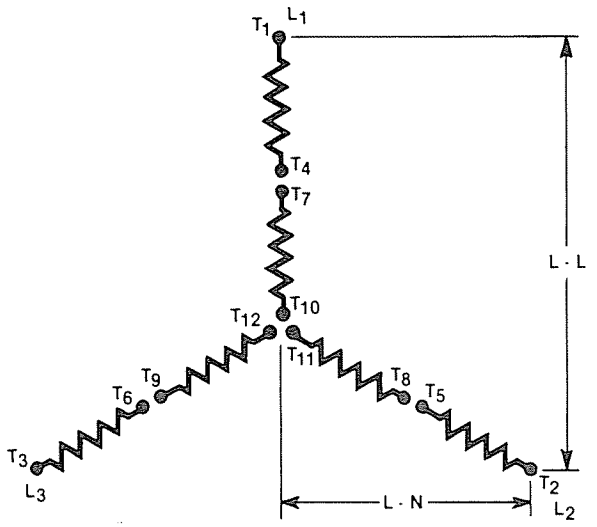
The electrical connections in the conduit box should be made in accordance with the appropriate "connection diagram." Use the diagram appropriate for the number of leads and voltage range required.

The final voltage setting is established within the selected range by an adjustment of the voltage regulator.

The use of flexible conduit is required to minimize the effect of the engine vibrations.

CAUTION: SOME GENERATORS HAVE MULTIPLE, IDENTICALLY MARKED, CABLES FOR EACH LEAD. CONNECT ALL IDENTICALLY MARKED CABLES TOGETHER WHEN MAKING CONNECTION TO LOAD.

12 LEAD HI WYE



Twelve lead generators are dual voltage generators with six coils which don't have the connection of the three inner coils. There are 12 or 24 cables coming out of the generator.

PARALLELING OPERATIONS

Magna One generators come standard with amortisseur windings die cast as an integral part of the rotor. This exclusive Unirotor construction makes all Magna One generators suitable for paralleling operations when the proper control equipment is added.Paralleling with other generator sets and/or with the utility power grid offers a number of advantages. Multiple unit installations increase power capacity; they can be added or removed from the load depending on the load required; they can be better maintained and repaired (since single source breakdown would mean total loss of power) and they often provide more reliable, efficient and economical operation.

Successful parallel operation means that the generators deliver power to the external system without delivering power to each other, or accepting power from the load buss or power grid. Additional equipment is necessary to insure safe and successful operation.

PRIME MOVER

The prime mover provides the speed and torque which will be necessary to keep the machines in synchronized operation. The speed will directly control the watt or kW load and frequency of the unit. The prime mover speed is controlled by a governor. The governor must have special paralleling and droop provisions to permit parallel operation with other machines.

VOLTAGE REGULATOR

The voltage regulator controls the generator output voltage and the reactive power supplied by the generator. When two or more ac generators operate in parallel, the voltage regulator must have paralleling provisions (either internally or external to the regulator) to permit it to control the reactive or VAR load while it is in parallel operation. A separate paralleling current transformer is required to sense the reactive current and signal the voltage regulator. This additional paralleling circuitry is absolutely necessary to control the reactive current flowing between the generator sets.

SWITCHGEAR

There are additional relays and breaker controls which are necessary to insure safe, trouble free operation of paralleled units. Reverse power relays monitor the direction of power flow to insure that the generator is delivering power, not accepting it. These power relays control breakers, which are a means of connecting and disconnecting the generator from the load. The total system can include over-voltage, over-current protection, under frequency protection, power factor correction provision and various associated control equipment from manual switchgear to micro-processors. The amount of control gear and level of sophistication will be determined by the needs and requirements of the particular application.

PARALLELING BASICS

The following points are basic criteria which must be met before two units can be paralleled. THIS IS NOT MEANT TO BE SPECIFIC INSTRUCTIONS FOR PARALLELING OPERATION.

1. Additional paralleling circuitry
   - A. Voltage regulator - paralleling provisions
   - B. Paralleling current transformers(s)
   - C. Paralleling provisions on governor controls
   - D. Switchgear
2. The voltage and frequency must be the same for all sets with voltages in phase.
3. The voltage regulation characteristics of the individual generators should be similar.
4. The generators must have the same phase rotation.
5. The driving engines should have the same speed regulation characteristics and the governors should be adjusted to give the same speed regulation.

Before operating generator sets in parallel, each set should be checked by starting, operating and adjusting the sets as individual units before attempting paralleling.

INSTALLATION

PARALLELING OPERATIONS
THYRISTOR OR SILICON CONTROLLED RECTIFIER LOADING

REACTIVE LOAD CONTROL

When two identical generators are operating together in parallel and an unbalance occurs in field excitation, circulating currents begin to flow between the generators. This current will appear as a lagging power factor or inductive load to the highly excited generator, and as a leading power factor or capacitive load to the generator with the lower field current. This is known as the reactive circulating current and there are two methods of controlling it in parallel operation:

1. Reactive droop compensation. (Formerly known as parallel droop compensation.)

   The bus voltage droops, or decreases, as the reactive lagging power factor load is increased.

2. Reactive differential compensation. (Formerly known as cross current compensation.)

   The reactive differential compensation circuit allows parallel generators to share reactive loads with no decrease or droop in generator voltage. The RDC circuit must meet the following criteria:

   A. All paralleling current transformers for all the generators being paralleled must be included in the secondary interconnection loop.

   B. When different size generators are paralleled, all paralleling current transformers must have the same or proportional ratios that give approximately the same secondary current.

   C. Voltage regulator paralleling circuitry must be the same.

   D. Current transformer secondaries and the generator lines must be isolated electrically.

      Because of the above criteria, reactive differential compensation cannot be used when paralleling with the utility power grid. There is no limit, however, in the number of generators that can be included in this type of circuit.

   E. It is also desirable to have an auxiliary contact on the main generator breaker to short the parallel CT secondary when that breaker is open (not connected to the load buss).

PARALLELING CIRCUITRY

Because of the number of variables involved in paralleling generator sets, every installation will have its own circuitry and methods or procedures of bringing paralleled units on line. There are numerous ways of connecting paralleled units and an almost unlimited variety of applications and associated equipment.

When parallel operation is desired, it is important that the control manufacturer, the generator manufacturer and the systems engineer work together to insure the proper selection of all components. Please refer to Marathon Electric for application assistance.

THYRISTOR OR SILICON CONTROLLED RECTIFIER LOADING

Solid state electronic control devices which utitize thyristors or SCR firing circuits (such as variable frequency induction motor controls, precision motor speed controls, no-break powered battery chargers, etc.) can introduce high frequency harmonics which adversely affect or distort the normal waveform of the generator. This creates additional heat in the generator stator and rotor, and can cause overheating. These devices can and do present problems to non-utility power generating equipment or any limited power buss system. The problems which can occur are not limited to the generator itself, but can effect the solid state control devices, the equipment it controls, other associated loads, monitoring devices or a number of combinations over the entire system.

Magna One generators can supply some thyristor and SCR loads when properly applied. For a single thyristor (SCR) load, the maximum KVA load on the generator should be limited to about 60% of the generator rating. Where thyristor (SCR) loading is less than 30% of the total loading, derating of the generator is not normally required. It is important that the control manufacturer, the generator manufacturer and the systems engineer work together to insure the proper selection of all components. Please refer to Marathon Electric for application assistance.

OPERATION

PRE-START INSPECTION

Before operating the generator for the first time, the following checks are recommended.

1. Check all wiring against the proper connection diagrams and make sure all connections are properly insulated.
2. Inspect for any remaining packing materials and remove loose clothes and all tools.
3. Check that all covers and guards are installed and tight.

IDLING

Permanent equipment damage can be caused by idling the engine between 650 and 1400 generator rpm. If engine adjustments require idling at these speeds, the REGULATOR FUSES MUST BE REMOVED before engine start-up and adjustment.

WARNING

RESIDUAL VOLTAGE IS PRESENT AT THE GENERATOR LEADS AND AT THE REGULATOR PANEL CONNECTIONS, EVEN WITH THE REGULATOR FUSES REMOVED. CAUTION MUST BE OBSERVED OR SERIOUS PERSONAL INJURY OR DEATH CAN RESULT. CONSULT QUALIFIED PERSONNEL WITH ANY QUESTIONS.

If generator is supplied with the optional regulator power "off-on" switch, simply turn the switch to the "off" position; or if supplied with the optional underfrequency module, the regulator is protected. WHEN IN DOUBT, REMOVE THE FUSES. After engine adjustment, the regulator fuses should be replaced. The engine should be brought through the 650-1400 rpm range in less than 45 seconds.

VOLTAGE ADJUSTMENTS

A means for adjusting the voltage is incorporated in the regulator. For details refer to the Voltage Regulator Manual applicable to this unit.

STARTING-UP THE GENERATOR

The following procedure should be followed for starting-up the generator set:

1. The generator output must be disconnected from the load. Be certain that the main circuit breaker is open.
2. Start the prime mover and adjust it for the proper speed. If unit is not frequency protected, remove the fuses.
3. If fuses have been removed, replace the fuses and adjust the voltage to the required value by means of the voltage adjust rheostat.
4. Close the main circuit breaker and apply the load.
5. Adjust engine speed at full load to 1800 rpm for 60 hertz, 1500 rpm for 50 hertz.
6. Before stopping the engine, remove the load by tripping the main circuit breaker.

FIELD FLASHING

The generator relies on residual voltage to start the generator action which in turn produces the rated voltage. If the generator fails to produce a voltage after it has come up to rated speed, it may be necessary to flash the field. This procedure must be done while the generator is at a standstill. See the Field Flashing Procedure for further information.

FIELD FLASHING PROCEDURE

With the generator set shut down, apply a 12 volt dc flashing source (battery) across terminals F+ and F- on the voltage regulator. The positive terminal of the battery must be connected to F+ and the negative terminal to F-. CAUTION: If these leads are reversed, the voltage regulator will be destroyed. A diode in the voltage regulator allows the flashing source to be removed from the field without the danger of inductive arcing. This action remagnetizes the exciter field and allows build-up when the system is restarted.

Katolight Service - Master Repair Manual - Page 897

OPERATION

PREVENTATIVE MAINTENANCE
CLEANING METHODS

PREVENTATIVE MAINTENANCE

Dirt and heat are common enemies of a generator. Keeping the generator clean, preventing overloads, and proper alignment of the generator and its prime mover will result in efficient operation.

Accumulations of dust and dirt not only contribute to insulation breakdown, but they can also increase temperature by restricting ventilation and by blocking the dissipation of heat from the winding and frame surfaces. Some machines are exposed to accumulations of materials such as talc, lint, or cement dust, which may obstruct the ventilation. The most harmful types of foreign materials include carbon black, metallic dust and chips, and similar substances which not only impede the ventilation, but also form a conductive film over the insulation, increasing the possibility of insulation failure. Machines operating in dirty places should be disassembled and cleaned periodically.

Dirt and dust will conduct electricity between points of different electrical potential. The regulator must be kept free of excessive amounts of dust and dirt. Low pressure, moisture-free compressed air may be used to blow out any dust and dirt.

CLEANING METHODS

When electrical components get dirty, the insulation must be cleaned. There are a number of acceptable methods for cleaning the generator, each of which will necessitate disassembly of the unit. The method of cleaning will be determined by the kind of dirt, and when the unit must be returned to service. Drying after cleaning is necessary.

Whenever the generator is disassembled, the windings should be given a thorough inspection and the insulation cleaned, if necessary. The inspection should cover the condition of the windings and insulation, and the effectiveness of the supporting ties as evidenced by the rigidity of the coil end turns.

SOLVENTS

It is recommended that only petroleum distillates be used for cleaning electrical components.

A solvent is usually required to remove accumulated soil containing oil or grease. A wet rag with solvent is suitable for wiping.

Dry components thoroughly with moisture-free, low pressure compressed air.

CAUTION: CARE MUST BE TAKEN NOT TO GET SOLVENT ON INSULATING VARNISHES OR DETERIORATION OF VARNISH WILL OCCUR.

Petroleum solvents of the safety type should be used. The flash point of these solvents should be greater than 100° F (38° C).

WARNING

ADEQUATE VENTILATION MUST BE AVAILABLE TO AVOID FIRE, EXPLOSION AND HEALTH HAZARDS WHERE SOLVENTS ARE USED. AVOID BREATHING SOLVENT VAPORS. RUBBER GLOVES OR OTHER SUITABLE PROTECTION FOR THE HANDS SHOULD BE USED.

CLOTH AND COMPRESSED AIR

Cleaning with a dry cloth may be satisfactory when components are small, the surfaces are accessible and only dry dirt is to be removed.

Blowing dirt out with compressed air is usually effective particularly when the dirt has collected in places which cannot be reached with a cloth. Use clean dry air at 30 PSI (206 KPA).

BRUSHING AND VACUUM CLEANING

Dry dust and dirt may be removed by brushing with bristle brushes followed by vacuum cleaning. Do not use wire brushes. Vacuum cleaning is an effective and desirable method of removing dry and loose dirt.

SHELL BLASTING

Air blasting with ground nut shells may be satisfactory for removal of hand dirt deposits from insulation. Use mild abrasives such as 12-20 mesh ground walnut shells.

DRYING ELECTRICAL INSULATION

Electrical components, after cleaning, storing or shipping must be dried before placing in operation if tests indicate that the insulation resistance is below a safe value. See approved drying procedures in the "Installation Section" of the manual.

DRYING ELECTRICAL INSULATION

Electrical components, after cleaning, storing or shipping must be dried before placing in operation if tests indicate that the insulation resistance is below a safe value. See approved drying procedures in the "Installation Section" of the manual.

AIR INTAKE AND EXHAUST

Check the area around the air intake and exhaust openings to be sure they are clean and unobstructed. Remove all foreign material and clean all screens.

ELECTRICAL CONNECTIONS AND WINDINGS

Inspect for loose or contaminated connections. Check wires for cracked or frayed insulation. Tighten connections and replace defective or oil soaked insulation.

If inspection shows that varnish coatings on the windings have deteriorated, they should be recoated with insulating varnish. Please refer to Marathon Electric for insulation system requirements.

LUBRICATION

All generators are lubricated before leaving the factory and are ready for operation. As a general rule, bearings should be relubricated annually or at the indicated intervals in table 1, whichever occurs first. Unusually severe operating conditions, such as high ambient or dusty environments, require more frequent lubrication (every six months or one half the table intervals, whichever occurs first). 360 Frame generators are premanently lubricated, and therefore regreasing is not necessary.

Use Cheveron SRI #2 or equivalent anti-friction type, high quality, grease with a lubrication temperature range of lowest ambient temperature expected to +260°F.

During an overhaul, the grease reservoir should be thoroughly cleaned and new grease added. The reservoir should be 1/3 to 1/2 filled with new grease.

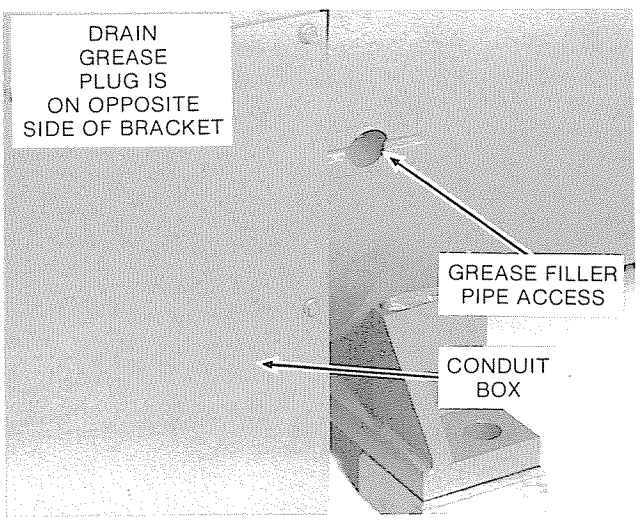
To add or renew grease, proceed as follows:

1. Stop unit.
2. Wipe clean the grease plugs and surrounding parts.
3. Remove filler and drain plugs (see figure to right).
4. Insert 1/8" N.P.T. grease fitting or appropriate fitting in filler pipe.
5. Free drain hole of any hard grease, using a piece of wire if necessary.
6. Using a low pressure grease gun, add grease according to the amounts in table 1.
7. Start unit with drain plug removed - filler pipe may be open or closed. Allow unit to run 15 minutes to allow excess grease to drain.
8. Stop unit, wipe off any drained grease, and replace filler and drain plugs.

CAUTION: USE ONLY CLEAN GREASE FROM CLEAN, CLOSED CONTAINERS AND KEEP IT FROM BEING CONTAMINATED WHILE REGREASING.

The amount of grease added is very important! Only enough grease should be added to replace the grease used by the bearing.

CAUTION: TOO MUCH GREASE CAN BE AS HARMFUL AS INSUFFICIENT GREASE - USE THE PROPER AMOUNT.



OPERATION

LUBRICATION

TABLE 1: RELUBRICATION AMOUNTS AND INTERVALS

	FRAME SIZE	BEARING SIZE	AMOUNT OF GREASE			INTERVALS①	
			OUNCES	CUBIC INCHES	TEASPOONS	60 HZ	50 HZ
SINGLE BEARING UNITS	440	312	1.0	1.8	5.8	7600	8800
	500, 502	314	1.2	2.1	7.0	6500	8400
	680, 682, 683	320	2.1	3.7	12.2	3800	5300
DOUBLE BEARING UNITS (SHAFT END BEARING ONLY)	440	318	1.7	3.0	9.9	4600	6200
	500, 502	318	1.7	3.0	9.9	4600	6200
	680, 682, 683	322	2.4	4.2	14.0	3000	4500

①HOURS OF RUNNING TIME

REMOVAL FROM PRIME MOVER

WARNING

DISCONNECT ALL POWER BEFORE SERVICING. FAILURE TO FOLLOW ALL SAFETY INSTRUCTIONS CAN RESULT IN SERIOUS PERSONAL INJURY OR DEATH.

1. Remove louvered conduit box cover. (See Figure 1).

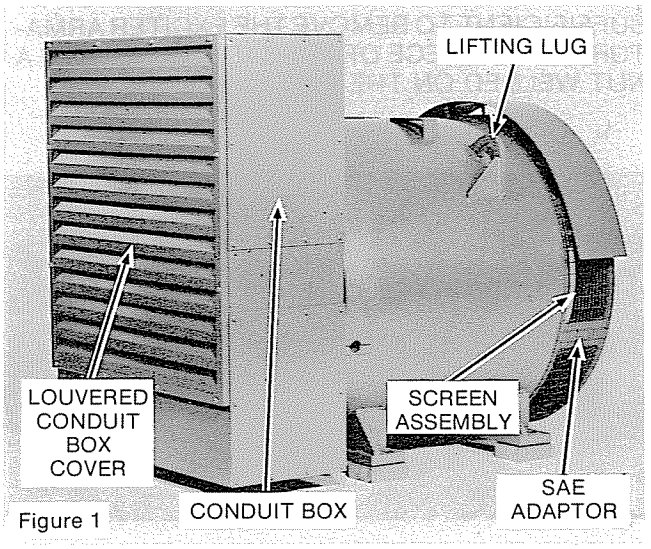


Figure 1

2. Disconnect all electrical load leads from the generator leads (or buss bars) inside the conduit box.
3. Remove all conduit or ducting from the conduit box.
4. Attach a suitable hoist to the generator lifting lugs.
5. a. For two-bearing generators, disconnect the coupling or sheave and belts between the generator and prime mover. (Follow the coupling manufacturer's instructions for disconnection.)

   b. For single bearing generators, remove the bolts mounting the screen assembly to the SAE adaptor and remove the screen. (See Figure 2.) (NOTE: Do not remove the dripcover from the screen assembly if so equipped.) Remove the capscrews attaching the drive discs to the flywheel and remove the capscrews attaching the SAE adaptor to the flywheel housing.

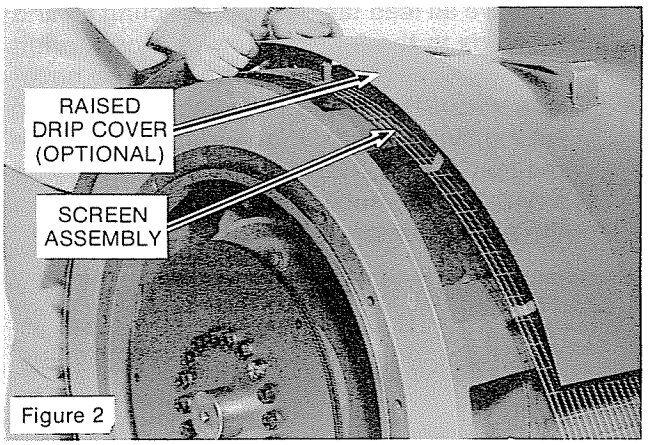

Figure 2

WARNING

DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

6. Remove the mounting bolts which secure the generator to the base.
7. Raise the generator slightly and move the generator away from the prime mover.
8. On single bearing generators, if generator is to be shipped, see Shipping Instructions Section for proper rotor support.

EXCITER REMOVAL

1. Remove regulator enclosure and disconnect F1 and F2 leads from the corresponding F+ and F− terminals on the terminal block on the regulator panel. (See Figure 3).

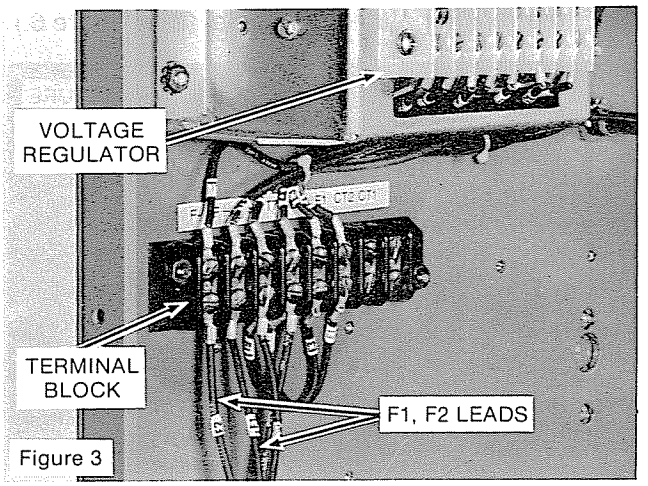

Figure 3

SERVICE

DISASSEMBLY

2. Remove all lead fasteners connecting F1 and F2 leads to the front end bracket or conduit box. Remove the four capscrews and belleville washers holding the exciter stator and lead shield in place. (See Figure 4.) Remove the lead shield. Mark the exciter stator "top front" for reference. (See Figure 5.) Remove the exciter stator.

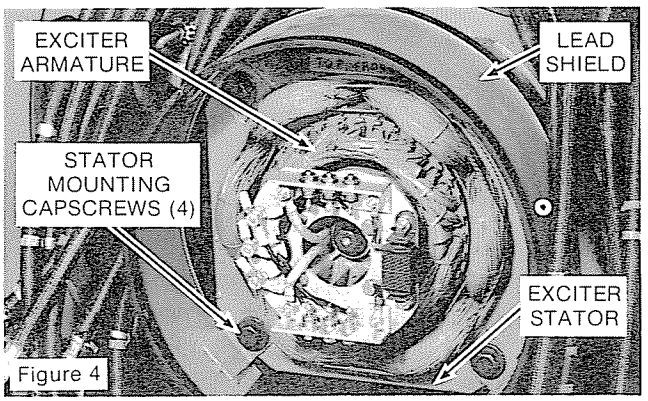

Figure 4

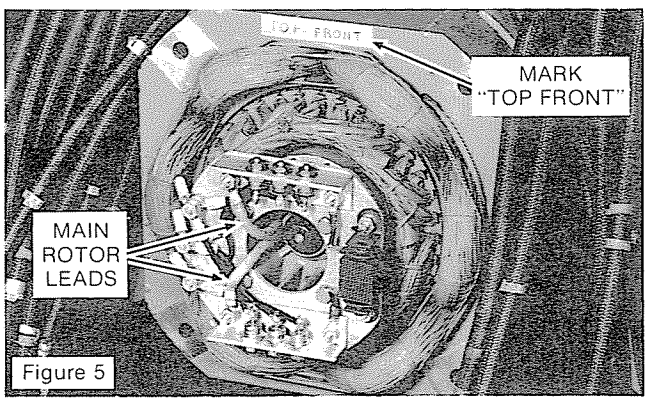

Figure 5

3. Disconnect both main rotor leads coming out of the aluminum standoff plate lead hole from the rectifier aluminum angle. (See Figure 6.)

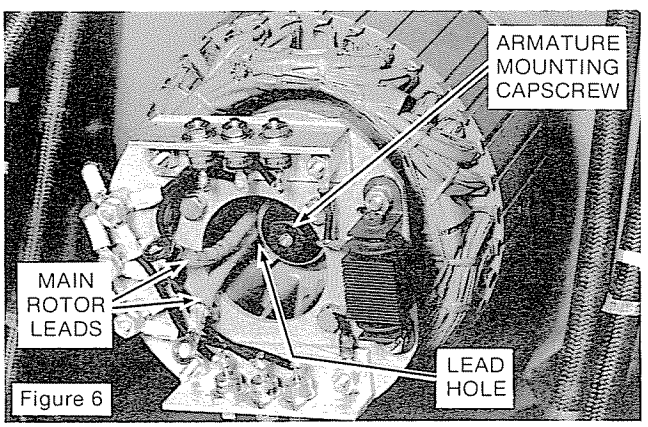

Figure 6

4. Remove the capscrew and belleville washer which holds the exciter (rotor) armature to the generator shaft. Use a six inch, 3/4 - 16NF capscrew threaded into the aluminum standoff plate to push against the end of the shaft. (See Figure 7.) Carefully feed the leads through the lead hole in the aluminum standoff plate as the armature is removed.

CAUTION: DO NOT TIGHTEN THE ARMATURE REMOVAL CAPSCREW BEYOND THE END OF THE THREADS. IF THE THREAD LENGTH IS NOT SUFFIFICIENT TO REMOVE THE EXCITER ARMATURE, USE A PIECE OF THREADED ROD WITH A NUT WELDED ON THE END.

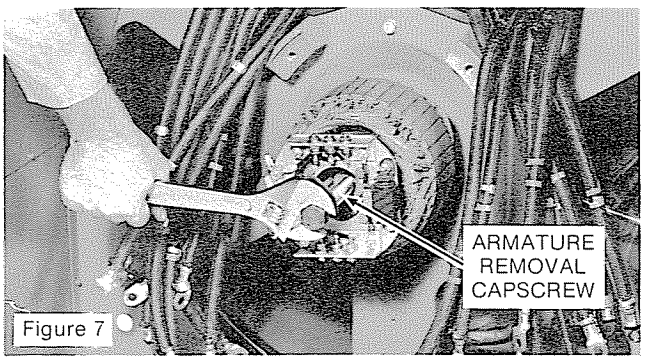

Figure 7

MAIN ROTOR REMOVAL

1. a. For two bearing generators, remove the two capscrews and lockwashers holding the bearing lock to the drive end bracket. On 680, 682 Frame generators, remove the two capscrews holding the bearing cap to the front end bracket. (See Figure 8.)

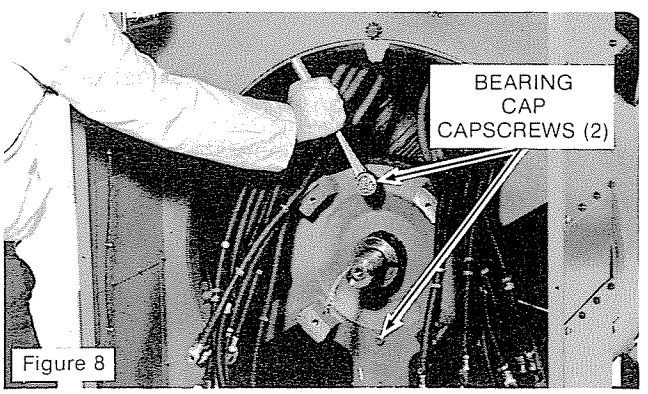

Figure 8

b. For single bearing 680, 682 Frame generators, remove the two capscrews holding the bearing cap to the front end bracket. (See Figure 8.)

2. If the screen assembly is still mounted, remove the bolts securing the screen assembly to the drive end bracket or the SAE adaptor and remove the screen assembly. (See Figure 9.) (NOTE: Do not remove the drip cover from the screen assembly if so equipped.)

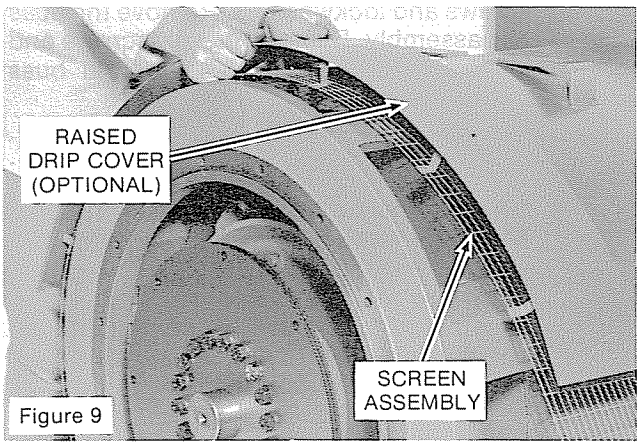

Figure 9

3. a. For two bearing generators, remove the drive coupling half or sheave from the shaft extension.

b. For single bearing generators, remove the capscrews and hardened washers holding the drive discs to the drive hub. (See Figure 10.) (NOTE: Capscrew removal can most easily be accomplished by starting at the bottom and removing the capscrews in a clockwise sequence.) Remove all drive discs (and spacers if any).

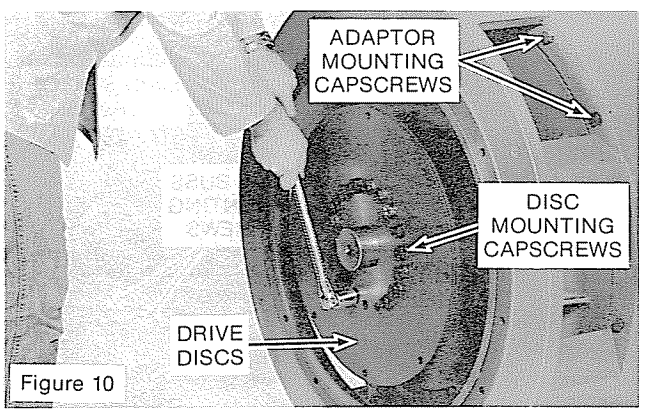

Figure 10

4. a. For two bearing generators, remove the capscrews holding the drive end bracket to the generator and remove the bracket.

b. For single bearing generators, remove the capscrews holding the SAE adaptor to the generator and remove the adaptor. (See Figure 11.)

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN DRIVE END BRACKET OR SAE ADAPTOR REMOVAL.

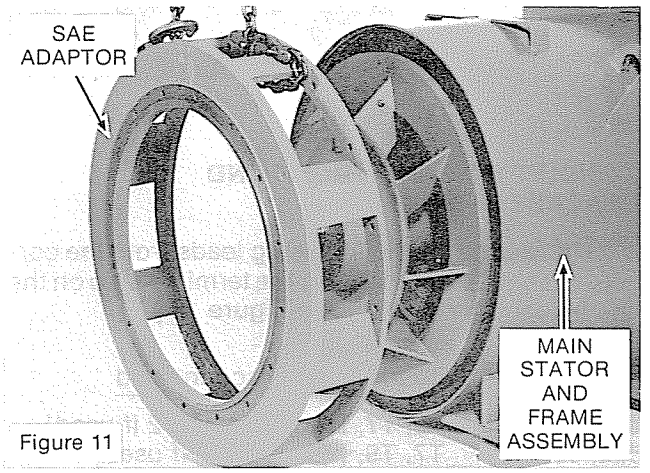

Figure 11

5. Using a rotor lifting fixture and a suitable hoist, carefully remove the rotor assembly from the main stator and frame assembly through the drive end. (See Figure 12.)

CAUTION: SPECIAL CARE SHOULD BE USED IN THE ROTOR ASSEMBLY REMOVAL, OR WINDING DAMAGE COULD RESULT.

WARNING

DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

SERVICE

DISASSEMBLY

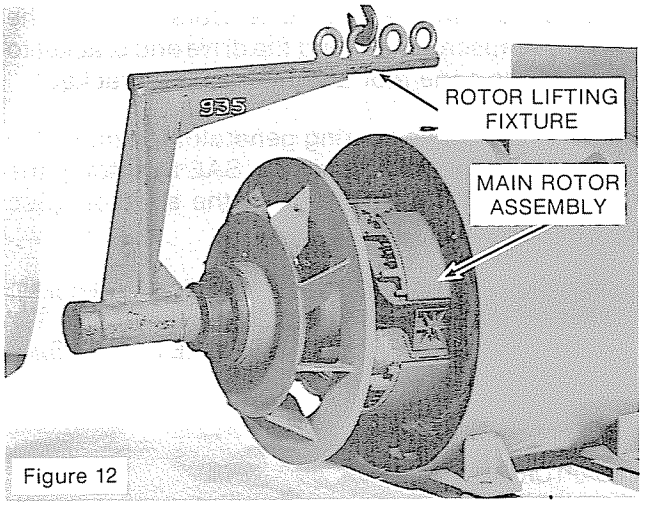

Figure 12

CONDUIT BOX AND FRONT END BRACKET REMOVAL

1. Disconnect the following leads from the corresponding points on the terminal strip on the regulator panel: (See Figure 13.)

Frame Size	Leads to be Disconnected
360, 440, 500	T0, T7, E3, [CT-1, CT-2 if used]
502, 680	T7, T9, [CT-1, CT-2 if used]
682	T0, T7 E1, E3, [CT-1, CT-2 if used]

NOTE: The above lead combinations are used on the standard generators; other leads may have to be removed depending on the particular application.

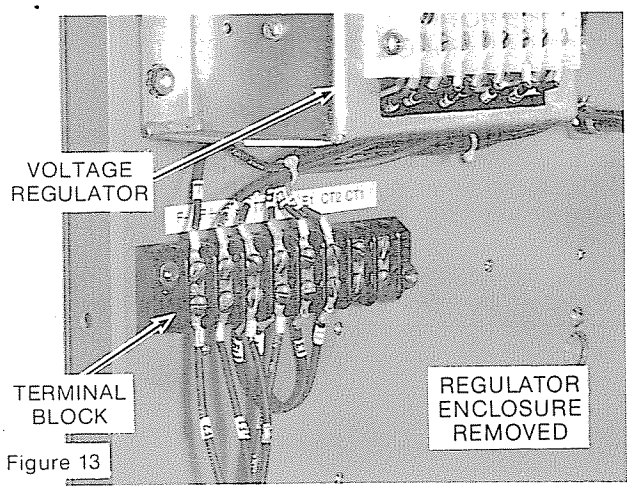

Figure 13

2. On generators with buss bars, disconnect all main stator leads bolted to the buss bar assembly, making sure all leads are marked for identification before removal. (See Figure 14.)

3. a. On generators with four buss bars (T1, T2, T3, T0), remove the capscrew, flat washer and lockwasher mounting the red insulating channel to the front end bracket. Remove the buss bar support mounting capscrews and lockwashers. Remove the buss bar assembly. Remove the capscrews and lockwashers mounting the neutral buss bar to the support.

   b. On generators with six buss bars (T1, T2, T3, T4, T5, T6), remove the capscrews and lockwashers mounting the buss bar support to the front end bracket. Remove the buss bar assembly (T1, T2 and T3). The neutral buss bar assembly (T4, T5 and T6) can remain in the bottom of the conduit box.

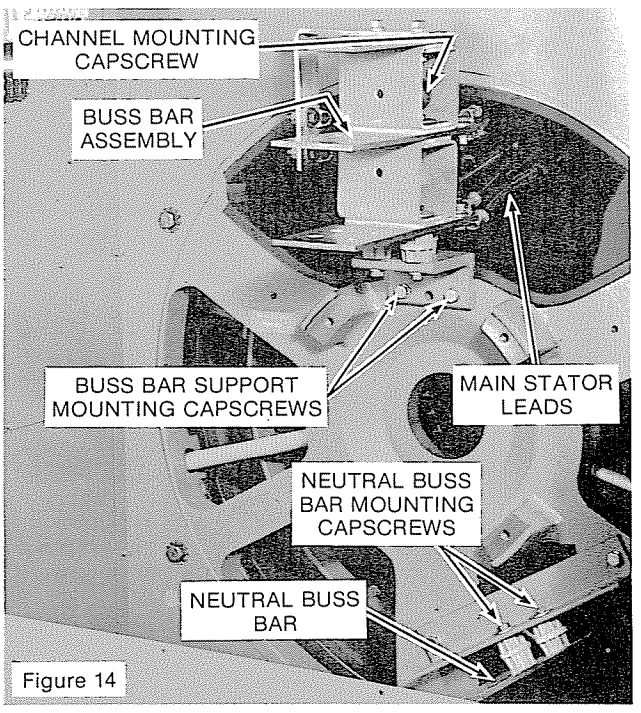

Figure 14

4. Remove the capscrews and starwashers holding the conduit box and front end bracket to the main stator assembly. (See Figure 15.) Lift off the conduit box.

5. On 680, 682 Frame generators, remove the one additional mounting capscrew at the bottom of the front end bracket. (See Figure 16.)

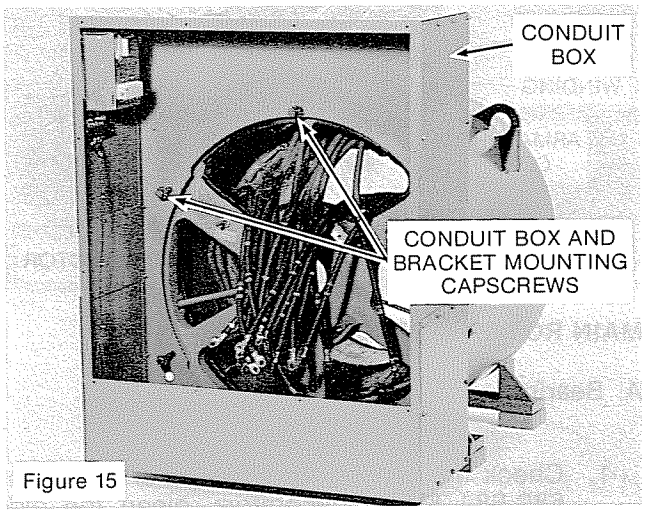

Figure 15

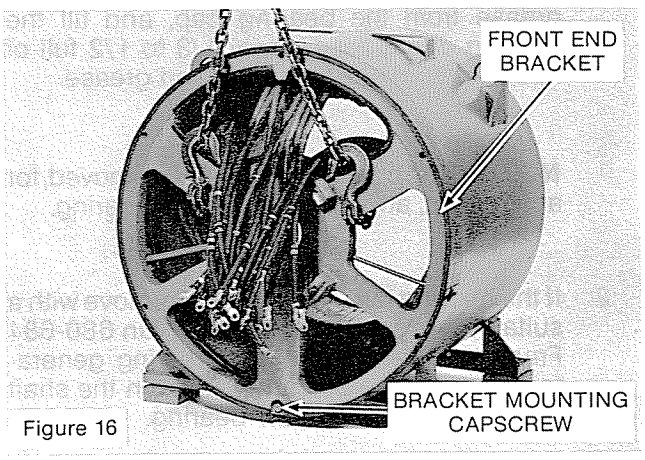

Figure 16

6. Remove the front end bracket from the main stator assembly. (See Figure 17.)

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE FRONT END BRACKET REMOVAL.

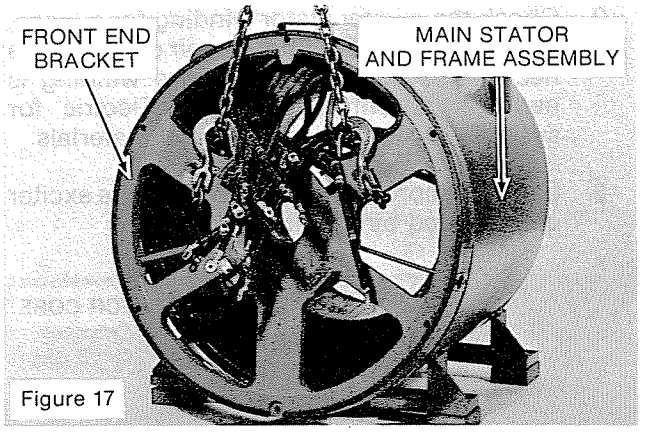

Figure 17

SERVICE

INSPECTION

EXCITER INSPECTION

A. Exciter Stator

1. Clean dust and dirt from the stator winding with a soft cloth or brush. (See Figure 18.) (See cleaning methods under Preventative Maintenance.)

2. Check the exciter stator winding for a loose, frayed, or burnt winding. Repair or replace as necessary. If field repair of the winding is necessary, contact Marathon Electric for special winding procedures and materials.

3. Look for score marks in the bore of the exciter core caused by rubbing.

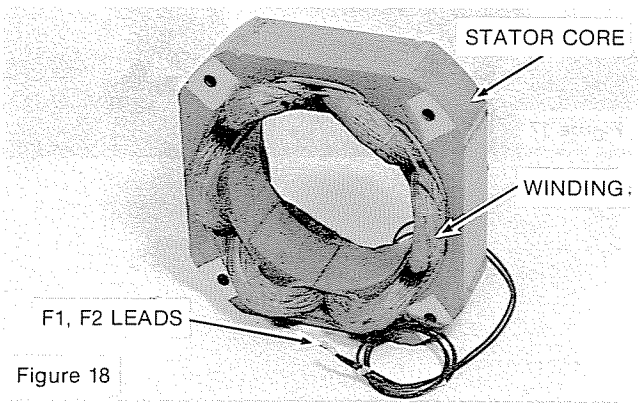

Figure 18

B. Exciter (Rotor) Armature

1. Clean all metal parts with an approved cleaning solvent.

2. Clean dust and dirt from the exciter armature and rectifier assembly with a soft cloth or brush. (See Figure 19.) (See cleaning methods.)

3. Check the exciter armature for burrs on the mating surfaces.

4. Check the rectifiers and surge protector for proper operation. (See Troubleshooting Section.) Replace defective parts.

5. Check the exciter armature and rectifier assembly for a loose, frayed, or burnt winding or loose connections. Repair or replace as necessary. If field repair of the winding is necessary, contact Marathon Electric for special winding procedures and materials.

6. Look for score marks on the outside diameter of the armature core caused by rubbing.

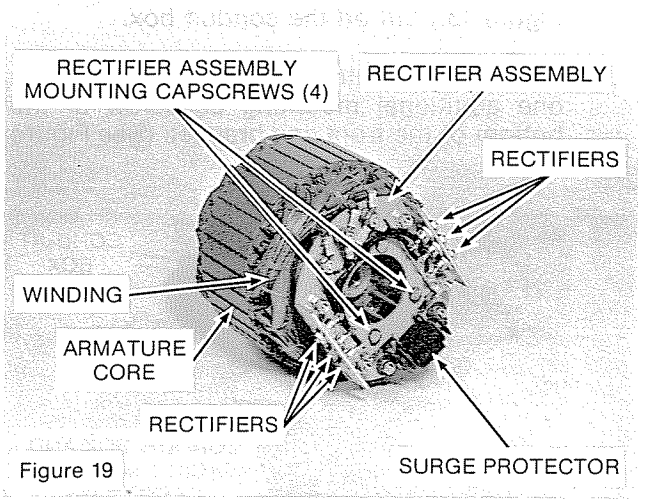

Figure 19

MAIN ROTOR INSPECTION

A. Bearing

1. Check the bearing for damage or wear. On 680-684 Frame generators, clean the old grease from the bearing cap, and fill the bearing cap grease cavity 1/3 to 1/2 full of new multipurpose lithium based grease.

NOTE: If the bearing needs to be removed, for any reason, always install a new bearing.

2. If the bearing is to be replaced, remove with a suitable puller. (See Figure 20.) On 680-684 Frame generators and two bearing generators, be sure the bearing cap is on the shaft before installing the new bearing.

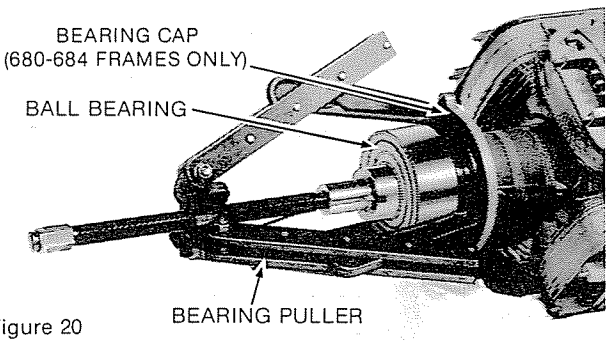

Figure 20

Heat the new bearing in an oven to a maximum temperature of 212° F (100° C). Apply a thin coat of clean lubricating oil to the press-fit area of the rotor shaft. Using asbestos gloves, install the bearing over the end of the shaft until it seats against the shaft shoulder. (See Figure 21.) The bearing should slide on the shaft and be seated without excessive force. If the bearing binds on the shaft before being fully seated, a piece of tubing, slightly larger than the press-fit area, can be used to drive the bearing into place. Using light taps with a soft mallet, apply pressure to the inner race only.

CAUTION: UNDER NO CIRCUMSTANCES SHOULD PRESSURE BE APPLIED TO THE OUTER RACE OF THE BEARING, AS PERMANENT BEARING DAMAGE COULD RESULT.

Allow the bearing to cool for one hour before attempting to assemble the generator.

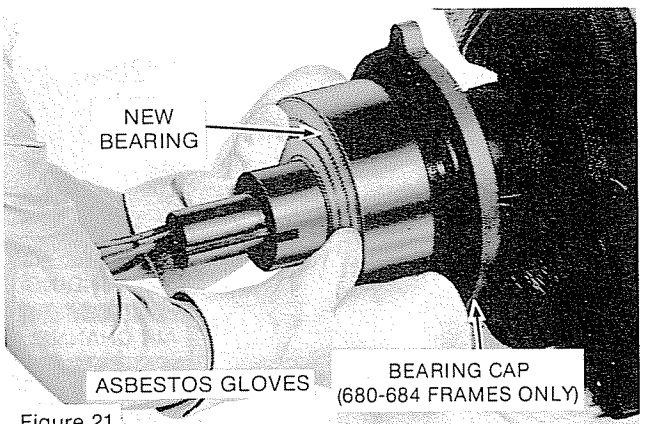

Figure 21

B. Drive Hub (Single Bearing Generators Only)

1. Check the drive hub for cracks or stripped drive disc mounting holes. Replace the hub if defective.

2. If the hub is to be replaced, mark the fan and hub for alignment to ensure proper balance after reassembly. Remove the fan mounting capscrews and belleville washers and move the fan back away from hub. (See Figure 22.) Install a suitable puller to the hub. Remove the setscrew in the hub over the key. Using a torch, rapidly heat the hub at the outer diameter while tightening the puller. (This must be done rapidly before the heat can expand the shaft.) Remove the hub. (Check the fan for defects according to Section C.)

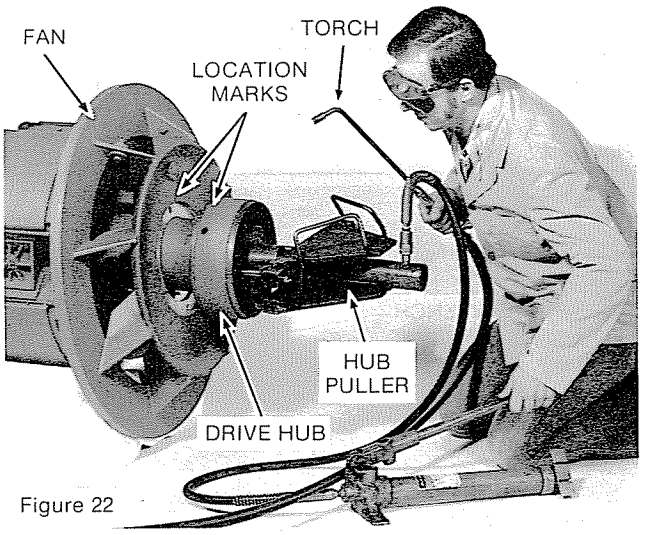

Figure 22

Mark the new hub in the same place as the old hub relative to the keyway. Heat the new hub in an oven to 500° -600° F (260° -316° C). Be sure that the fan is still on the shaft. Using asbestos gloves, slide the hub over the key in the shaft until it seats against the shaft shoulder. (See Figure 23.)

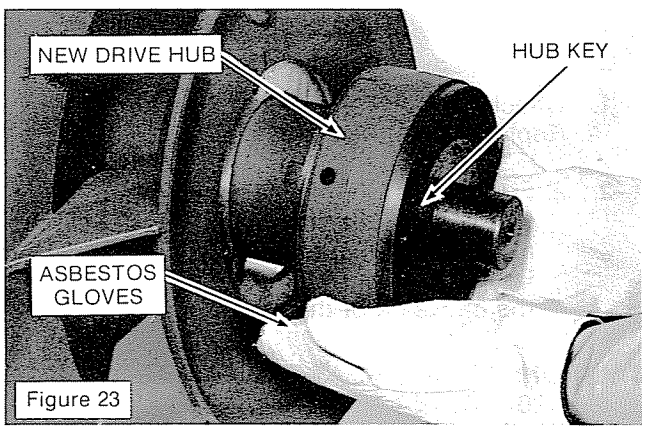

Figure 23

Allow the hub to cool for one hour. After the hub has cooled, tighten the setscrew in the hub to 50 ft-lbs (68 N.m) torque. Match the alignment marks on the fan and hub and mount the fan with the capscrews and belleville washers. (See Figure 24.) Torque the capscrews per Figure 49. (See Figure 25.)

SERVICE

INSPECTION

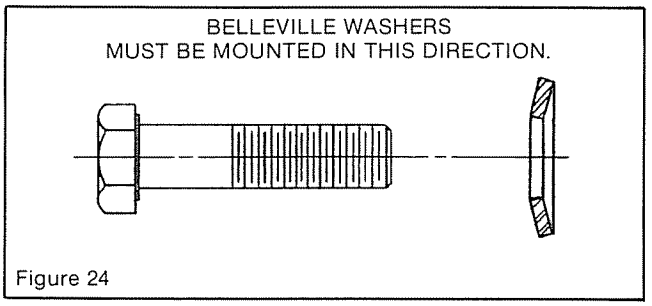

Figure 24

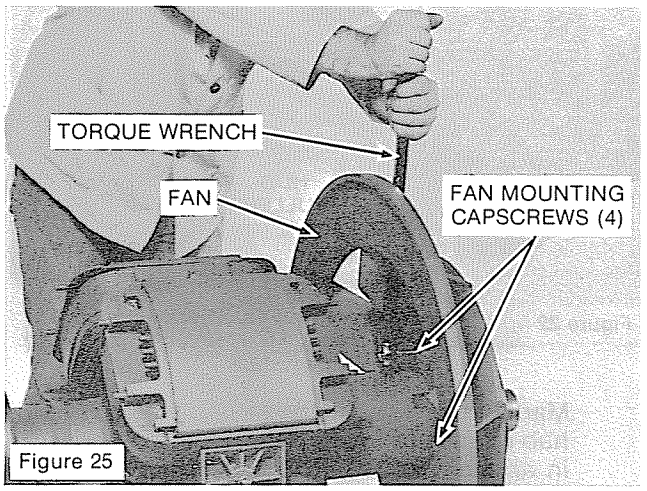

Figure 25

Rebalancing of the rotor assembly is not necessary if only the hub is replaced and the fan is mounted in the same location relative to the hub.

C. Fan

1. Check the fan for cracks or broken blades. Replace the fan if defective.

2. a. For two-bearing generators, remove the drive end bearing cap. (See bearing removal instructions above.) Remove the fan setscrews. Using a torch, rapidly heat the backside of the fan.

CAUTION: DO NOT HEAT THE FAN ABOVE 400-500° F (204-260° C) AS THIS WILL REMOVE THE TEMPER FROM THE FAN.

Using asbestos gloves, slide the fan off the shaft. Heat the new fan in an oven to 400° - 500° F (204° -260° C). Using asbestos gloves, slide the fan over the key in the shaft until it seats against the shaft shoulder. Allow the fan to cool for one-half hour. After the fan has cooled, tighten the setscrews in the fan to 17 ft-lbs (23 N.m) torque. Install the bearing cap and a new bearing according to the bearing assembly instructions above.

b. For single bearing generators, remove the hub according to the above drive hub removal instructions. Slide the fan off the shaft. Slide the new fan on the shaft making sure the fan mounting surface is toward the drive hub. Mount the hub according to the drive hub assembly instructions above. Mount the fan to the drive hub with the cap-screws and belleville washers (see Figure 24). Torque the capscrews per Figure 49. (See Figure 25.)

3. The rotor assembly must be rebalanced if a new fan has been installed.

D. Main Rotor Core and Windings

1. Clean all metal parts with an approved cleaning solvent. Remove dust and dirt from the rotor windings with a soft cloth or brush. (See Figure 26.) (See cleaning methods.)

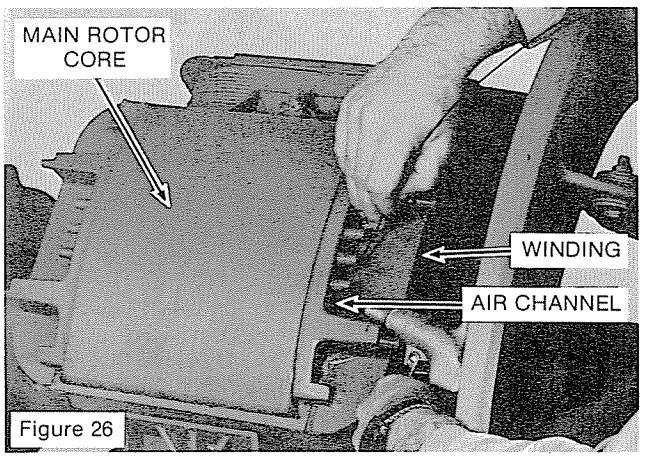

Figure 26

Remove any accumulated dust or dirt in the winding air channels with a piece of wire or with low-pressure, moisture-free air.

CAUTION: IF A PIECE OF WIRE IS USED FOR CLEANING THE AIR CHANNELS; CARE MUST BE TAKEN NOT TO SCRATCH THE WINDING AS THIS COULD CAUSE AN INSULATION FAILURE..

2. Check the rotor for loose, frayed, or burnt windings. A defective rotor winding must be rewound by Marathon Electric. The rotor assembly must be rebalanced after any rework or repair has been completed.

Katolight Service - Master Repair Manual - Page 908

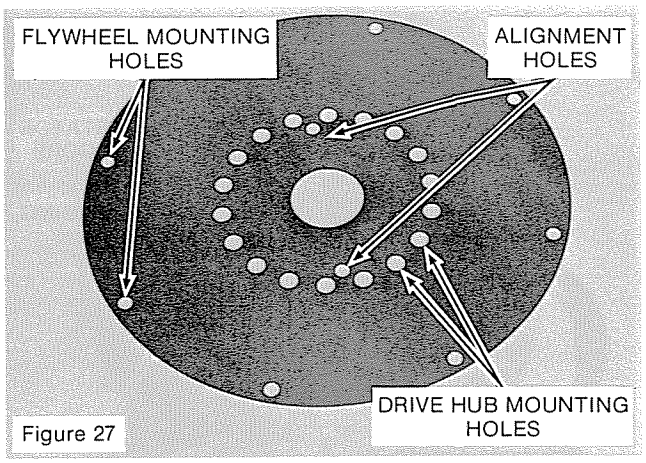

Figure 27

F. Drive Discs (Single Bearing Generators Only)

1. Inspect the drive discs for distorted or bent edges. (See Figure 27.) Inspect for worn mounting holes. Replace all defective discs as necessary.

2. Inspect the drive disc mounting capscrews for damaged threads. Replace capscrews if damaged.

FRONT END BRACKET INSPECTION

1. Remove the filler and drain grease pipes and the grease plugs from the bracket. (See Figure 28.)

2. Clean the end bracket, grease pipes, and capscrews in an approved solvent to remove all dust, dirt, and grease. Dry the parts thoroughly with compressed air.

3. Inspect the capscrews for stripped threads and replace if defective.

4. Inspect the end bracket for cracks and burred or rough mating surfaces. Inspect the bearing bore for burrs or wear. If the bracket shows excessive bearing bore wear, it should be replaced.

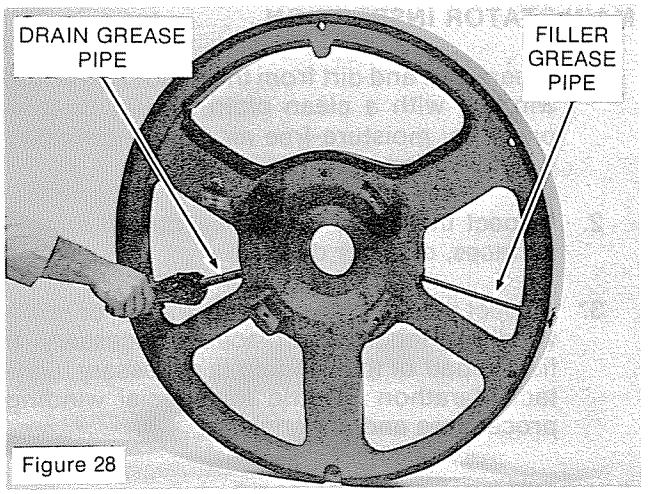

Figure 28

DRIVE END BRACKET OR SAE ADAPTOR INSPECTION

1. For two-bearing generators, remove the grease plugs from the bracket.

2. Clean the bracket or adaptor, capscrews and screen assembly in an approved solvent to remove all dust, dirt, and grease. (See Figure 29.) Dry the parts thoroughly with compressed air.

3. Inspect the capscrews for stripped threads and replace if defective.

4. Inspect the bracket or adaptor for cracks and burred or rough mating surfaces.

5. For two-bearing generators, inspect the bearing bore for burrs or wear. If the drive end bracket shows excessive bearing bore wear, it should be replaced.

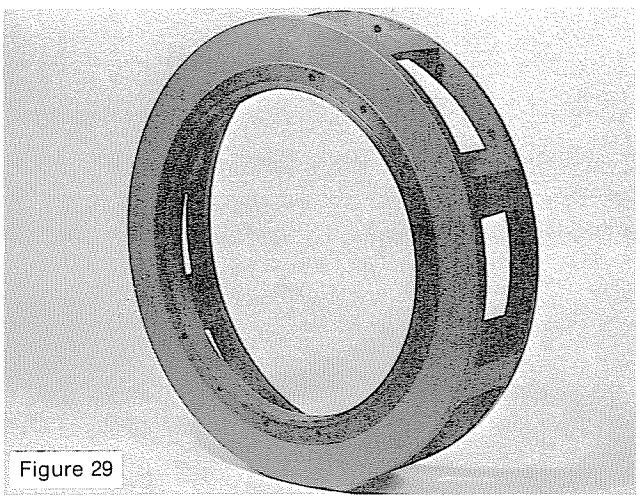

Figure 29

SERVICE

INSPECTION

MAIN STATOR INSPECTION

1. Clean dust and dirt from the stator frame and winding with a clean cloth, brush, or low-pressure, moisture-free air. (See Figure 30.) (See cleaning methods.)

2. Inspect the frame for cracks, burred mating surfaces, or other damage.

3. Inspect the stator for a loose, frayed, or burnt winding. Repair or replace as necessary. If field repair of the winding is necessary, contact Marathon Electric for special winding procedures and materials.

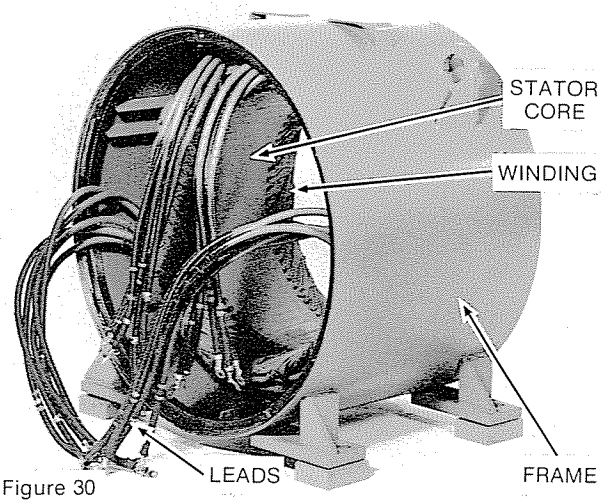

Figure 30

CONDUIT BOX AND VOLTAGE REGULATOR INSPECTION

1. Clean dust from the conduit box and the louvered cover with a clean cloth, brush, or low-pressure, moisture-free air. (See cleaning methods.)

2. Clean dust and dirt from the voltage regulator with a clean cloth, brush, or low-pressure, moisture-free air. (See cleaning methods.) Check all electrical connections for loose or broken wires.

CONDUIT BOX AND FRONT END BRACKET INSTALLATION

1. Fill the grease cavity of the front end bracket 1/3 to 1/2 full of new multipurpose lithium based grease. See "Lubrication Instructions" in this manual. Assemble all grease pipes and plugs in the bracket.
2. Install two guide pins in the main stator assembly frame. Align the bracket mounting holes to the guide pins and slide the bracket over the pins. (See Figure 31.) On 680, 682 Frame generators, install the bottom capscrew. (See Figure 32.)

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE FRONT END BRACKET INSTALLATION.

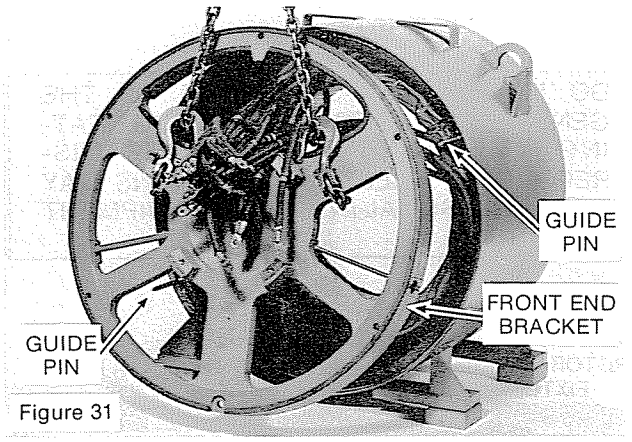

Figure 31

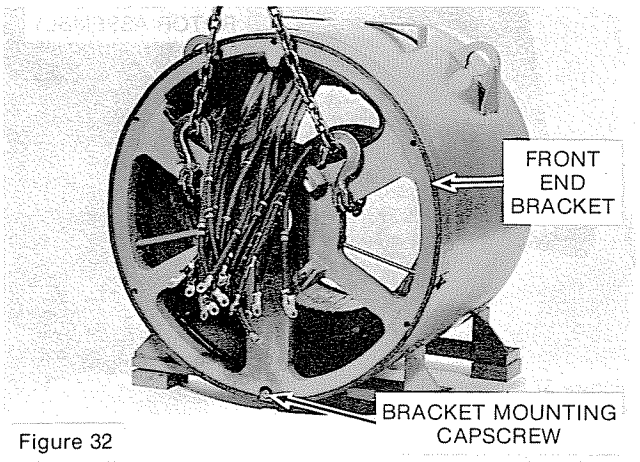

Figure 32

3. Insert two capscrews and starwashers through the conduit box and mount the conduit box to the bracket and main stator and frame assembly. (See Figure 33.) Remove the two guide pins and insert the remaining capscrews and starwashers.

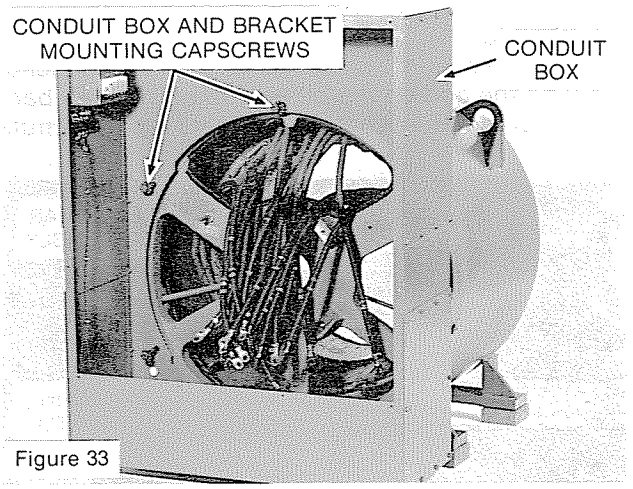

Figure 33

4. a. On generators with four buss bars (T1, T2, T3, T0), mount the neutral buss bar to the support with the capscrews and lockwashers. (See Figure 34.) Mount the buss bar assembly to the front end bracket with the capscrews and lockwashers. Assemble the capscrew, flat washer, and lockwasher through the red insulating channel into the front end bracket.

   b. On generators with six buss bars (T1, T2, T3, T4, T5, T6), mount the buss bar assembly support to the front end bracket with the capscrews and lockwashers.

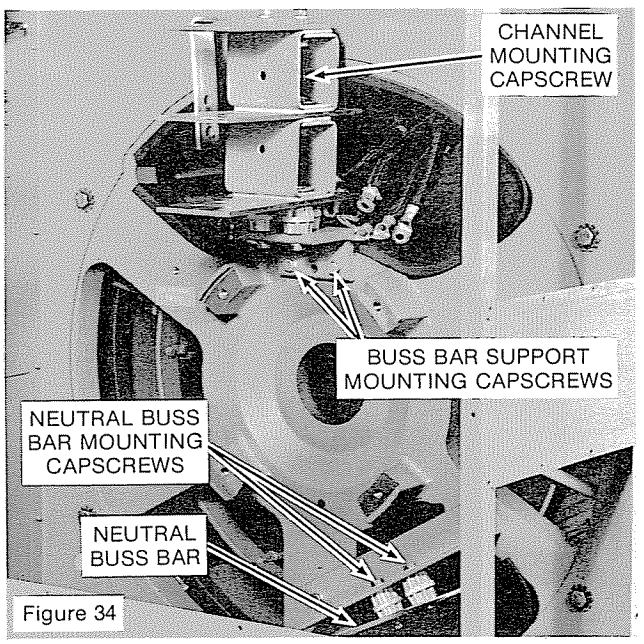

Figure 34

SERVICE

ASSEMBLY

5. On generators with buss bars, connect the main stator leads to the appropriate buss bar according to the lead markings. Insert a flat washer on the bolt, then assemble one terminal to the buss bar with the bolt and flat washer. (See Figure 35.) Insert a second lead on the bolt on the other side of the buss bar, then a flat washer, lockwasher, and locknut.

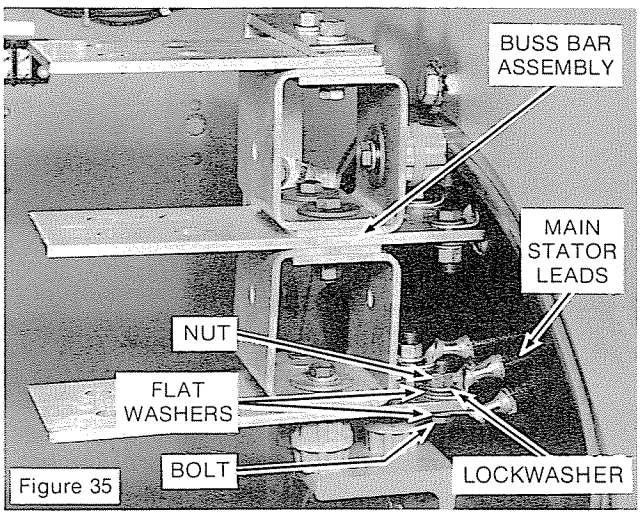

Figure 35

6. Connect the following leads to the corresponding points on the terminal strip on the regulator panel: (See Figure 36).

Frame Size	Leads to be Connected
360, 440, 500	T0, T7, E3, [CT-1, CT-2 if used]
502, 680	T7, T9, [CT-1, CT-2 if used]
682	T0, T7, E1, E3, [CT-1, CT-2 if used]

7. Install regulator enclosure.

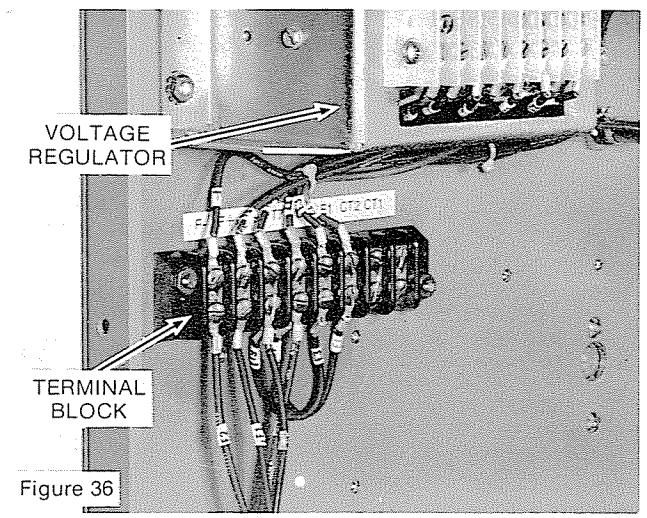

Figure 36

NOTE: These lead combinations are used on the standard generator; other leads may have to be reconnected depending on the particular application.

MAIN ROTOR INSTALLATION

1. Using a rotor lifting fixture and a suitable hoist, carefully install the rotor assembly into the main stator assembly through the drive end. (See Figure 37.) Carefully feed the rotor leads through the front end bracket shaft hole as the rotor is installed.

CAUTION: SPECIAL CARE SHOULD BE USED IN THE ROTOR ASSEMBLY INSTALLATION, OR WINDING DAMAGE COULD RESULT.

WARNING

DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

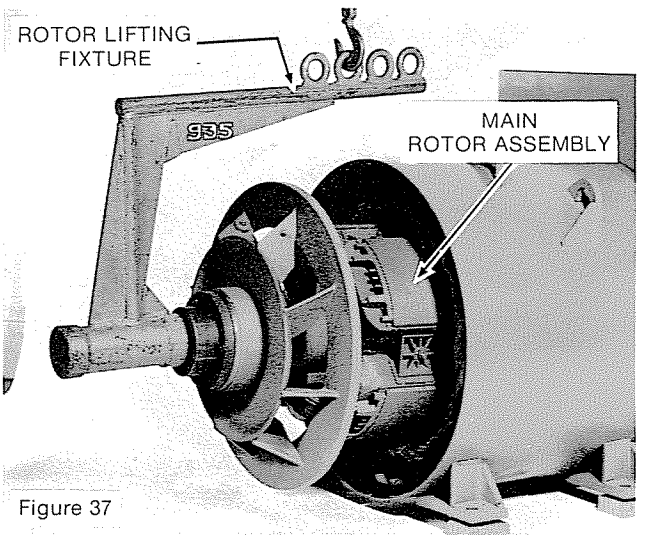

Figure 37

2. a. For two bearing generators, insert guide pins in the rear bearing lock holes. Fill the grease cavity of the drive end bracket 1/3 to 1/2 full of new miltipurpose lithium based grease. Assemble all grease plugs in the bracket. Mount the bracket on the bearing and guide the bearing lock pins through the bracket holes. Align the drive end bracket and mount with the capscrews. Remove one bearing lock guide pin and insert a capscrew and lockwasher into the bearing lock and tighten. Remove the remaining guide pin and replace with the remaining capscrew and lockwasher.

   b. For single bearing generators, pilot the SAE adaptor to the fan and secure to the main stator and frame assembly with capscrews torqued per Figure 49. (See Figure 38.) It may be necessary to raise the rotor assembly slightly to allow the mounting of the SAE adaptor.

CAUTION: ON LARGE GENERATORS, A HOIST AND LIFTING STRAP SHOULD BE USED TO ASSIST IN THE DRIVE END BRACKET OR THE SAE ADAPTOR ASSEMBLY.

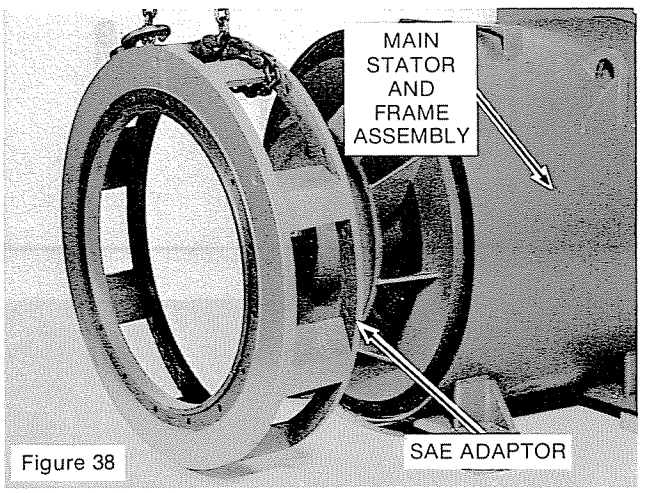

Figure 38

3. a. For two-bearing generators, install the drive coupling half or sheave on the shaft extension.

   b. For single bearing generators, insert a guide stud into the drive hub. Position all spacers (if any), then all drive discs, one at a time until all discs are installed. (See Figure 39.) Make sure that all disc mounting holes at the inner and outer diameter are properly aligned. Secure the discs with the capscrews and hardened washers torqued per Figure 49. (See Figure 40 for torquing sequence.)

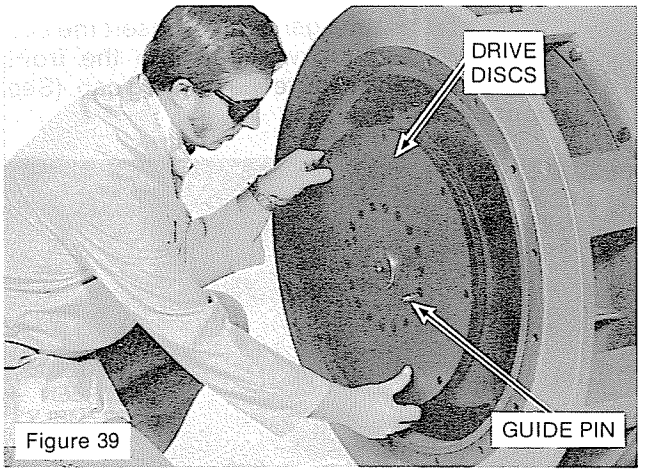

Figure 39

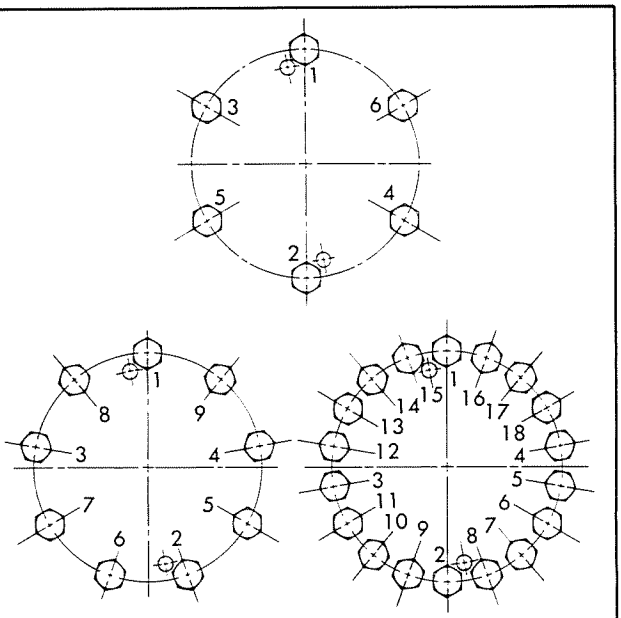

Torque the bolts in the above sequence according to the correct bolt pattern.

Then check the torque in each bolt in a clockwise direction around the bolt circle to insure that all the bolts are properly torqued.

Figure 40

SERVICE

ASSEMBLY

4. Mount the screen assembly on the drive end bracket or the SAE adaptor and tighten the bolts. (See Figure 41.)

5. On 680, 682 Frame generators, insert the two capscrews and lockwashers into the front end bracket and secure the bearing cap. (See Figure 42.)

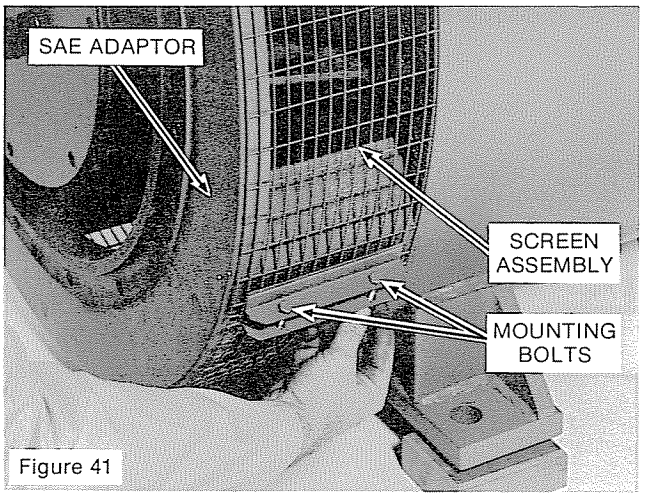

Figure 41

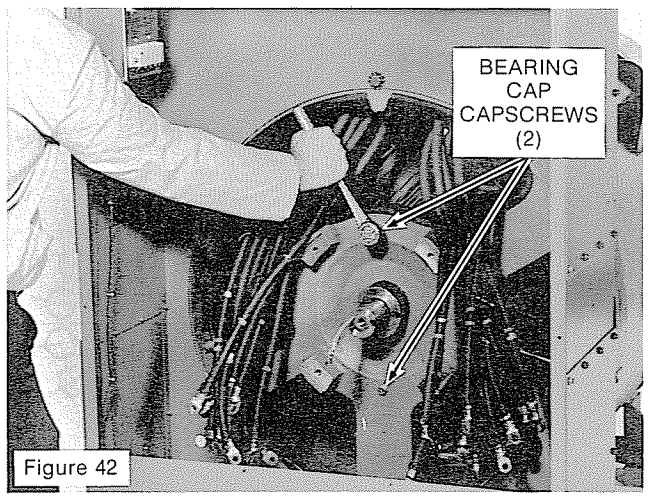

Figure 42

EXCITER INSTALLATION

1. Install the exciter key in the armature bore keyway. Attach a wire to the main rotor leads and feed the wire through the armature bore and out the lead hole in the aluminum standoff plate. Mount the armature on the end of the shaft and align the key in the armature bore to the keyway in the shaft. Slide the armature on the shaft while feeding the main rotor leads through the lead hole in the aluminum standoff plate. (See Figure 43.)

Insert the capscrew and belleville washer (see Figure 44) through the mounting hole in the aluminum standoff plate and secure to the shaft (see Figure 45). Tighten the capscrew until the armature seats on the shaft. Torque the capscrew per Figure 49.

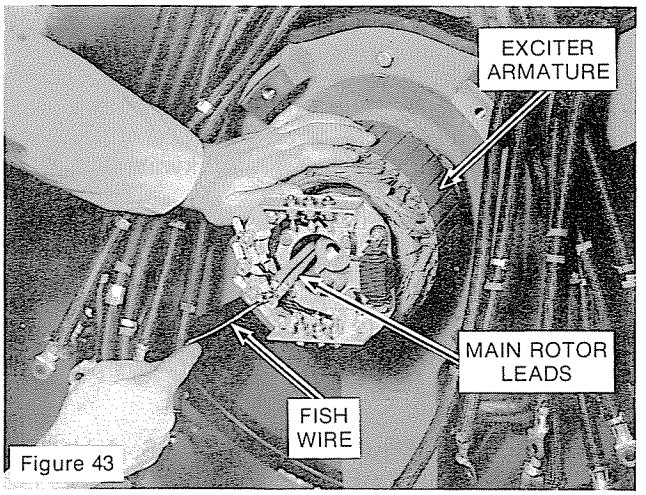

Figure 43

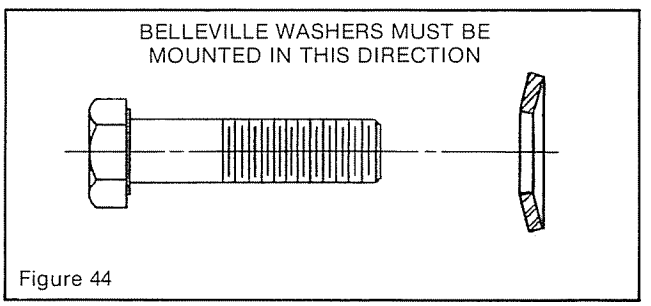

Figure 44

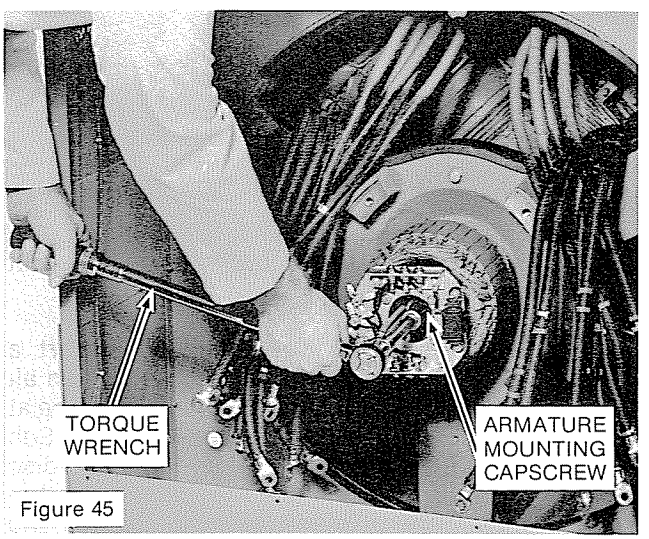

Figure 45

2. Connect both main rotor leads coming out of the aluminum standoff plate to the rectifier aluminum angle; one to each angle. (See Figure 46.)

3. Mount the exciter stator on the front end bracket mounting pads and align the mounting holes, noting the position of "top front" previously marked for reference (field leads at inside bottom). (See Figure 47.) Align the lead shield on the exciter stator and mount with the capscrews and belleville washers (see Figure 44). Torque the capscrews per Figure 49. Install new lead fasteners to secure F1 and F2 to the front end bracket and conduit box.

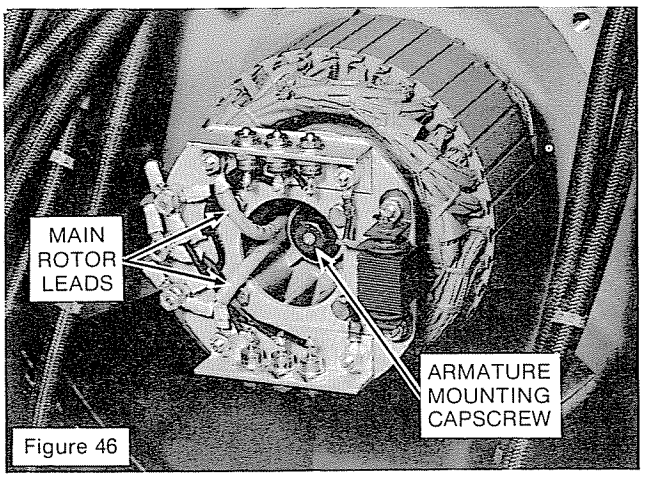

Figure 46

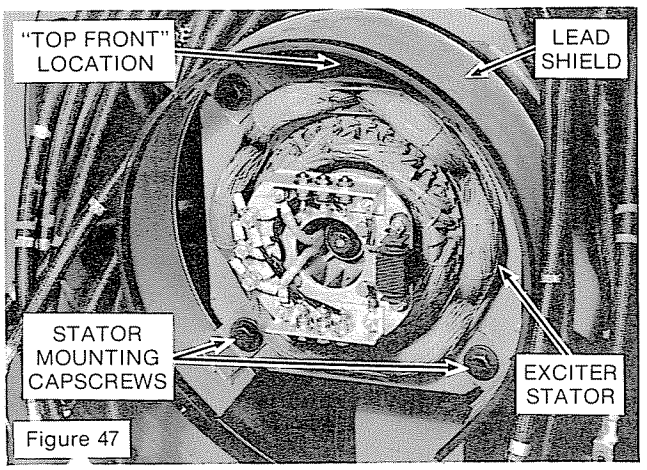

Figure 47

4. Connect the F1 and F2 leads to the corresponding F+ and F− terminals on the terminal block on the regulator panel and install the regulator enclosure. (See Figure 48).

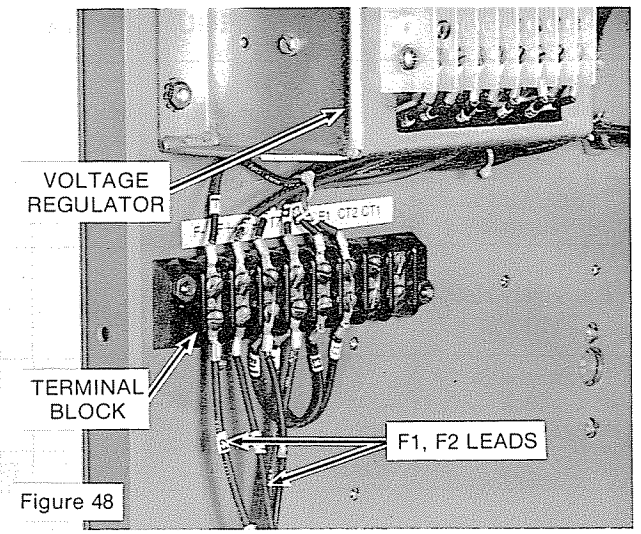

Figure 48

ASSEMBLY TO PRIME MOVER

1. Attach a suitable hoist to the generator lifting lugs, and move the generator until the generator foot mounting holes are aligned with the base and slightly above.

2. a. For two-bearing generators, align the coupling halves or sheaves between the generator and the prime mover by adding shims under the feet.

   b. For single bearing generators, if the screen assembly is mounted on the adaptor, remove the mounting bolts and remove the screen (see Figure 50). (NOTE: Do not remove the drip cover from the screen assembly if so equipped.) Insert two guide pins in the flywheel and two in the flywheel housing. Adjust the generator position until the drive discs are piloted in the flywheel. Remove the guide pins and secure the discs with Grade 8 place bolts and hardened washers or Grade 8 capscrews and heavy series lockwashers. (Torque per Figure 49.)

WARNING

DO NOT APPLY ANY FORCE TO THE GENERATOR FAN FOR LIFTING OR ROTATING THE GENERATOR ROTOR. DISREGARDING THESE INSTRUCTIONS MAY CAUSE PERSONAL INJURY OR EQUIPMENT DAMAGE.

NOTES:
1. Based on use of clean, dry threads.
2. Torque reduced by 10% when engine oil is used as a lubricant.
3. Torque reduced by 20% if new plated capscrews are used.
4. Capscrews threaded into aluminum may require reductions in torque of 30% or more.

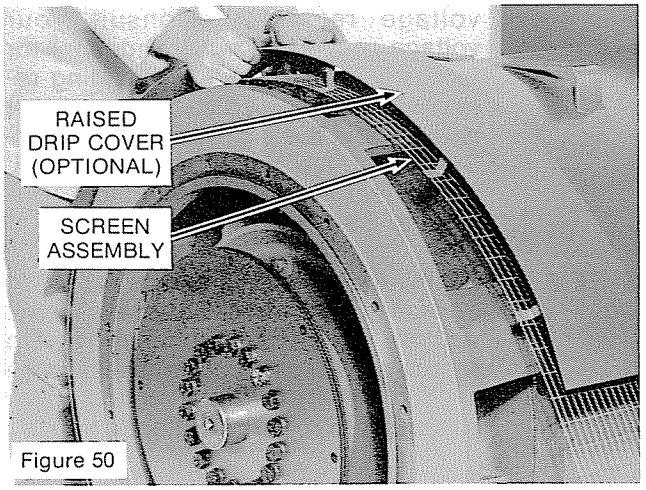

Figure 50

Position the generator so that the SAE adaptor mates with the flywheel housing.

CAUTION: DO NOT FORCE THE ALIGNMENT OF THE UNITS. SHIFT THE GENERATOR FROM SIDE TO SIDE OR RAISE OR LOWER WITH A LIFTING DEVICE AS NECESSARY.

It may be necessary to use shims under the mounting feet of either the generator or the prime mover to obtain proper alignment; use the same shims as removed under disassembly or proceed as follows: Using the extreme bottom four capscrews, mount the SAE adaptor to the flywheel housing. With a .0015 to .002 inch feeler gauge at the extreme top adaptor to flywheel housing to fit, raise the generator or lower the prime mover until the gauge is snug. Relieve just enough to release the feeler gauge and torque the remaining SAE adaptor capscrews to the flywheel housing.

Mount the screen assembly and tighten the mounting bolts.

3. Shim under the generator feet for proper support, ensuring that the generator mounting surfaces are level.

4. Install the mounting bolts which secure the generator to the mounting base.

5. For two bearing generators, assemble the coupling halves or sheave belts between the generator and the prime mover. (Follow the coupling manufacturer's instructions for assembly.)

6. Connect all existing conduit or ducting to the conduit box.

7. Connect all electrical load leads to the generator leads (or buss bars) inside the conduit box.

8. Check the exciter air gap (gap between the exciter armature and stator) by inserting a .010 inch feeler gauge in the gap and rotating it around the armature diameter to ensure that a minimum air gap is available. (See Figure 51.) If the feeler gauge cannot be rotated one full revolution, then check for a "cocked" exciter stator or loose stator mounting capscrews.

   NOTE: On single bearing units, the exciter air gap cannot be checked properly until the generator is mounted to the prime mover.

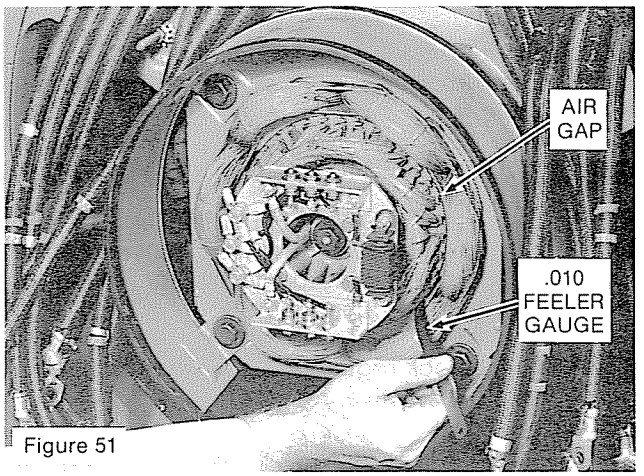

Figure 51

9. Mount the louvered conduit box cover.

10. Relubricate the bearing according to the lubrication instructions. (See Figure 52.)

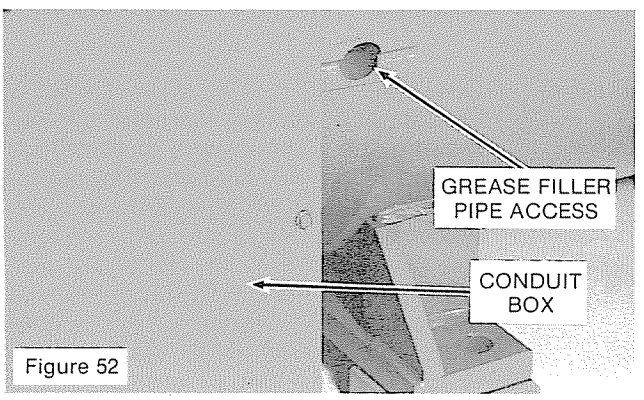

Figure 52

TROUBLE SHOOTING

GENERATOR PRODUCES NO VOLTAGE

THIS SECTION IS DIVIDED BY SYMPTOMS:

GENERATOR PRODUCES NO VOLTAGE

GENERATOR PRODUCES LOW VOLTAGE

GENERATOR PRODUCES HIGH VOLTAGE

GENERATOR VOLTAGE IS FLUCTUATING

WARNING

RESIDUAL VOLTAGE IS PRESENT AT THE GENERATOR LEADS AND AT THE REGULATOR PANEL CONNECTIONS, EVEN WITH THE REGULATOR FUSES REMOVED. CAUTION MUST BE OBSERVED OR SERIOUS PERSONAL INJURY OR DEATH CAN RESULT. CONSULT QUALIFIED PERSONNEL WITH ANY QUESTIONS.

NOTE: Always include the Model Number and Serial Number of your generator when corresponding with Marathon Electric

GENERATOR DOES NOT PRODUCE VOLTAGE

STEP 1 SHUT DOWN THE GENERATOR SET and remove conduit box cover. Check main generator leads for loose or broken connections.

STEP 2 Check regulator fuses with ohmmeter. If defective, replace.

STEP 3 Start up generator. Measure voltage at voltage regulator terminals 3 and 4. The voltmeter reading should exceed 5V ac. If it does, proceed to Step 4. If it does not, check continuity of wiring from connections 3 and 4 to the voltage source. If wiring is okay, — flashing is required. See the section on Field Flashing, page 15.

STEP 4 SHUT DOWN THE GENERATOR SET. Disconnect voltage regulator by removing the connections to terminals F+ and F- on the regulator. Connect a common 12 volt storage battery to the disconnected wires keeping polarity the same. Start up the generator set. With the generator at rated speed, read the voltage output of the unit on a voltmeter. Following these steps, if the reading is one-half or greater of the rated output when there is no load on the generator, the problem is in the voltage regulator. Consult your voltage regulator owner's manual for further information. If the reading remains near zero, the voltage regulator is okay, and the problem is further on. SHUT DOWN THE GENERATOR. Reconnect the voltage regulator. Proceed to Step 5.

STEP 5 Examine the rotating exciter for loose or broken lead wires. Be sure to check that all six rectifier connections are secure as well as all other wires on the exciter. Repair, replace or tighten as necessary. Proceed to Step 6.

STEP 6 Test each rectifier with an ohmmeter. Remove the bolted leadwire from one rectifier at the terminal stud. Test the resistance between the disconnected leadwire and the rectifier base. Make sure you have a good connection. Note the reading and reverse the ohmmeter probes. One reading should be high and the other low if the rectifier is good. If this is the case, reconnect that rectifier and proceed to the next, repeating the procedure until all six rectifiers have been checked. If the high and low readings are not achieved, the rectifier is defective and must be replaced. Torque the new rectifier to 20-30 in-lbs. Please note that two different types of rectifiers (with different polarities) are used on your unit. If all rectifiers are good, proceed to Step 7.

STEP 7 Locate the surge protector and disconnect one of the two bolted surge protector leads. With an ohmmeter, measure the resistance between the disconnected lead and the other surge protector terminal. Reverse the ohmmeter probes and repeat the test. If a high resistance is measured in both directions, proceed to Step 8. If resistance is low in one or both directions, replace the surge protector.

STEP 8 Check windings for continuity. If opens or shorts are found in the exciter armature or stator, replace the necessary component. If the condition is found in the main generator stator or rotor, major repair or generator replacement is probably required.

TROUBLE SHOOTING

NOTE: Always include the Model Number and Serial Number of your generator when corresponding with Marathon Electric

GENERATOR PRODUCES LOW VOLTAGE

STEP 1 Low voltage condition should be verified at the generator load leads with an auxiliary voltmeter.

STEP 2 SHUT DOWN THE GENERATOR SET and remove conduit box cover. Check main generator leads for correct connection.

STEP 3 Start up the generator set. Verify correct speed (1800 rpm at 60 Hertz and 1500 rpm at 50 Hertz) with a tachometer.

STEP 4 Make sure generator load does not exceed nameplate capacity. Verify this with a "clamp-on" ammeter on the main load leads. Current in any line must not exceed nameplate amps.

STEP 5 Adjust the range pot on the voltage regulator in the extreme clockwise direction to increase generator voltage as necessary.

STEP 6 Be sure the voltage adjust rheostat is adjusted, as necessary, to increase generator voltage.

STEP 7 SHUT DOWN THE GENERATOR SET. Check the sensing tap on the voltage regulator to be sure it is correct. On some applications, full line voltage is not used for regulatory sensing. Refer to the generator connection diagram.

STEP 8 Disconnect the voltage regulator by removing the connections to terminals F+ and F- on the regulator. Connect a common 12 volt storage battery to the disconnected wires keeping the polarity the same. Start up the generator set. With the generator at rated speed, read the voltage output of the unit on a voltmeter. Following these steps, if the reading is one-half or greater of the rated output when there is no load on the generator, the problem is in the voltage regulator. Consult your voltage regulator owners' manual for further information. If the reading remains near zero, the voltage regulator is okay and the problem is further on. SHUT DOWN THE GENERATOR SET. Reconnect the voltage regulator.

STEP 9 Test each rectifier with an ohmmeter. Remove the bolted leadwire from one rectifier at the terminal stud. Test the resistance between the disconnected leadwire and the rectifier base. Make sure you have a good connection. Note the reading and reverse the ohmmeter probes. One reading should be high and the other low if the rectifier is good. If this is the case, reconnect that rectifier and proceed to the next, repeating the procedure until all six rectifiers have been checked. If the high and low reading is not achieved, the rectifier is defective and must be replaced. Torque the new rectifier to 20-30 in-lbs. Please note that two different types of rectifiers (with different polarities) are used on your unit. If the rectifiers are good, proceed to Step 10.

STEP 10 Locate the surge protector and disconnect one of the two bolted surge protector leads. With an ohmmeter, measure the resistance between the disconnected lead and the other surge protector terminal. Reverse the ohmmeter probes and repeat the test. If a high resistance is measured in both directions proceed to Step 11. If resistance is low in one or both directions, replace the surge protector.

STEP 11 Check the windings for continuity. If opens or shorts are found in the exciter armature or stator, replace the necessary component. If the condition is found in the main generator stator or rotor, major repair or generator replacement is probably required.

Katolight Service - Master Repair Manual - Page 919

TROUBLE SHOOTING

GENERATOR PRODUCES HIGH VOLTAGE
GENERATOR VOLTAGE IS FLUCTUATING

NOTE: Always include the Model Number and Serial Number of your generator when corresponding with Marathon Electric

GENERATOR PRODUCES HIGH VOLTAGE

STEP 1 High voltage condition should be verified at the generator load leads with an auxiliary voltmeter.

STEP 2 SHUT DOWN THE GENERATOR SET and remove conduit box cover. Check main generator leads for correct connection.

STEP 3 Start up the generator set. Verify correct speed (1800 rpm at 60 Hertz and 1500 rpm at 50 Hertz) with a tachometer.

STEP 4 Adjust the range pot on the voltage regulator in the counterclockwise direction to decrease generator voltage as necessary.

STEP 5 Be sure the voltage adjust rheostat is adjusted as necessary, to reduce generator voltage.

STEP 6 SHUT DOWN THE GENERATOR SET. Check the sensing tap on the voltage regulator to be sure it is correct. On some applications, full line voltage is not used for regulator sensing. Refer to the generator connection diagram.

STEP 7 Check the polarity of the rectifiers on the rotating rectifier. All three rectifiers on each aluminum standoff should have the identical part number. Note, however, that two different types of rectifiers (with different polarities and different part numbers) are used on each aluminum angle.

STEP 8 Disconnect the voltage regulator by removing the connections to terminals F+ and F- on the regulator. Connect a common 12 volt storage battery to the disconnected wires keeping the polarity the same. Start up the generator set. With the generator at rated speed, read the voltage output of the unit on a voltmeter. If the reading is one-half or greater of the rated output when there is no load on the generator, the problem is in the voltage regulator. Consult the voltage regulator owners' manual for further information. Shut down the generator. Reconnect the voltage regulator.

GENERATOR VOLTAGE IS FLUCTUATING

STEP 1 Adjust voltage regulator stability clockwise for increased stability.

STEP 2 Verify engine governor performance with a tachometer to insure stable engine speed.

STEP 3 SHUT DOWN THE GENERATOR SET and remove conduit box cover. Check all wiring for loose connections. Be sure that voltage adjust rheostat is properly connected and working.

STEP 4 Disconnect voltage regulator by removing the connections to terminals F+ and F- on the regulator. Connect a common 12 volt storage battery to the disconnected wires keeping polarity the same. Start up the generator set. With the generator at rated speed, read the voltage output of the unit on a voltmeter. Following these steps, if the reading is one-half or greater of the rated output and does not fluctuate when there is no load on the generator, the problem is in the voltage regulator. Consult your regulator owners' manual for further information. If the reading continues to fluctuate, the problem is further on. Shut down the generator. Reconnect the voltage regulator. Proceed to Step 5.

STEP 5 Check windings for continuity. If opens or shorts are found in the exciter armature or stator, replace the necessary component. If the condition is found in the main generator stator or rotor, major repair or generator replacement is probably required.

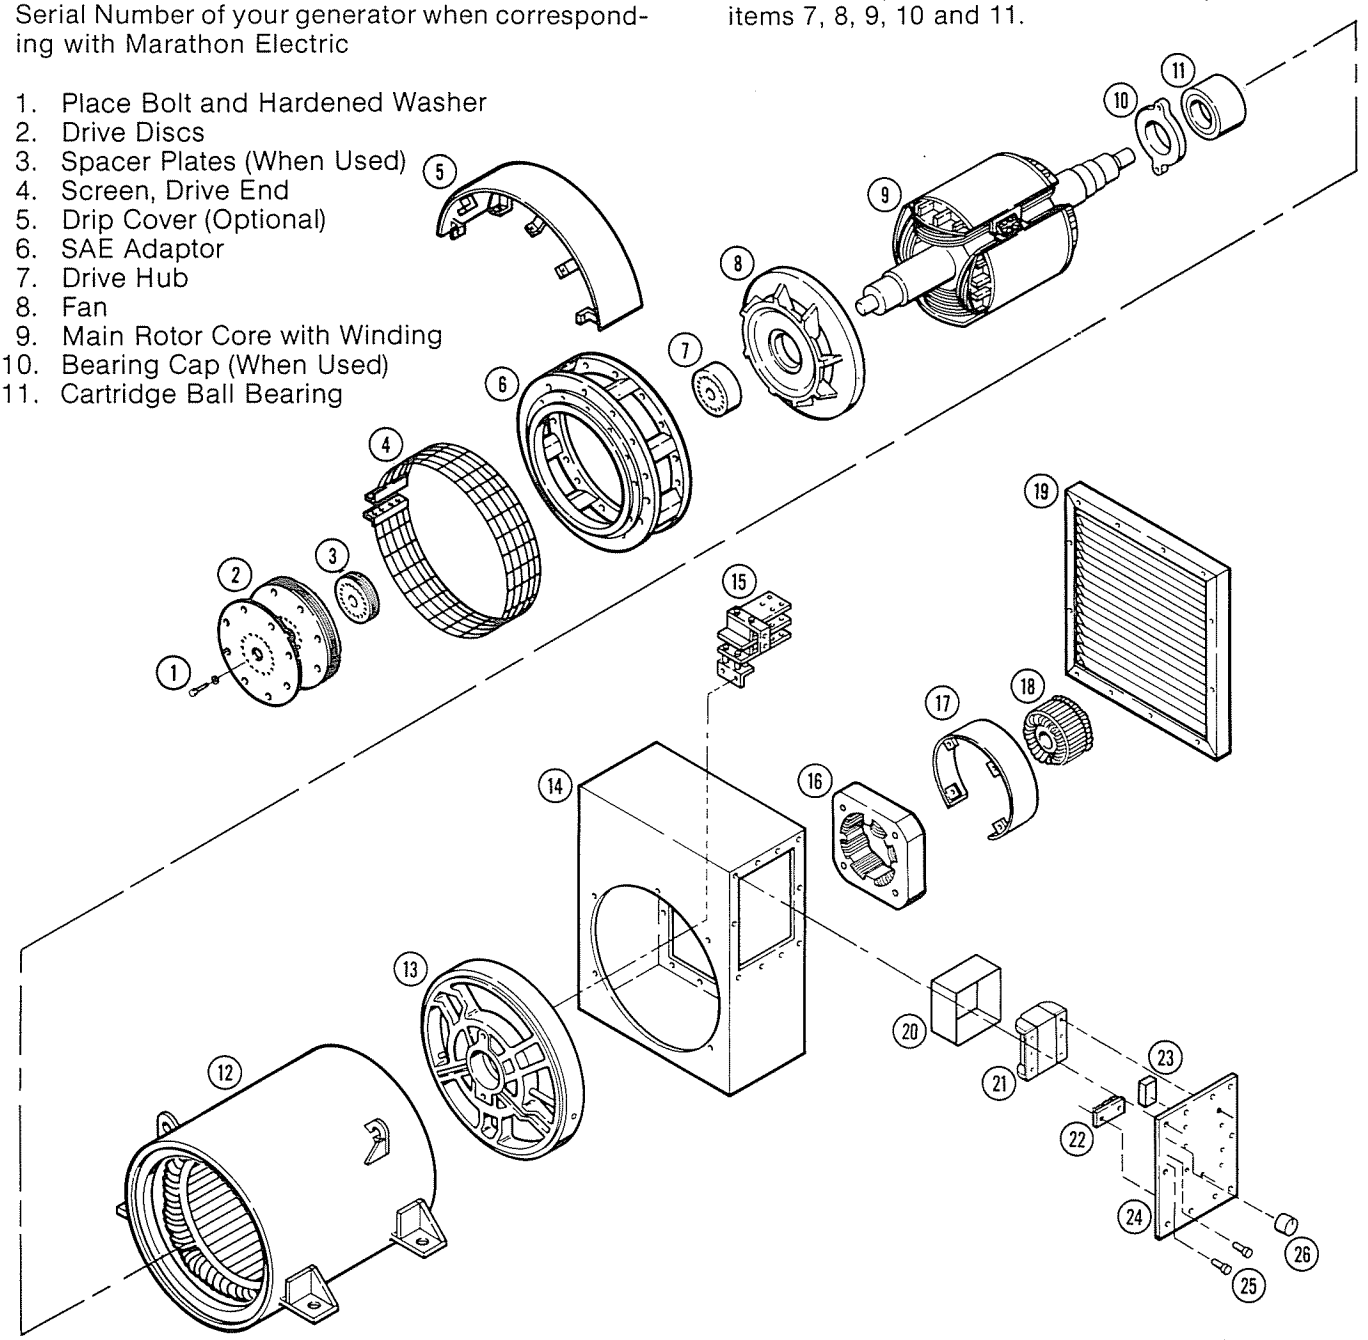
PARTS LIST

SINGLE BEARING GENERATOR PARTS LIST

NOTE: Always include the Model Number and Serial Number of your generator when corresponding with Marathon Electric

NOTE: Complete Main Rotor Assembly consists of items 7, 8, 9, 10 and 11.



1. Place Bolt and Hardened Washer
2. Drive Discs
3. Spacer Plates (When Used)
4. Screen, Drive End
5. Drip Cover (Optional)
6. SAE Adaptor
7. Drive Hub
8. Fan
9. Main Rotor Core with Winding
10. Bearing Cap (When Used)
11. Cartridge Ball Bearing
12. Main Stator and Frame Assembly with Winding
13. Front End Bracket
14. Conduit Box
15. Buss Bar Assembly (When Used)
16. Exciter Stator Assembly with Winding
17. Lead Shield
18. Exciter (Rotor) Armature and Rectifier Assembly with Winding
19. Louvered Conduit Box Cover
20. Regulator Enclosure
21. Voltage Regulator
22. Terminal Block
23. Exciter Field Circuit Breaker
24. Regulator Panel
25. Fuses and Fuse Holders
26. Voltage Adjust Rheostat

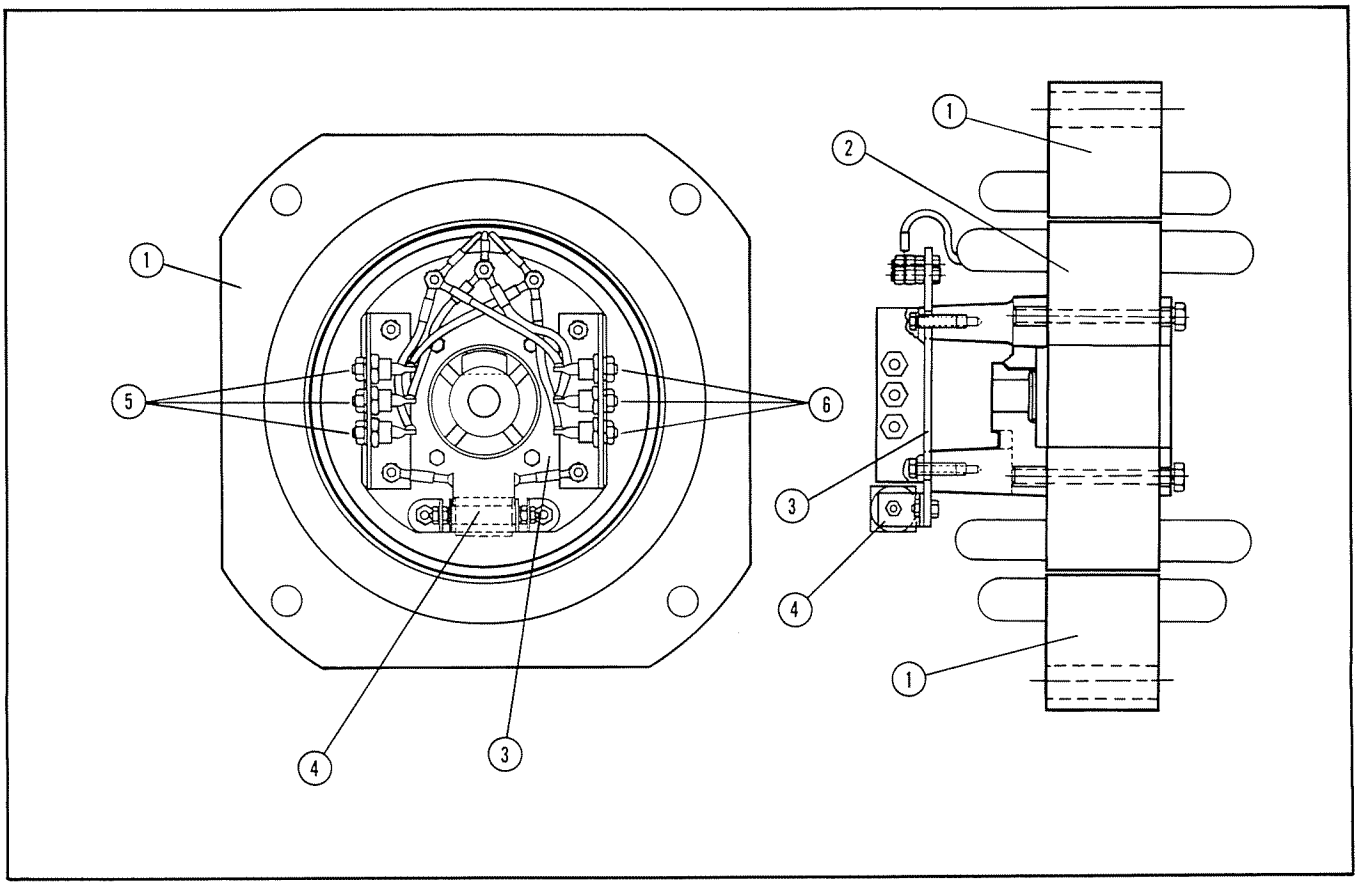
PARTS LIST

EXCITER (ROTOR) ARMATURE, STATOR AND RECTIFIER ASSEMBLY

Rectifier Mounting Torque 20-30 inch-pounds.

NOTE: Always include the Model Number and Serial Number of your generator when corresponding with Marathon Electric

NOTE: Diodes have distinct polarity and can not be interchanged.



1. Exciter Stator Assembly with Winding
2. Exciter (Rotor) Armature & Rectifier Assembly with Winding
3. Rectifier Assembly
4. Surge Protector
5. Rectifiers (Standard Polarity)
6. Rectifiers (Reverse Polarity)

PARTS LIST

RECOMMENDED SPARE PARTS

Marathon Electric recommends the following spare parts to minimize inconvenience. Always include the Model Number and Serial Number of your generator when corresponding with Marathon Electric.

ITEM	QTY.	PART NUMBER
Voltage Regulator	1	
KR-4F		A-505156
KR-4FM		A-510632
KR-4FFX		A-511682
KR-4FFMX		A-511683
KR-7F		A-505308
KR-7FM		A-510633
KR-7FFX		A-511684
KR-7FFMX		A-511685
Bearing	1	Refer to factory
Surge Protector	1	A-A509431-1
Rectifier (Standard Polarity)	3	A-A9589-6
Rectifier (Reverse Polarity)	3	A-A9681-2
Fuse	6	A-505369
Fuse Holder	2	A-505310
Voltage Adjust Rheostat	1	A-508445
Exciter Field Circuit Breaker		
For KR-4 Regulators	1	A-511162-1
For KR-7 Regulators	1	A-511162-3
Exciter Assembly (In remote areas)	1	Refer to factory

Refer to factory for other voltage regulators.

Parts may be ordered direct from:

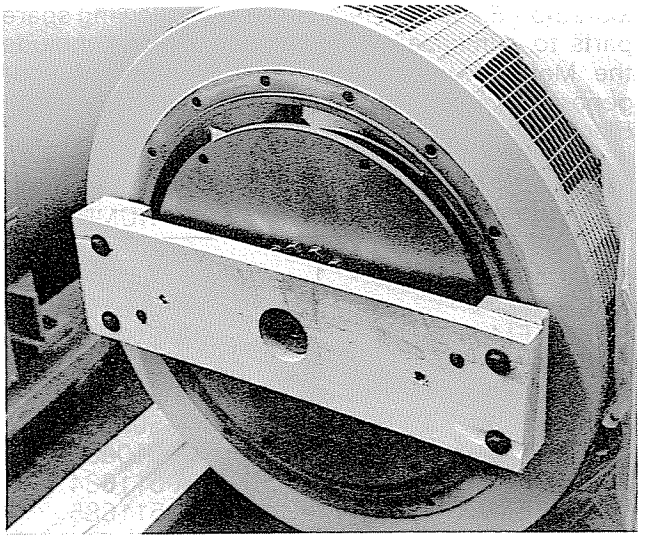
Marathon Electric Mfg. Corp.
P.O. Box 1407
Wausau, Wis. 54401

Phone (715) 675-3311

SHIPPING INSTRUCTIONS

SHIPPING INSTRUCTIONS

When installed, single bearing generator rotors are supported on the drive end by the drive discs bolted to the engine flywheel. When the engine is removed, the rotor must be supported by an appropriate fixture to prevent main rotor, main stator or exciter damage (see photo). Before shipping any generator, the main rotor must be supported by the adaptor using an appropriate fixture.



WARNING

DO NOT ATTEMPT TO TRANSPORT ANY GENERATOR WITHOUT PROPER ROTOR SUPPORT, OR EXTENSIVE EQUIPMENT DAMAGE CAN OCCUR.

SAFETY

PLEASE REMEMBER SAFETY FIRST. If you are not sure of the instructions or procedures contained herein, seek qualified help before continuing.

This service manual emphasizes the safety precautions necessary during the installation, operation, and maintenance of your MagnaPLUS generator. Each section of this manual has caution and warning messages. These messages are for your safety, and the safety of the equipment involved. If any of these cautions or warnings is not readily understood, seek clarification from qualified personnel before proceeding.

Before any service work is done, disconnect all power sources and lock out all controls to prevent an unexpected start-up of the generator set driver. Proper grounding (earthing) of the generator frame and distribution system in compliance with local and national electrical codes and specific site requirements must be provided. These safety precautions are necessary to prevent potential serious personal injury, or even death.

The hazards associated with lifting or moving your MagnaPLUS generator are pointed out in the installation and maintenance sections. Incorrect lifting or moving can result in personal injury or damage to the unit.

Prior to start-up of the unit ensure that all generator leads are properly connected to the generator link board located inside the connection box. Always assume that there will be voltage present at the generator terminals whenever the generator's shaft is rotating**,** and proceed accordingly. Residual voltage is present at the generator terminals and at the automatic voltage regulator panel connections even with the regulator fuse removed. Caution must be exercised, or serious injury or death can result.

This manual is not intended to be a substitute for properly trained personnel. Installation and repairs should only be attempted by qualified, trained people. The cautions and warnings point out known conditions and situations that are potentially hazardous. Each installation may well create its own set of hazards

When in doubt, ask. Questions are much easier to handle than mistakes caused by a misunderstanding of the information presented in this manual.

RECEIVING AND STORAGE

RECEIVING AND STORAGE

Upon receipt of the generator, it is recommended that it be carefully examined for possible shipping damage. The generator was given to the freight carrier in good condition; thus, the carrier is responsible for the product from the factory dock to the destination. Any damage should be noted on the freight bill before accepting the shipment. Any claims for damage must be promptly filed with the delivering carrier.

UNPACKING AND HANDLING

Carefully read all instruction tags shipped with the unit. When lifting, attach an overhead crane to the lifting lug(s) on the generator frame. Apply lifting forces in a vertical direction. When transporting single bearing generators, the generator's rotor must be adequately supported to prevent damage.

WARNING

THE LIFTING LUG (S) ON THE GENERATOR ARE DESIGNED TO SUPPORT THE GENERATOR ONLY. DO NOT LIFT A COMPLETE GENERATOR AND DRIVER ASSEMBLY BY MEANS OF LIFTING LUG (S) ON THE GENERATOR. PERSONAL INJURY OR EQUIPMENT DAMAGE MAY RESULT.

STORAGE

In the event that the generator is not immediately installed on its prime mover, it is recommended that the unit be stored indoors in a clean, dry area, which is not subject to rapid changes in temperature and humidity. If the generator is stored for a long period of time, the generator should be tested, cleaned and dried as required before being put into service. See the maintenance section of this manual for further information. If the unit has been stored in an area where it has been subject to vibration, it is recommended that the bearing(s) be inspected and replaced as necessary.

PRINCIPLES OF OPERATION

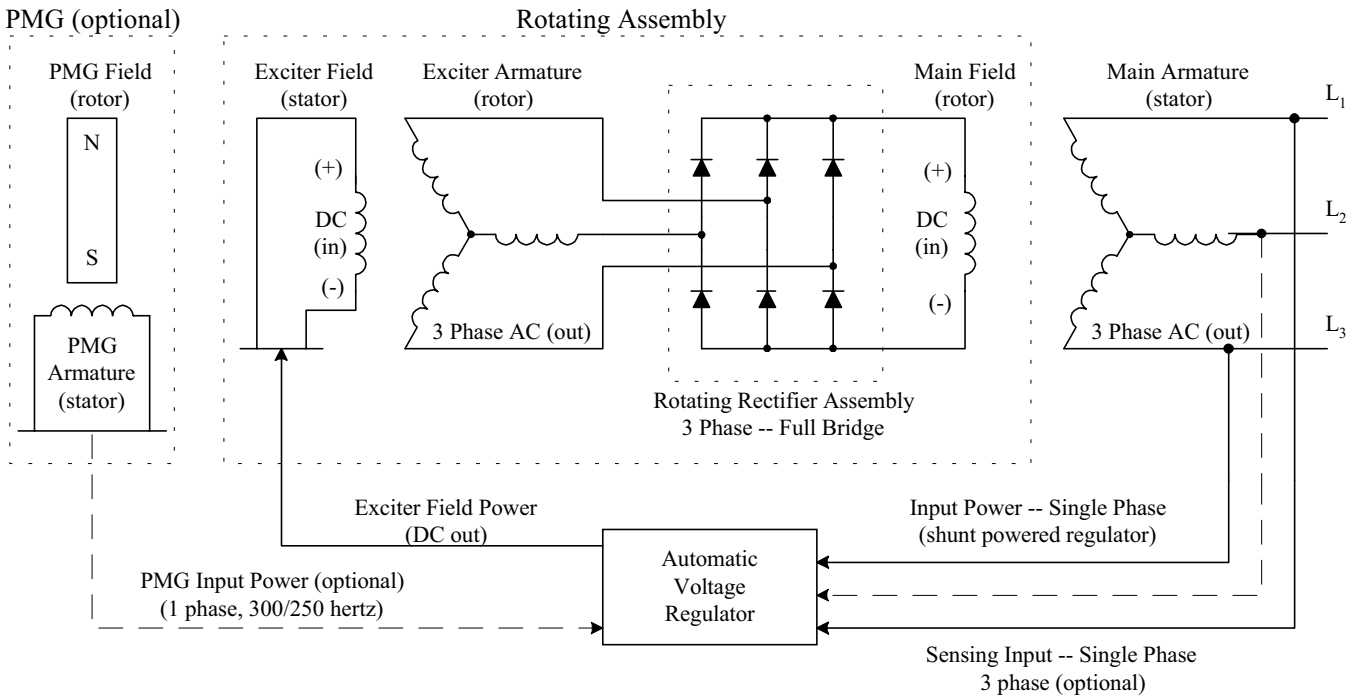

FIGURE 1 -- MagnaPLUS Circuit Diagram

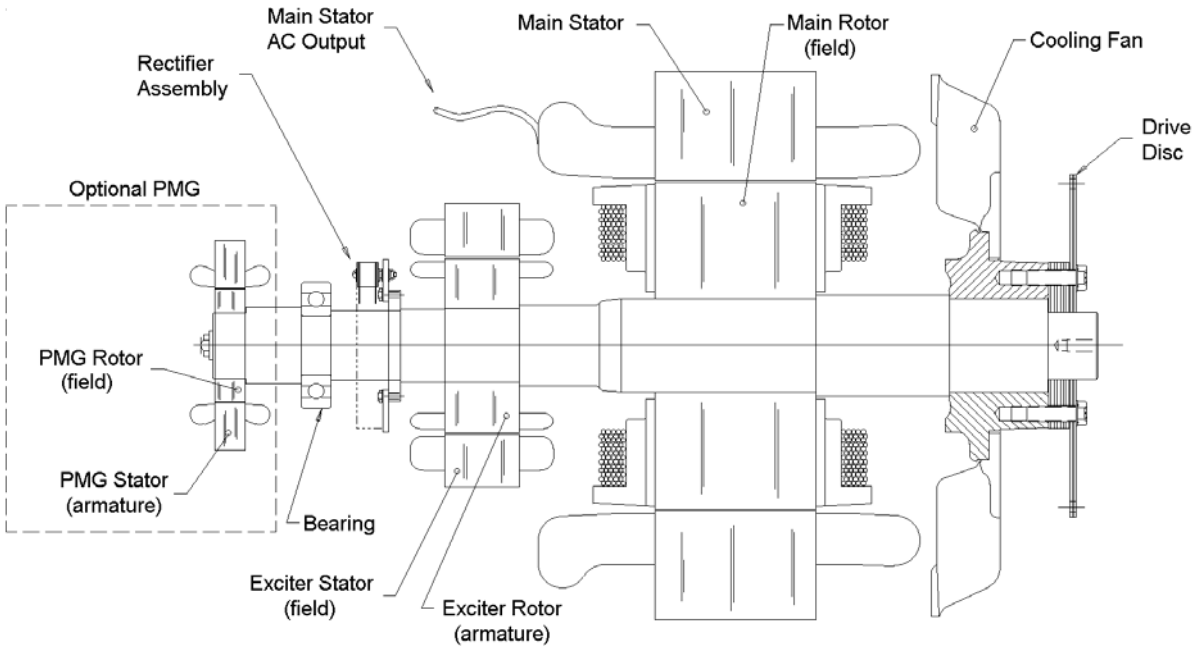

FIGURE 2 -- Typical MagnaPLUS Layout Diagram

PRINCIPLE OF OPERATION

MagnaPLUS generators are a brushless, self excited, and externally voltage regulated, synchronous AC generator. The generator is made up of six major components: main stator (armature), main rotor (field), exciter stator (field), exciter rotor (armature), rectifier assembly, and voltage regulator. In understanding the above terminology, note the following: stators are stationary, rotors rotate, a field is an electrical input, and an armature is an electrical output. These system components are electrically interconnected as shown in figure 1 and physically located as shown in figure 2.

The generator's exciter consists of a stationary field and a rotating armature. The stationary field (exciter stator) is designed to be the primary source of the generator's residual magnetism. This residual magnetism allows the exciter rotor (armature) to produce AC voltage even when the exciter stator (field) is not powered. This AC voltage is rectified to DC by the rotating rectifier assembly and fed directly to the main rotor (field). As the generator shaft continues to rotate, the main rotor (field) induces a voltage into the generator's main stator (armature). At rated speed, the main stator's voltage produced by the residual magnetism of the exciter allows the automatic voltage regulator to function. The regulator provides voltage to the exciter resulting in a build-up of generator terminal voltage. This system of using residual magnetism eliminates the need for a special field flashing circuit in the regulator. After the generator has established the initial residual voltage, the regulator provides a controlled DC field voltage to the exciter stator resulting in a controlled generator terminal voltage.

Voltage Regulation

In the standard configuration (shunt excited), the automatic voltage regulator receives both its input power and voltage sensing from the generator's output terminals (See Figure 1). With the optional PMG configuration, the regulator receives input power from the PMG. The regulator automatically monitors the generator's output voltage against an internal reference set point and provides the necessary DC output voltage to the exciter field required to maintain constant generator terminal voltage. Adjusting the regulator's reference set point changes the generator's terminal voltage. Consult the regulator manual for specific adjustment and operating instructions.

MOTOR STARTING

When a motor is started, the motor draws a large surge of current. This starting current is equivalent to the motors locked rotor or stall current and is 5 to 10 times' normal full load current. When the generator supplies this in-rush of starting current, the generator voltage dips temporarily. If the motor is too large for the generator, the generator's voltage dips greater than 30 percent. This may result in the motor starter de-energizing or the motor stalling. MagnaPlus generators generally supply .3 to .4 horsepower per generator kW in motor starting capability. For specific data contact Katolight.

PARALLEL OPERATION

All MagnaPlus generators are built with 2/3 pitch main stator windings and full amortisseur (damper) windings. These features make the MagnaPlus generators suitable for parallel operation when equipped with the proper voltage regulators and voltage regulator accessories. Consult with the factory for further information relative to parallel operations.

NONLINEAR LOADING

Solid state electronic control devices (variable frequency drives, precision motor controls, battery chargers, etc.) utilize electronic switching circuits (thyristors, SCRs, Diodes, etc.). These switching circuits introduce high frequency harmonics, which distort the normal waveform of the generator. This creates additional heat in the generator windings and may cause the generator to over-heat. Problems that can occur are not limited to the generator. Poor wave shape may adversely effect various loads connected to the generator. Consult Katolight for further information relative to nonlinear loads.

INSTALLATION

PREPARATION FOR USE

Although the generator has been carefully inspected and tested in operation prior to shipment from the factory, it is recommended that the generator be thoroughly inspected. Check all bolts for tightness and examine the insulation on lead wires for chafing prior to proceeding with installation. Remove all shipping tapes, bags, skids and rotor support blocking. For two bearing units, rotate the shaft by hand to ensure that it rotates smoothly without binding.

WARNING

DISABLE AND LOCKOUT ANY ENGINE CRANKING DEVICES BEFORE ATTEMPTING TO INSTALL OR SERVICE THE GENERATOR. FOR ELECTRIC START SETS, DISCONNECT THE CRANKING BATTERY. FOR AIR START, DISCONNECT THE AIR SUPPLY. FOR MOTOR GENERATOR SETS, OPEN THE POWER SUPPLY TO THE DRIVE MOTOR. FAILURE TO COMPLY WITH THESE SAFETY PROCEDURES COULD RESULT IN SEVERE PERSONAL INJURY OR EQUIPMENT DAMAGE.

NEVER "BAR OVER" THE ENGINE GENERATOR SET USING THE GENERATOR'S FAN. THE FAN IS NOT DESIGNED FOR THIS PURPOSE. BARRING OVER THE SET WITH THE FAN COULD DAMAGE THE FAN AND RESULT IN PERSONAL INJURY OR EQUIPMENT DAMAGE.

GENERATOR MOUNTING

Single Bearing Units.

Single bearing units are provided with an SAE flywheel housing adapter flange and flexible drive discs. Coupling the generator's shaft to the engine flywheel is accomplished with special steel drive discs bolted to the shaft. In addition to the drive discs, there may be a hub spacer, spacer discs, or a combination of hub spacer and spacer discs inserted between the drive discs and the shaft to achieve the proper shaft extension ("G" dimension per SAE J620c). Holes are provided in the periphery of the coupling discs, which correspond to tapped holes in the prime mover's flywheel. The outside diameter of the drive discs fit in a rabbet in the flywheel so that concentricity is assured.

Grade 8 place bolts and hardened washers are recommended to mount the drive discs to the flywheel. DO NOT USE SPLIT TYPE LOCK WASHERS**.** Split lock washers when biting into the drive disc cause stress risers, which may result in the disc fracturing.

The SAE flywheel housing adapter ring and the engine flywheel housing are designed to match each other with no further alignment necessary. Use grade 5 or greater mounting bolts. MagnaPLUS generator frames are constructed with two or three boltholes per foot. The feet should be shimmed where necessary to obtain solid contact with the sub-base. With the frame securely bolted to the engine flywheel housing, there is no side thrust or pull on the generator frame, thus no real need to secure the feet with more than one bolt per foot.

GENERATOR MOUNTING

Two Bearing Generators -- Direct Drive

Two bearing generators are provided with a keyed shaft extension. For direct drive generators, the assembler furnishes a flexible coupling, which is installed between the driver and the generator's shaft. Aligning the generator and its driver as accurately as possible will reduce vibration, increases bearing life, and ensure minimum coupling wear. It may be necessary to shim the generator feet for proper support and alignment. Secure the feet of the generator with grade 5 or greater bolts through the holes provided in the mounting feet. Consult the coupling manufacturer's instructions for alignment specifications and procedures.

GENERATOR MOUNTING

Two Bearing Units -- Belt Driven

Two bearing MagnaPLUS generators can be belt driven provided belts are sized and applied correctly. Please refer to your supplier of belts and sheaves for correct sizing and tensioning specifications. A bearing life calculation should be performed. Katolight recommends a minimum B-10 life of 40,000 hours. If cog type belts are used, a vibration may be introduced which could lead to premature failure of the bearings.

END PLAY TESTING

Refer to the engine manual for recommended endplay specifications and measurement procedures. If endplay is not to specification, it is an indication that the generator shaft is not moving freely in the assembly, and normal life of the thrust bearing could be impaired. Probable causes of this problem are:

1. Improper seating of drive discs in the flywheel resulting in misalignment.

2. Improper mating of generator frame to engine flywheel housing resulting in misalignment.

3. Improper "G" dimension per SAE J620c on either the engine or generator.

TORSIONAL VIBRATION

Torsional vibrations are generated in all rotating shaft systems. In some cases, the amplitude of these vibrations at critical speeds may cause damage to the generator, its driver, or both. It is therefore necessary to examine the torsional vibration effect on the entire rotating system. IT IS THE RESPONSIBILITY OF THE GENERATOR SET ASSEMBLER TO ASSURE THE TORSIONAL COMPATIBILITY OF THE GENERATOR AND ITS DRIVER. Drawings showing pertinent dimensions and weights of the rotating assembly will be supplied by Katolight upon request.

ENVIRONMENTAL CONSIDERATIONS

The MagnaPLUS generator is designed for heavy-duty industrial applications; however, dirt, moisture, heat and vibrations are enemies of rotating electrical machinery. Excessive exposure to the elements may shorten generator life. The temperature of the cooling air entering the intake openings of the generator should not exceed the ambient temperature shown on the generator's nameplate. Generators intended for outdoor application should be protected with housings having adequate ventilation. Although the standard insulation systems are moisture and humidity resistant, space heaters are recommended for extreme conditions. If the generator is to be installed in an area where blowing sand and dust are present, the enclosure should be fitted with filters. Filters reduce erosion on the generator's insulation by blocking high velocity abrasive particles generated by the flow of cooling air through the generator. Consult the factory for appropriate filters and generator deratings required.

WIRING CONNECTIONS

Wiring of the generator and accessories should be done in accordance with good electrical practices. Follow government, industry and association standards.

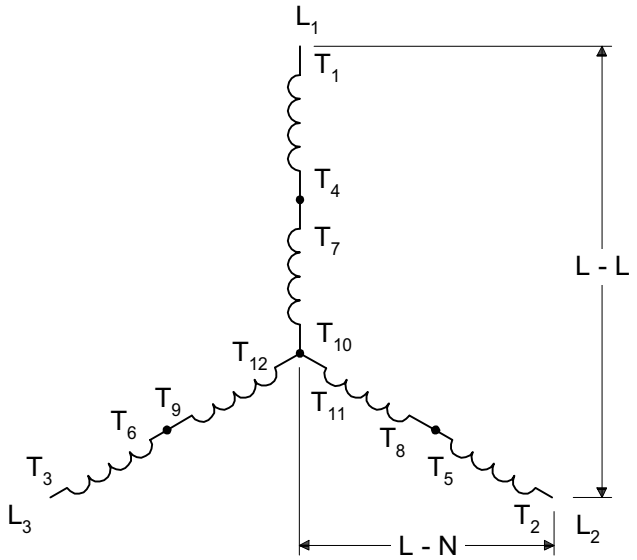
The generator conduit box construction allows cable entry from multiple sides. A hole saw or other appropriate tool may be used to provide for conduit entrance. Protect the interior of the generator from shavings when drilling or sawing. An approved connector must be used in conjunction with the conduit. To minimize the transmission of vibration, it is essential that flexible conduit be used for all electrical entrance to the generator conduit box.

All MagnaPLUS generators are equipped with link boards (terminal strips) for both internal and external connections. All connections made to the studs of the link board should be made with high quality ring terminals. Ring terminal sizes are 6 mm (280 Series Frames) and 10 mm (360 and 430 Series Frames). Torque link board connections to the following specifications: 280 frame -- 5.4 NM (4 Ft LB); 360 & 430 frame -- 27 NM (20 Ft LB).

Refer to the connection diagram supplied with the generator and / or the proper diagrams shown in this manual. Install all inter-component and external wiring in accordance with national and local electrical codes. The neutral in the following connection diagrams shown below may be either grounded (earthed) or left above ground potential (floating). See national and local codes and / or the system distribution wiring schematic diagram for the proper connection of the neutral.

The following connection diagrams are shown for twelve lead generators. Ten lead generators have the same terminal designations except for leads T10, T11, and T12. These three leads are internally connected inside the generator and brought out as a single lead (T0). Ten lead generators can only be connected in a wye configuration

HIGH WYE CONNECTION



VOLTAGE (HIGH WYE)		
Hz	L-L	L-N
60	480	277
	460	266
	440	254
	416	240

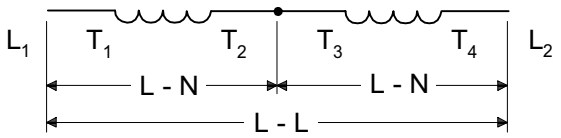
	460	220
50	415	208
	380	190

Note: Single-phase KW/KVA ratings are approximately equal to 50% of the generator's three phase ratings.

DEDICATED SINGLE PHASE CONNECTION



VOLTAGE (DEDICATED)		
Hz	L-L	L-N
60	240	120
	220	110
50	220	110
	200	100

OPERATION

PRE-START INSPECTION

Before starting the generator for the first time, the following inspection checks are recommended:

1. A visual inspection should be made for any loose parts, bad connections, or foreign materials.

2. Bar the set over by hand for at least 2 revolutions to be sure that there is no interference and that the set turns freely. If the set does not turn freely, check for clearance in the generator and exciter air gap.

3. Check all wiring against the proper connection diagrams, and ensure that all connections and terminations are tight and properly insulated.

WARNING

MAGNAPLUS GENERATORS MAY HAVE VOLTAGE PRESENT AT THE LEAD TERMINALS WHEN THE SHAFT IS ROTATING. DO NOT PERMIT OPERATION OF THE GENERATOR UNTIL ALL LEADS HAVE BEEN CONNECTED AND INSULATED. FAILURE TO DO THIS MAY RESULT IN PERSONAL INJURY OR EQUIPMENT DAMAGE

4. Verify that all equipment is properly grounded (earthed).

5. Clear the surrounding area of any materials that could be drawn into the generator.

6. Check all fasteners for tightness.

7. Check all access plates, covers, screens and guards. If they have been removed for assembly or inspection, reinstall and check for security.

8. Review all prime mover prestart-up instructions, and ensure that all recommended steps and procedures have been followed.

9. Remove any masking materials affixed during painting. Inspect the generator, prime mover, and any accessory equipment to ensure that nameplates, and all safety warning / caution signs and decals provided with the equipment are in place and clearly visible.

Note: It is strongly recommended that the authority having jurisdiction over the installation site be consulted to determine if any additional warning or caution notices, or additional safety devices are required by local codes / standards. Any such required notices or devices should be installed prior to initial startup.

START-UP

The following procedure should be followed when starting the generator set for the first time.

1. The generator output must be disconnected from the load. Be sure that the main circuit breaker or fused disconnect is in the open position.

2. Open the input power to the automatic voltage regulator. Remove the fuse or disconnect and insulate one of the regulator input power leads. (See separate regulator manual)

3. Verify that all prime mover start-up procedures have been followed.

4. If the unit is provided with space heaters, ensure that they are de-energized. In some installations, a set of auxiliary contacts on the main circuit breaker or transfer switch will automatically open the space heater circuit when the generator is connected to the load.

5. Start the prime mover, and adjust it for proper speed. See generator nameplate.

6. The purpose of this initial test with the regulator out of the circuit is to detect any wiring mistakes without exposing the unit to undue risk. Check all line to line and line to neutral voltages for balanced voltage. If voltages are balanced shut down the set and reconnect the regulator. If voltages are unbalanced, shut down the equipment and check for improper wiring. If the problem persists, consult the factory.

   With the regulator de-energized, the residual voltage should be 10 - 25% of rated value. It is recommended that this residual voltage and driver RPM be recorded for use as a future troubleshooting benchmark.

WARNING

QUALIFIED ELECTRICAL PERSONNEL MUST CONDUCT THE FOLLOWING TEST. LETHAL VOLTAGE MAY BE PRESENT AT BOTH THE GENERATOR AND VOLTAGE REGULATOR TERMINALS DURING THIS PROCEDURE. CAUTION MUST BE EXERCISED NOT TO COME INTO PERSONAL CONTACT WITH LIVE TERMINALS, LINKS, OR STUDS. SERIOUS INJURY OR DEATH COULD RESULT.

7. Start the set and adjust the terminal voltage to the desired value by means of the regulator voltage adjustment. If the regulator is equipped with a stability adjustment, follow the instructions in the regulator manual to adjust the stability. Again, check all line to line and line to neutral voltages for balance. It is recommended practice to record the no load excitation (DC voltage to the exciter stator), generator terminal voltage, and driver speed as a benchmark for future troubleshooting.

8. Close the main circuit breaker to the load.

9. Monitor the generator output current to verify that it is at or below nameplate value.

10. Check generator speed (frequency) under load. Adjust as necessary. (Refer to prime mover or governor manuals)

SHUTDOWN PROCEDURE

There are no specific instructions for shutting down the generator; however, several good practices should be observed to prolong equipment life.

1. It is advisable to disconnect all loads (open main circuit breaker or disconnect) prior to shutdown. This is especially important if loads can be damaged by low voltage or low frequency conditions during generator "coast down".

2. Isolate all conditions that could apply voltage to the generator terminals while the generator is at rest. Failure to comply could result in personnel injury or equipment damage.

3. If the unit is equipped with space heaters, verify that the heater circuit is energized.

MAINTENANCE

The following maintenance procedures should be followed to ensure long equipment life and satisfactory performance. Maintenance intervals will depend upon operating conditions.

1. Routinely check intake and exhaust air screens to ensure that they are clean and free of debris. Clogged intake air screens will reduce cooling airflow and result in higher operating temperatures. This will reduce generator life and may result in generator damage.

2. All MagnaPLUS generators are equipped with double shielded ball bearings lubricated for the life of the bearing. Every 1,000 hours check the bearing(s) for smooth, quiet operation. For continuous duty generators, recommended practice is to replace the bearing during major overhauls of the engine.

3. Periodically inspect the unit for any buildup of contamination (dirt, oil, etc.) on the windings. If the wound components have become coated with heavy concentrations of oil and grime, the unit should be disassembled and thoroughly cleaned. This operation is not one that can be accomplished effectively on site, but rather one that should be conducted by an authorized service center equipped with the appropriate apparatus and solvents necessary to properly clean and dry the generator.

WARNING

QUALIFIED ELECTRICAL PERSONNEL MUST CONDUCT THE FOLLOWING TEST. LETHAL VOLTAGE MAY BE PRESENT AT BOTH THE GENERATOR AND VOLTAGE REGULATOR TERMINALS DURING THIS PROCEDURE. CAUTION MUST BE EXERCISED NOT TO COME INTO PERSONAL CONTACT WITH LIVE TERMINALS, LINKS, OR STUDS. SERIOUS INJURY OR DEATH COULD RESULT.

4. Every 2,000 operating hours or in conjunction with scheduled engine maintenance check the DC no load excitation voltage per item #7 in the startup procedure. Compare this voltage with the value recorded during initial startup. If this value of no load excitation voltage is markedly higher than the benchmark reading, it is an indication of problems in the exciter, main field, or the rotating rectifier assembly. Ensure that RPM is the same as initial test.

5. Monitor and record insulation resistance with a 500 volt mega-ohm meter. The minimum acceptable reading is 2 mega-ohms. If the reading drops below the minimum, the generator should be cleaned and dried at an authorized service shop. Consult Katolight for more information.

DRYING WINDINGS

Generators in service may inadvertently have their windings exposed to splashing or sprayed water. Units that have been in transit or storage for long periods of time may be subjected to extreme temperature and moisture changes causing excessive condensation. Regardless of the source of moisture, wet windings should be thoroughly dried out before operating the unit. If this precaution is not taken, serious damage to the generator can result. The following procedures may be utilized in drying the generator's windings. Winding wetness and situation limitations will influence the method selected.

Space Heaters

An electric heater may have been supplied with the generator. When energized from a power source other than the generator, the heater will gradually dry the generator. Enclosing the unit with covering and inserting additional heating units can accelerate this process. A hole should be left at the top of the covering to permit the escape of moisture. Care should be taken not to overheat various accessory equipment mounted with the generator.

Forced Air

Another method to dry the generator is to run the set with no excitation (see startup procedure item #2). The natural flow of ambient air through the generator will tend to dry the windings. This method can be accelerated by adding a source of heat at the air intake to the generator. Heat at point of entry should not exceed 80 C (180 F).

TESTING

Visual Inspection

Remove covers and look for any obvious problems: burnt windings, loose connections, broken wires, frayed insulation, cracked brackets, missing hardware, etc. Check for foreign objects that may have been drawn into the generator. Verify that the generator's air gaps (main rotor and exciter) are free from obstructions. If possible, rotate the generator manually to ensure free rotation. Never "bar over" the engine generator set using the generator fan.

WARNING

QUALIFIED ELECTRICAL PERSONNEL MUST CONDUCT THE FOLLOWING TEST. LETHAL VOLTAGE MAY BE PRESENT AT BOTH THE GENERATOR AND VOLTAGE REGULATOR TERMINALS DURING THIS PROCEDURE. CAUTION MUST BE EXERCISED NOT TO COME INTO PERSONAL CONTACT WITH LIVE TERMINALS, LINKS, OR STUDS. SERIOUS INJURY OR DEATH COULD RESULT.

Constant Excitation Test
(12V BATTERY TEST)

The generator "no load" voltage is dependent on exciter input voltage and generator speed. With the generator operating at rated speed and 12 volts dc applied to the exciter field, the generators terminal voltage will be near rated value.

1. Shutdown the generator set and connect a voltmeter on the generator terminals.

2. Disconnect the regulator's F+ (F1) and F- (F2) leads and connect them to a 12V battery. Caution should be taken to ensure that the battery is not exposed to any potential arcing.

3. With no load on the generator (main breaker open) run the generator at rated speed. Measure the generator's terminal voltage and compare this value with values recorded during installation.

If voltage readings are normal, the main generator and excitation are operating properly. Troubleshooting should continue with the regulator. If readings are not normal the problem is in the generator. Continue testing diodes, surge suppressor, and windings.

Continuity / Resistance Test

The generator has four components that can be checked using an ohmmeter: exciter stator, exciter rotor, main stator and main rotor. Each of these components is comprised of various windings that form a complete electrical path of relatively low resistance. Using an ohm meter measure the loop resistance of each component. Compare these measured values with the values listed in the specification section of this manual. Note that very small resistance values require precision equipment to make accurate measurements; however, a standard ohmmeter will provide a good indication of winding continuity.

Insulation Test

Insulation resistance is a measure of the integrity of the insulating materials that separate the electrical windings from the generator's steel core. This resistance can degrade over time or be degraded by contaminants: dust, dirt, oil, grease, and especially moisture. Most winding failures are due to a breakdown in the insulation system. In many cases, low insulation resistance is caused by moisture collected when the generator is shutdown

Insulation resistance is measured with a megger (mega-ohm meter). A megger measures insulation resistance by placing 500 volts between the winding and the frame of the generator. Caution must be taken to remove all electronic devices (regulators, diodes, surge protectors, capacitors, protective relays, etc.) from the winding circuit before checking the insulation. Winding insulation can be checked on the main stator, main rotor, exciter stator, and exciter rotor. Minimum resistance is 2 mega-ohms. If the winding resistance is low it must be dried (see maintenance section) or repaired.

DIODE TESTING

If the generator is close coupled to an engine, it may be necessary to "bar over" the engine in order to gain access to a given area of the rectifier assembly. **NEVER** use the generator's fan as a fulcrum to accomplish this. Use the engine manufacturer's recommended practice to manually turn over the engine. To prevent possible injury to personnel, and damage to the equipment, ensure that the engine cannot start during this procedure.

Remove the two main rotor leads and the three exciter rotor leads from the rectifier assembly (figure 4). The rectifier assembly is now electrically isolated from the generator. The diodes remain mounted and the diode leads remain connected to the terminal posts. Using an ohmmeter or a battery light continuity tester, place one test probe on the diode lead terminal post. In succession, touch the other test probe to the lead screw hole in each heat sink. Reverse the probes and repeat the procedure. You have now tested the three diodes connected to this terminal post in both the forward and reverse direction. Repeat the procedure using the other diode terminal post.

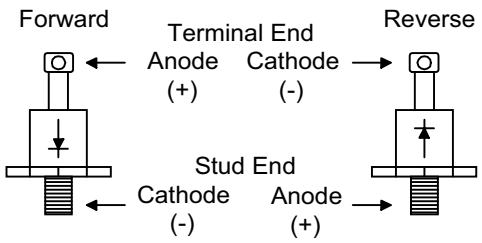


FIGURE 3: DIODE POLARITY

When the positive test probe is connected to the diode's anode and the negative test probe is connected to the diode's cathode (forward biased), the diode will switch on and conduct electricity (figure 3). This is observed by a low resistance reading when using an ohm meter or the lighting of the bulb when using a battery light continuity tester. Reversing the test leads (reverse biased) will result in the diode switching off and no electricity will be conducted. The results of these tests should indicate one of three conditions:

1. **Good diode:** Will have a much greater resistance in one direction than the other. Typical reverse biased resistance will be 30,000 ohms or greater, while forward biased resistance will be less than 10 ohms. The battery-light tester will have the light "on" in one direction and "off" in the other.

2. **Shorted condition:** Ohmmeter reading will be zero, or very low in both directions. The continuity tester will have the light "on" in both directions.

3. **Open condition:** Ohmmeter will have a maximum (infinity) reading in both directions. Continuity tester light will be off in both directions.

Diode failure after a 25 hour "run-in" period is generally traceable to external causes such as a lightning strike, reverse current, line voltage spikes, etc. All 6 diodes are essentially in the same circuit. When a diode is stressed to failure, there is no easy method to determine remaining life in the other diodes. To avoid possible continued failures, it is recommended that the entire rectifier assembly be replaced rather than replacing individual diodes.

SERVICE

GENERAL

The service procedures given in this section are those which can reasonably be conducted on-site with a minimum number of special tools and equipment. Qualified maintenance personnel should conduct all service procedures. Replacement parts may be ordered through an authorized service center or directly from the factory**.**

FIELD FLASHING

Restoring Residual Magnetism
(not applicable on PMG equipped generators)

To restore residual magnetism to the generator, connect a 12 volt battery to the exciter field while the generator using the following procedure:

1. Shutdown the generator set. Remove the exciter field leads F+ and F- from the regulator.

CAUTION:
Failure to remove the exciter field leads from the automatic voltage regulator during flashing procedures may destroy the regulator.

2. Connect the F+ and F- leads to the battery's corresponding positive and negative terminals. This should be done using an appropriate length of lead wire to separate the battery from the point of connection (batteries may explode when exposed to an electric arc). After 3 to 5 seconds, remove the F- lead. An inductive arc should result. If no arc is drawn, repeat the procedure.

3. Reconnect the F+ and F- leads to the regulator. Restart the generator and verify that terminal voltage is developed. If terminal voltage does not develop, repeat the field flashing procedure and / or consult the trouble shooting section.

Bearing Removal

Prior to performing this operation, it is suggested that the alternator's shaft be rotated until two of the main rotor poles are in a vertical position. Once the bearing bracket is backed out, the rotor will drop on the main stator core. Having the rotor in this position will limit the amount of rotor drop to that of the air gap. Visually inspect the bearing bore for damage or wear. If worn or damaged, replace prior to reassemble.

Opposite Drive End Bearing Bracket Removal.
Prior to proceeding with bracket removal, disconnect exciter field leads F+ and F- from the automatic voltage regulator and ensure that they are free to move when the bearing bracket is removed. Remove the bearing bracket retaining bolts. Using a pair of screw drivers, wedge the bracket off the frame. After approximately 1/8 inch, the bracket will clear the locating register on the frame and will drop until the rotor is resting on the main stator core. Continue to pull the bracket free from the bearing. Visually inspect the bearing bore and o-ring (if equipped) for damage or wear. If worn or damaged, repair or replace prior to reassembly.

Drive End Bearing Bracket Removal,
Two Bearing Units.
Remove any drive arrangement from the generator shaft extension. Remove the bearing lock ring retaining screws. There is no o-ring in the drive end bearing bracket. The shaft extension must be supported before proceeding further. A hoist and sling, jack, or some other means of support with a capacity of 2 tons should be used.

Remove the bearing bracket retaining cap screws. Using a flat bladed screw driver or chisel, pry the bracket back from the frame. After approximately 1/8 inch, the bracket will clear the locating register on the frame. Lower the shaft extension until the rotor is resting on the main stator core. Continue to pull the bracket free from the bearing. Visually inspect the bearing bore for damage or wear. If worn or damaged, sleeve or replace prior to reassembly.

Reassembly note: Before the bearing bracket is seated against the frame, a threaded rod may be used to help align the inner bearing cap with the bearing bracket.

BEARING REPLACEMENT

Using a bearing puller, remove the existing bearing. It is strongly recommended that the bearing be replaced any time it is removed from the shaft. **ALWAYS** install the same type and size bearing that was supplied as original equipment. Order by part number from the parts list, and include the unit serial number and part number when ordering. Heat the bearing to a maximum of 100°C (212°F) in an oven. Apply a thin coat of clean lubricating oil to the press-fit area of the rotor shaft. Using suitable heat resistant gloves, install the bearing over the end of the shaft until it seats against the shaft shoulder. The bearing should slide on the shaft and be seated without excessive force. Should the bearing bind on the shaft prior to being seated against the shoulder, a piece of tubing slightly larger than the press fit area can be used to drive the bearing to its final position. Using light taps with a soft mallet, apply pressure to the inner race only.

Rectifier Assembly Removal

The rectifier assembly cannot be removed until the opposite drive end bearing bracket and bearing have been removed (see bearing removal procedure). Remove the three exciter rotor leads from the heat sinks and the two main rotor leads from the main rotor posts (see Figures 4). Remove the screws securing the rectifier assembly and pull the assembly free from the shaft.

Diode Replacement

Prior to installing a replacement diode on the heat sink, apply a thin film of conductive heat sink compound around the base of the diode (do not coat the threads). When installing a diode on the heat sink, care should be taken not to over torque the retaining nut, which could cause damage to the device. Torque to 28 pound-inches. If not damaged, the existing diode lead wire may be unsoldered from the failed diode, and resoldered on the replacement.

RETURNED GOODS

Contact Katolight Corporation for authorization before returning any product. We can not be responsible for any items returned without authorization.

CAUTION

Single bearing generators must have their rotor assembly properly secured to prevent damage during transit to the factory, or to an authorized service center.

TROUBLESHOOTING

This section is intended to suggest a systematic approach to locating and correcting generator malfunctions. The section is arranged according to the symptoms of the problem. The steps have been arranged in an attempt to do the easy checks first and prevent further damage when troubleshooting a disabled machine.

The first step of troubleshooting is to gather as much information as is possible from operating personnel and individuals present during the failure. Typical information includes: how long the unit had been operating; what loads were on line; weather conditions; protective equipment that did or did not function. In addition, information as to the operating condition of the generator's prime mover is vital. Has the prime mover been maintaining constant speed? If not, have there been extended periods of under speed operation? Has the prime mover experienced an over-speed condition? If yes, what was the maximum speed, and how long did the unit operate at that elevated speed?

The generator speed should be maintained at rated nameplate value during all operating tests. The frequency of the generator depends upon rotational speed. Most regulators used with MagnaPLUS generators have built in under frequency protection such that if the speed is reduced more than 5%, the voltage will drop off rather rapidly with further reductions in speed.

WARNING

HIGH VOLTAGES MAY BE PRESENT AT THE GENERATOR'S TERMINALS WHEN THE UNIT IS RUNNING. SOME ACCESSORY EQUIPMENT SUCH AS SPACE HEATERS MAY BE ENERGIZED FROM AN OUTSIDE POWER SOURCE WHEN THE UNIT IS AT REST. TOOLS, EQUIPMENT, CLOTHING AND YOUR BODY MUST BE KEPT CLEAR OF ROTATING PARTS AND ELECTRICAL CONNECTIONS. SPECIAL PRECAUTIONS MUST BE TAKEN DURING TROUBLESHOOTING SINCE PROTECTIVE COVERS AND SAFETY DEVICES MAY BE REMOVED OR DISABLED TO GAIN ACCESS AND PERFORM TESTS. BE CAREFUL. SERIOUS PERSONAL INJURY OR DEATH CAN RESULT FROM THESE HAZARDS. CONSULT QUALIFIED PERSONNEL WITH ANY QUESTIONS.

GENERATOR PRODUCES NO VOLTAGE

CAUSE	CHECK AND REMEDY
Voltmeter off or defective	Check voltage with a separate meter at the generator terminals.
Incorrect or defective connections	Verify generator connections. See drawings supplied with the generator or lead connection diagrams in this manual. Inspect all wiring for loose connections, open circuits, grounds, and short circuits.
Loss of residual	Flash the field. Refer to field flashing in the service section. If the generator is equipped with a PMG, field flashing is not necessary -- check regulator fuse and input power from the PMG.
Defective diodes, suppressor, or windings	Test the generator using the 12 volt battery test as specified in the testing section. If the results indicate generator problems, perform insulation, continuity, and diode tests as specified in the testing section.
Regulator protection operating	Adjust regulator. Consult regulator manual.
Regulator inoperative	Adjust or replace regulator. Consult regulator manual.

GENERATOR PRODUCES LOW VOLTAGE, NO LOAD

CAUSE	CHECK AND REMEDY
Underspeed operation	Check speed using a tachometer or frequency meter.
Voltmeter off or defective	Check voltage with a separate meter at the generator terminals.
Incorrect or defective connections	Verify generator connections. See drawings supplied with the generator or lead connection diagrams in this manual. Inspect all wiring for grounds, open circuits and short circuits.
Loss of regulator power	Check regulator fuse and input power. Input power is produced by the generator's residual voltage or from an optional PMG.
Regulator adjustment	Adjust regulator settings. Consult regulator manual.
Regulator incorrectly connected	Review the generator connection diagram or reference the regulator manual.
Defective diodes, suppressor, or windings	Test the generator using the 12 volt battery test as specified in the testing section. If the results indicate generator problems, perform insulation, continuity, and diode tests as specified in the testing section.
Regulator inoperative	Adjust or replace regulator. Consult regulator manual.

GENERATOR PRODUCES LOW VOLTAGE WHEN LOAD APPLIED

CAUSE	CHECK AND REMEDY
Excessive load	Reduce load. The load on each leg should be evenly balanced, and rated current should not be exceeded on any leg.
Large motor starting or low load power factor	Motor starting currents are too large for the generator. When starting multiple motors, sequence the motors and start the largest motors first. Reduce lagging power factor load.
Driver speed droop or belt slip	Check driver. If belt driven, check belt tension. Check under frequency setting on regulator. Under frequency voltage roll-off may be activated.
Reactive droop	If the generator is equipped for parallel operation, some droop is normal as reactive load increases. When operating as a single unit, the parallel CT can be shorted to eliminate this effect. Refer to Regulator manual.
Line drop	If voltage is proper at generator terminals but low at load terminals, increase external wire size.
Defective diodes, suppressor, or windings	Test the generator using the 12 volt battery test as specified in the testing section. If the results indicate generator problems, perform insulation, continuity, and diode tests as specified in the testing section.

GENERATOR PRODUCES FLUCTUATING VOLTAGE

CAUSE	CHECK AND REMEDY
Fluctuating engine speed	Check engine and governor systems for malfunctions. Check load for fluctuation.
Regulator stability	Adjust Regulator stability. Refer to Regulator manual.
Regulator external rheostat	Replace defective or worn rheostat. Use shielded cable to minimize electrical noise.
Defective rectifier assembly	Check assembly for loose connections. Test the diodes as specified in the test section.
Loose terminal or load connections	Improve connections both mechanically and electrically.
Defective regulator	Replace regulator.

GENERATOR PRODUCES HIGH VOLTAGE

CAUSE	CHECK AND REMEDY
Faulty metering	Check voltage with separate meter at generator terminals.
Incorrect connections	Verify generator connections. Refer to drawings supplied with the generator or connection diagrams in this manual.
Regulator adjustments	Adjust regulator. Consult regulator manual.
Leading power factor	Check the power factor of the load. If power factor is leading, change load configuration. Excessive leading power factor (capacitors) can cause voltage to climb out of control.
Incorrect regulator connection	Verify regulator voltage sensing is connected correctly. Consult regulator manual.
Defective regulator	Replace regulator.

GENERATOR BUILDS VOLTAGE FROM STARTUP, THEN GOES TO LOW (RESIDUAL) VOLTAGE

CAUSE	CHECK AND REMEDY
Regulator protective circuit operating	Check indicators on regulator. Correct problems and adjust regulator as is required. Refer to regulator manual.

GENERATOR IS OVERHEATING

CAUSE	CHECK AND REMEDY
Generator is overloaded	Reduce load. Check with ammeter and compare with nameplate rating.
Clogged ventilating screens	Clean air passages.
High room temperature or altitude	Improve ventilation or reduce load.
Insufficient circulation of cooling air	Generator location and enclosure design must provide adequate airflow and minimize recirculation of hot air.
Unbalanced load	The load on each leg should be as evenly balanced as possible and should not exceed rated current on any one leg.

GENERATOR PRODUCES MECHANICAL NOISE

CAUSE	CHECK AND REMEDY
Defective bearing	Replace bearing.
Loose or misaligned coupling	Tighten, realign, or replace coupling.
Belt slap or loose guards	Check belt tensioning. Check belt guard fasteners.

EQUIPMENT RUNS NORMALLY ON UTILITY POWER, BUT WILL NOT RUN ON GENERATOR

CAUSE	CHECK AND REMEDY
Distorted voltage waveform	Analyze load. Excessive SCR (thyristor) loading will cause distortion. Some equipment may be sensitive to distorted waveforms. Refer to Katolight.
Improper generator voltage or frequency	Check nameplates of devices comprising the load. Compare required voltage and frequency with that of the generator. Adjust driver speed and/or generator voltage as necessary to match generator output to load requirements.

CAUTION: Compare required voltage, frequency, and kVA with generator nameplate to ensure adequate generator capacity. If in doubt, consult Katolight for information regarding generator capacity.

SPECIFICATIONS

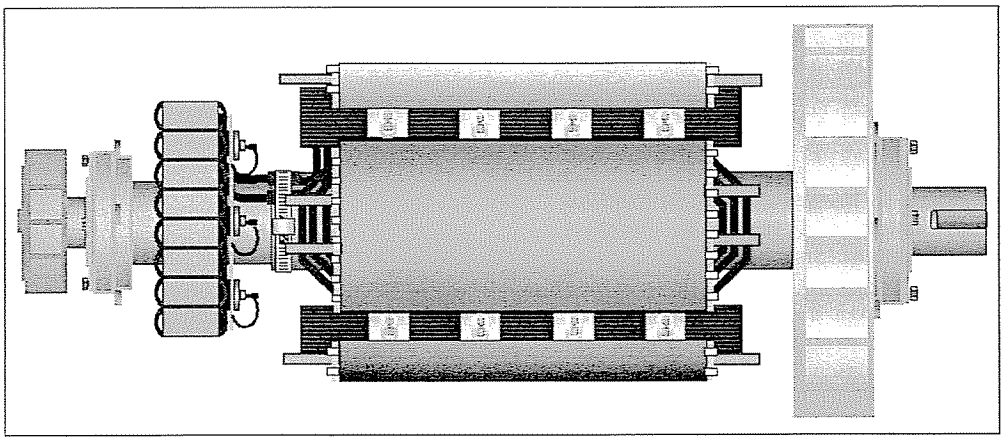
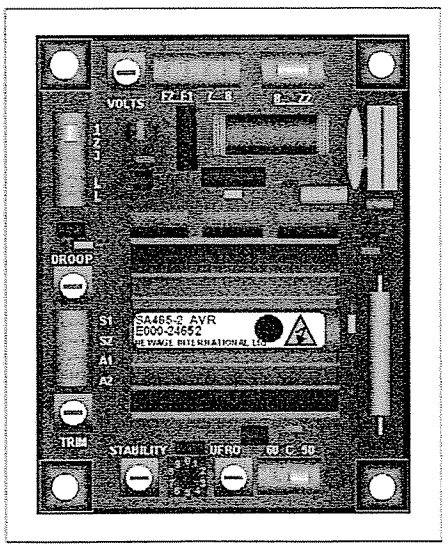
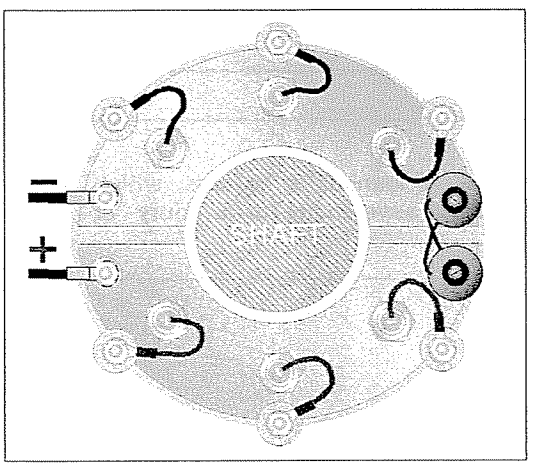
FAULT FINDING MANUAL

For Self Excited and Separately Excited Generators







SAFETY PRECAUTIONS

Before testing the generating set, read the generating set Installation Manual, and this Fault Finding Manual, and become familiar with it and the equipment.

SAFE AND EFFICIENT OPERATION CAN ONLY BE ACHIEVED IF THE EQUIPMENT IS CORRECTLY INSTALLED, OPERATED AND MAINTAINED.

Many accidents occur because of a failure to follow fundamental rules and precautions.

ELECTRICAL SHOCK CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

- Ensure installation meets all applicable safety and local electrical codes. Have all installations performed by qualified Installation technicians.
- Do not operate the generator with protective covers, access covers or terminal box covers removed.
- Disable engine starting circuits before carrying out maintenance.
- Disable closing circuits and/or place warning notices on any circuit breakers normally used for connection to the mains or other generators, to avoid accidental closure.

Observe all IMPORTANT, CAUTION, WARNING, and DANGER notices, defined as:

Important ! Important refers to hazard or unsafe method or practice, which can result in product damage or related equipment damage.

Caution ! Caution refers to hazard or unsafe method or practice, which can result in product damage or personal injury.

Warning !

Warning refers to a hazard or unsafe method or practice, which CAN result in severe personal injury or possible death.

Danger !

Danger refers to immediate hazards, which WILL result in severe personal injury or death.

TESTING "LIVE" EQUIPMENT

It is essential that all test instruments are regularly checked for safety, and any connection leads, probes, or clips, are checked to ensure that they are suitable for the voltage levels being tested.

Danger !

Never attempt to test a "LIVE" generator unless there is another competent person present who can switch off the power supply or shut down the engine in an emergency.

Never expose "LIVE" connections unless you have created a safe working area around you. Make sure you have made all other persons in the immediate area fully aware of what you are doing.

Due to our policy of continuous improvement, details in this manual which were correct at time of printing, may now be due for amendment. Information included must therefore not be regarded as binding.

SECTION 4
Fault Finding method 'B', for Self-Excited Generators.
Automatic Voltage Regulator is powered from the Generator Output.

SECTION 5
Fault Finding method 'B', for Separately Excited Generators
Automatic Voltage Regulator is powered from the Permanent Magnet Generator.

SECTION 6
Parallel Operation and Fault Finding for All Generators

SECTION 1

RECOMMENDED METERING AND TEST INSTRUMENTS

To successfully carry out the various test procedures suggested in this manual, certain test instruments are essential. The following lists detail the basic requirements in this respect.

It should be noted that in addition to these instruments a comprehensive kit of tools is also essential. For fault finding purposes this need not include any specialised tools.

Item 1 - Multimeter

The Multimeter is a comprehensive test instrument for measuring voltage, current and resistance. It should be capable of measuring the following ranges:-

Voltage A C	0-250-500-1000 Volts
Voltage D C	0-25-100-250 Volts
Amperes D C	0-10 Amps
D C Resistance	0-10k (ohms) or 0-2k (ohms)
	0-100k (ohms) or 0-20k (ohms)
	0-1M (ohms) or 0-200k (ohms)

Item 2 – Tachometer or Frequency meter

This instrument is for measuring the shaft speed of the alternator and should be capable of measuring speeds between 0 and 5000 revolutions per minute, (RPM).

An alternative to the tachometer is the frequency meter (see Section 2 on Frequency and Speed, for details). However the alternator must be generating its normal output voltage for this instrument to be accurate.

Item 3 – Megger (Insulation test meter)

This instrument generates a voltage of 500V or 1000V, and is used to measure the resistance value of the insulation to earth (ground). It may be an electronic push button type, or a hand cranked generator type.

Item 4 - Clip-On Ammeter (Clampmeter)

Used to measure A C current, it consists of a pair of callipers, which are clamped around the conductor, and by means of a transformer action, gives an indication of the amperes flowing in the conductor. Useful ranges to have on this meter are:-

A C Amps 0-10-50-100-250-500-1000

Item 5 – Kelvin Bridge – low resistance meter

This instrument is used to measure resistance values below 1.0 ohm. They are bulky, and expensive, but are the only means of accurately measuring very low resistances, such as main stator and exciter rotor windings.
However, there are other methods of testing low resistance windings, and these are included in the various test procedures, i.e. Test Method A (Section 3). This section will enable the main generator windings to be tested while running the generator at normal speed without load.

It is essential that all test instruments be regularly checked for safety, and any connection leads, probes or clips checked to ensure that they are suitable for the voltage levels being tested.

Never attempt to test a "LIVE" generator unless there is another competent person present who can switch off the power supply or shut down the engine in an emergency.

Never expose "LIVE" connections unless you have created a safe working area around you. Make sure you have made all other persons in the immediate area fully aware of what you are doing.

MEDIUM/HIGH VOLTAGE
3.3 kVA to 11.0 kVA

Do not attempt to carry out tests on medium or high voltage generators without using specialised instruments and probes, with suitable protection equipment and procedures for grounding (earthing) the output terminals.

SECTION 2

ELECTRICAL TERMINOLOGY AND RESISTANCES
VOLTAGE AND CURRENT (AMPERES)

An AC Generator is designed to produce a voltage level suitable for the load to which it is connected. The control circuits are designed to automatically maintain this voltage level as the load is increased or decreased.

Sudden large changes in loading will produce temporary changes in the voltage. The control circuit is designed to recover to a stable condition as quickly as possible.
The current drawn from the AC Generator is determined by the amount of load connected to it. Current creates a temperature rise in the windings, hence the requirement for drawing air through the AC Generator by means of the fan. If the full load rated current is exceeded on any phase of the main stator windings, it will result in overheating in this winding. Similarly, any restriction in the flow of air through the machine will result in a rapid increase in the temperature of the windings.

Frequency (Hz) and Speed (RPM)

An AC Generator is a constant speed device, and should not be operated at speeds above 4% of the rated speed, or more than 1% below the rated speed.

Load changes will create temporary changes in the speed, but the engine must be capable of returning to the steady state condition within a few seconds.

The speed requirements for the AC Generator are determined by:-

(a) The frequency (Hz) requirement of the load
(b) The number of poles,(main rotor coils), in the generator

$$\text{Frequency (HZ)} = \frac{\text{N (speed) X P (pairs of poles)}}{\text{60 (sec's)}}$$

This can be shown more clearly in a chart: -

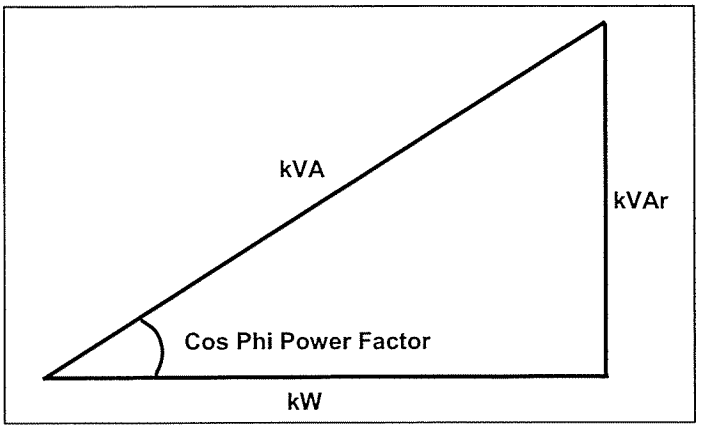
Frequency (Hz)	Speed (R.P.M.)	No. of Poles (rotor coils)
50	1500	4
60	1800	4
50	1000	6
60	1200	6
50	3000	2
60	3600	2

From this chart, a simple formula is produced to calculate the speed from the frequency, or vice versa.

4 pole machine 1 cycle (Hz) = 30 R.P.M.
6 pole machine 1 cycle (Hz) = 20 R.P.M.
2 pole machine 1 cycle (Hz) = 60 R.P.M.

Kilowatts (kW) kilo Volt Amperes (kVA) and Power Factors (pf.)

For an AC Generator to supply power for a load of 1kW, the prime mover (engine) driving the alternator must produce approximately 1.5 horsepower.



Kilowatts are calculated by the formula: -

$$kW = \frac{\text{Volts x Amperes x Power Factor}}{1000}$$

kVA (kilo Volt Amperes), are calculated by the formula:-

$$kVA = \frac{\text{Volts x Amperes}}{1000}$$

Both equations are multiplied by $\sqrt{3}$ (1.732) for a 3 phase machine.

Power Factor

The Power Factor (pf), is a measure of wasted current, which is a product of inductive loads such as motors, transformers, (magnetic circuits), and some forms of lighting.

The formula for calculating the Power Factor is:-

$$pf = \frac{\text{kilowatts}}{\text{kVA}}$$

Unity Power Factor (pf 1)

Purely resistive load, i.e. heating, tungsten filament lighting, has a power factor of one, (pf 1), and contains very little Wattless (inductive) load, which is power factor zero, (pf 0).
An AC Generator will deliver continuously the rated full load current at any power factor between pf 1 (unity) and 0.8. However, the prime mover, (engine), is greatly affected by the power factor. At pf 1, the kVA and kW are equal; therefore the engine is supplying 20% more kW load at pf 1, than it is at pf 0.8. It is important, therefore, that this is taken into consideration, when approaching 75% to 100% load current of the Generator, with a power factor higher than 0.8.

Lagging Power Factors

A Generator is designed to deliver the full load current at any power factor between unity and 0.8 lagging. Certain loads have a power factor lower than 0,8 lag, e.g. welding transformers; autotransformer, start motors, gas discharge lighting. A reduction in the full load (kVA), rating is required for a lagging pf lower than 0.8.

Leading Power Factors

Capacitive load e.g. some fluorescent lighting, power factor correction capacitor banks, produce leading power factor current. The latter is required by the Electricity authorities to improve the customers lagging power factor. The capacitor bank size is measured in kVAr (reactive).

A purely Capacitive load can cause the Generator control system, (AVR), to loose control, creating voltage instability, and possible high voltage from the Generator.
This is due to the fact that, unlike most loads, which are pf 1, (unity) or lagging pf, a leading pf load current will cause the Generator excitation voltage to decrease, as the load current increases.
Eventually the control system will be unable to control the Generator excitation level, and voltage instability will occur.
The degree of instability is determined by the kVAr size of the capacitors, relative to the kVA size of the alternator.

Capacitive load can present a problem for mains failure (standby) Generators. When the mains electricity supply fails, all motor, (inductive), load is disconnected by the individual contactors. Subsequently, when the Generator is connected to the system, the load will mainly consist of lighting, and possibly the power factor correction capacitors. In this situation the AC Generator will see a very low, (leading), power factor, and may become unstable, and/or generate high voltage.

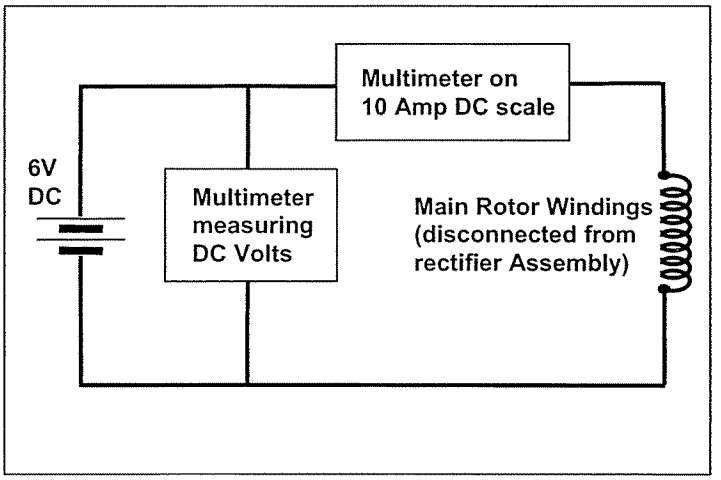
In order to prevent this situation, it is advisable to ensure that the power factor correction capacitors are switched OFF when the generator takes the initial load.

Further advice in this respect may be obtained from Newage–AVK SEG if required.

Resistances - measuring component values

When fault finding it is necessary to measure the resistance values of components and windings, and compare them with known normal values, in order to identify a faulty winding. The normal resistances of the windings are given in the winding resistance charts, in the generator installation and maintenance handbooks, service and maintenance section.

Resistance values above 10 ohms can be measured accurately with a multimeter. Between 0.5 and 5 ohms a multimeter has a limited accuracy, and other test methods may be adopted.



Resistances between 0.5 And 5 Ohms

The resistance value of a winding such as a brushless main rotor will be between 0.5 and 3 ohms. A multimeter may not give an accurate enough reading at these levels. If a Wheatstone Bridge Resistance Meter is not available, an accurate measurement can be obtained by means of a battery supply, using a Multimeter in series on the 10 Amps D.C. range. Most Multimeters have this current range, or alternatively, a battery charging Ammeter could be used instead).

Using 6 volt battery cells the resistance of the winding can be calculated i.e.

$$\frac{\text{V (volts)}}{\text{I (amps)}} = \text{ohms (resistance)}$$

The resultant can be compared with the correct value given in the resistance charts, and this method can be used for any resistance greater than 0.5 ohm.

Below this value the current in the circuit would drain the battery, and it is therefore impractical to use this method.

Very low resistance values (below 0.5 ohm)

Main stators and exciter rotors are included in this category.

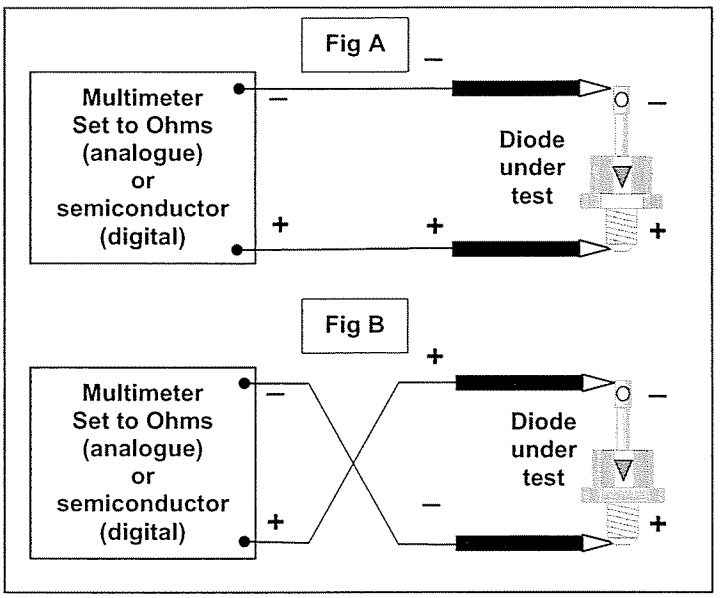
These values can only be measured accurately with a special instrument, such as a Kelvin bridge test meter.
The test leads are equipped with special spiked probes, which penetrate the surface of the contact, ensuring accurate reading.

The generators main stator windings can also be tested by means of separately exciting the machine (see, Section 3, Test Method A), thus partly eliminating the need to have this specialised type of instrument when fault finding in the field.

Diode Testing

A Diode has two resistance values, forward and reverse,
These can be measured with a multimeter as shown in the diagram below.
An arrow printed on the diode body identifies the positive side of a diode.

The forward resistance is being measured in Fig. A with the positive meter lead connected to the forward side of the diode.
In Figure 'B' the meter leads have been reversed, and the reverse resistance is being measured.



An electronic digital instrument will read true electron flow, hence the resistance polarity readings will be reverse to conventional current flow, i.e. forward and reverse readings will be reversed.
A Digital Multimeter usually has a semiconductor test scale on the selector switch, marked as shown :-

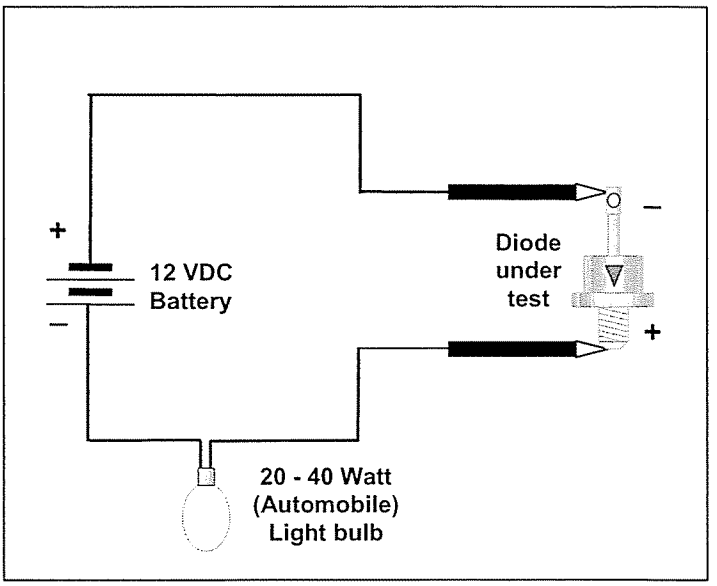
This measures true electron flow, and will give a forward, (indication reading only), or reverse (no reading) indication.

Using an analogue meter on resistance scale, the forward resistance varies considerably, depending on the internal impedance of the Multimeter, and the diode type.
A typical reading would be between 20 and 100 ohms.

The reverse resistance must be very much higher, usually in excess of 100k ohms, (100,000 ohms).

A faulty diode will give a reading in both forward and reverse directions (short circuit), or no reading in either direction, (open circuit).

Simple Alternative Diode Test Circuit



A good diode will light the bulb in only one direction. It should not light when test leads are reversed on the diode pin and base.

A faulty diode will light the bulb in both forward and reverse directions (short circuit diode), or no light in either direction, (open circuit diode).

If one or more diodes are found to be faulty, always change the complete set of diodes.

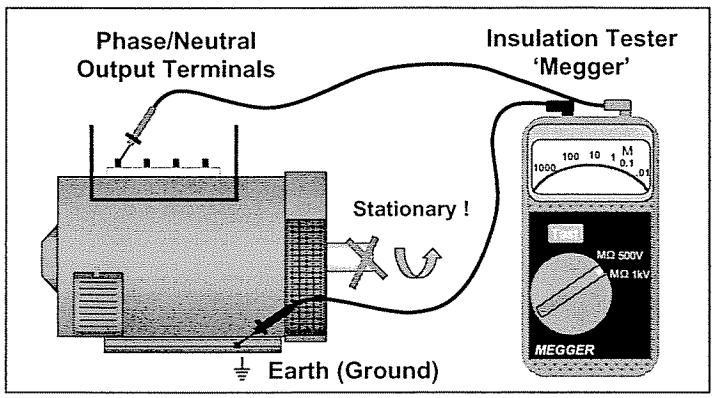
Insulation Resistance to Earth

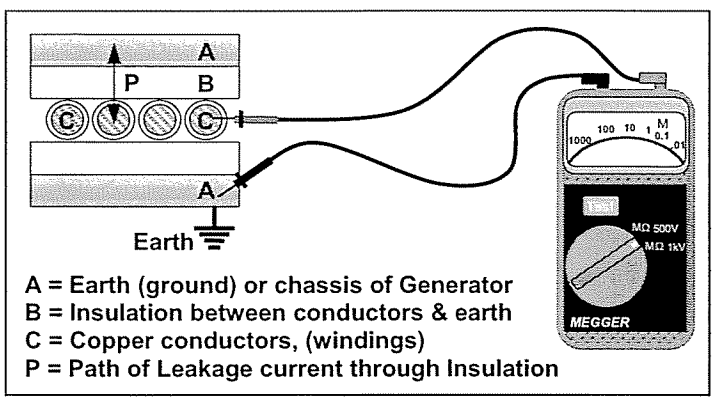
Low Voltage Generators 100 – 690VAC.

Note
When conducting high voltage test to earth, it is advisable to either disconnect or short out any electronic devices, such as the Automatic Voltage Regulator, (AVR), and Main rotor diodes.
Short circuiting the terminals can be achieved with a piece of fuse wire, which must be removed immediately after the tests are completed.

Caution: Running the Generator before removing the short circuit connection could seriously damage the Generator.
When Megger testing a machine, failure to protect the voltage control unit and diodes could result in permanent damage to one or more of the electronic components.

The resistance of the insulation between the copper conductors and the frame of the machine, (earth or ground), is measured by means of a high voltage tester, or "Megger", which applies a D.C. potential of 500 or 1000 volts across the winding insulation.





The high voltage causes a current to 'leak' through the insulation system. This current produces an output reading on the Insulation tester ('Megger'), which is measured in Megohms (resistance to earth or ground). A normal value for a low voltage Generator winding should be higher than 1 Megohm to earth.

Generators with an output voltage of between 100V to 600V should be tested as above. If the output winding (stator) is lower than 1 Megohm to earth, the windings should be cleaned, dried, or removed to a workshop for complete refurbish.

Insulation Resistance to Earth

Medium to High voltage Generators, 1k Volt or higher

High voltage generators are capable of storing a dielectric (capacitive) charge in the main stator windings, following a high voltage insulation test.

Danger !

Any testing of the main stator must be followed by a discharge to earth or ground for at least 1 minute. Do not attempt to touch the main output terminals until all residual charge has been discharged.

Insulation testing of Medium and High voltage generators .

The effectiveness of a particular on-site test will depend to a large extent on the machine application. In many situations, measurements of insulation resistance and polarisation index only will be appropriate. More detailed testing involving loss tangent, dielectric loss analysis, partial discharge measurement, is undertaken at intervals in order to establish the extent of deterioration of insulation condition. Other tests such as high voltage withstand tests are particularly effective for investigative work in order to identify the onset of fault conditions.

Polarisation Index Test (P.I.)

The P.I. test is used as a guide to the dryness, cleanliness and safety of the winding insulation system.

A special motorised insulation tester is required, which can maintain a test voltage of 1 - 2.5kV, (medium voltages), or 5kV, (high voltage), for a period of 10 minutes.

Readings are taken (in Megohms) following a 1 minute and 10 minute time interval: -

The P.I. index is obtained by the formulae:-

$$\text{P.I.} = \frac{\text{1 Minute reading}}{\text{10 Minute reading}}$$

The resultant ratio is called the P.I. index, and should be a minimum of 2 at 20°C.
A P.I. index below 1.5 suggests the windings are wet, dirty or faulty, and should be cleaned, dried, and refurbished as necessary.

Caution! **Do not test any winding other than the main stator with this method.**

SECTION 3

FAULT FINDING 'METHOD A' FOR ALL GENERATORS SEPARATELY EXCITING WITH A BATTERY

Danger !

It is essential that all instruments be regularly checked for safety, and any connection leads, probes or clips checked to ensure that they are suitable for the voltage levels being tested.

Never attempt to test a "LIVE" generator unless there is another competent person present who can switch off the power supply or shut down the engine in an emergency.

Never expose "LIVE" connections unless you have created a safe working area around you. Make sure you have made all other persons in the immediate area fully aware of what you are doing.

Caution ! Insulation Resistance to Earth

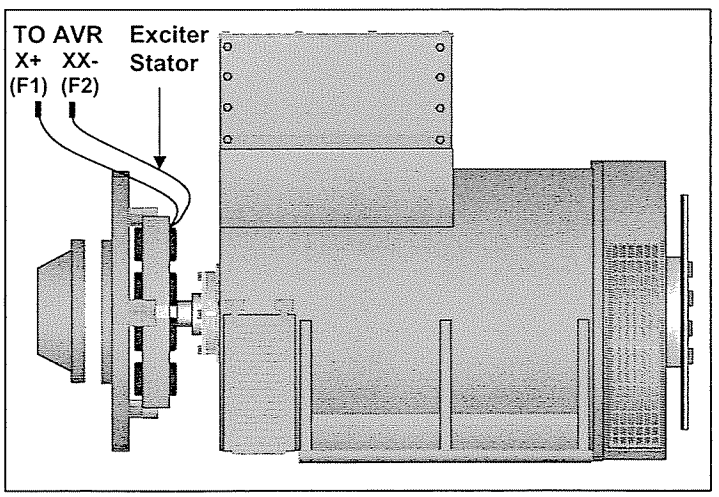
Before conducting the following tests, the Insulation of the main stator windings should be checked, in the methods described in Section 2 , 'Insulation Resistance to Earth'.
Minimum Insulation to Earth for the Main Stator is 1.0 Megohm.

Fault Finding Method 'A'

Success with this method depends upon each test being completed before proceeding to the next, unless otherwise stated.
Every component in the alternator is checked regardless of the symptoms of the fault, with the exception of the voltage control system, which is covered in test Method B, Sections 4 & 5.

1. Set up for test

Disconnect the Exciter Stator leads positive and negative, from the Automatic Voltage Regulator (AVR).
These terminals are marked X+ (F1), and XX- (F2), respectively.



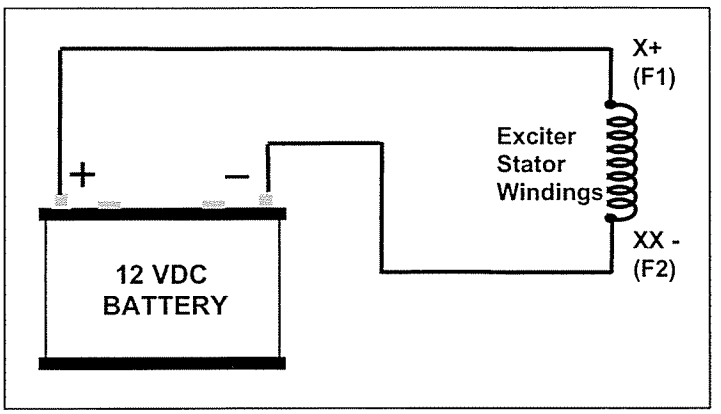
Note
Ensure that the correct two exciter leads are identified, by physically tracing them back to the exciter stator windings, fitted inside the non-drive end bracket of the Generator.

2. Check the Exciter Stator Resistance

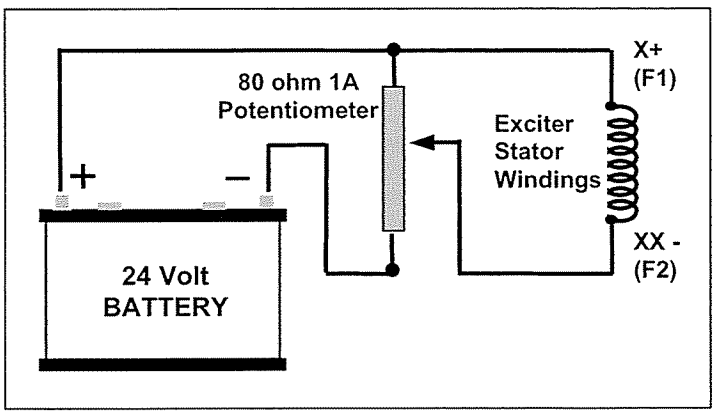
Check the resistance value of the exciter stator across these two leads (approximately 18-30 ohms) with a Multimeter. Refer to Operation and Maintenance manual for correct values.

3. Battery Test

Connect the D.C. battery supply to the exciter stator leads, positive to X+ or orange (F1), negative to XX- or black (F2).



A variable source can be applied to the circuit, as shown: -



4. Run the Generator at Nominal (normal) Speed.

Ensure that the speed is within 4% of the nominal. The engine speed must be correct, to avoid misleading test results.

5. Excitation Voltage at No Load

It is essential that ALL LOAD is disconnected from the machine, and that the speed is correct.

Check the Battery Voltage after connecting to the Exciter Stator, a minimum of 12 VDC is required.

When testing with a fixed battery supply, any difference between the figures below, and the actual battery voltage, will effect the test results, and should be taken into account. For example, if your battery voltage is 10% higher or lower than the figures shown, you can expect the Generator voltage to be equally 10% higher or lower than expected.

The following chart gives the approximate D.C. battery voltages required to produce nominal output voltage ± 10% from the Generator at no load.

FRAME SIZE	EXCITATION AT NO-LOAD
BC16 & 18	10 -12 VOLTS D.C.
UC22 & 27	10 -12 VOLTS D.C.
HC / SC 1	10 -12 VOLTS D.C.
HC / SC 2	10 -12 VOLTS D.C.
HC / SC 3	9 - 11 VOLTS D.C
C20, C30, C40	9 -11 VOLTS D.C.
HC / SC 4 , 5	10 -12 VOLTS D.C.
C45 ,C50, C60, C604	11 -12 VOLTS D.C.
HC / SC/ AC 6	12 -13 VOLTS D.C.
HC / SC / AC 7 & F8	12 -14 VOLTS D.C

6. Checking the Generator Output Voltage

Using a Multimeter, test the output voltage across the main terminals, Phase to Phase, and Phase to Neutral.
If the output voltage from the main stator is within 10% of the nominal, or higher than the nominal, and balanced across phases, this indicates that the main stator, the, main rotor, exciter stator, exciter rotor, and main rectifier diodes, are all functioning correctly.
Proceed directly to Test Number 13.

If the output is unbalanced phase to phase, or more than 10% below the nominal, this indicates that a fault exists in one of the above components, and the following tests must be conducted

7. Checking the Main Stator Winding

The voltages between phases, and each phase to neutral, should be balanced, to within 1% of the nominal voltage.
On a single-phase machine the voltage between L1-L4, and L2-L4 or U-N and W-N, must be balanced.
If the voltage is 10% or more below the nominal voltage, but is balanced within 1% phase to phase, proceed to test number 9.

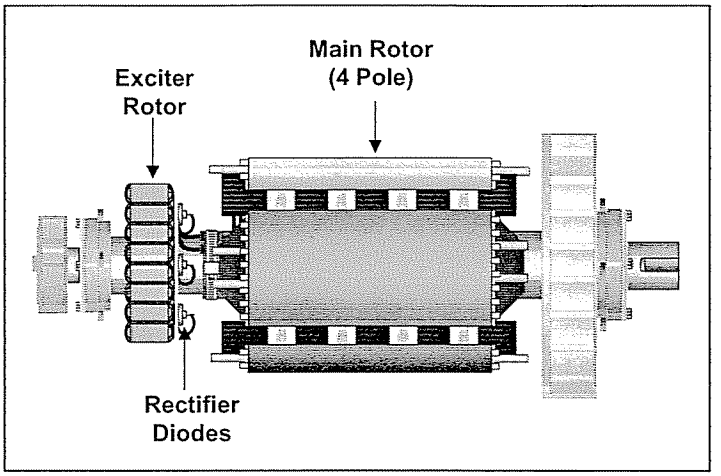
If the voltage is unbalanced by more than 1%, this indicates that a fault exists with the main stator windings.
This test should be repeated with all external connections removed from the Generator terminals, to eliminate the possibility of external shorts in the output cables, or the circuit breaker.
Further tests may be made on the resistance values of the main stator windings with a Kelvin Bridge resistance test meter.
(refer to the Operation and Maintenance manual for main stator winding resistance values).

8. Symptoms of a Main Stator Fault

A fault in the main stator windings will produce short circuit currents between the coil turns in the windings.
When separately exciting with a battery, the current will also create heat in the damaged winding, which can also be heard as a slight loading of the engine.
The three fault symptoms: 1.Unbalanced Voltages. 2. Heat and/or a burning smell from the windings. 3. Engine sounds loaded, are all indications of a faulty main stator winding.
A faulty winding must be repaired or replaced.

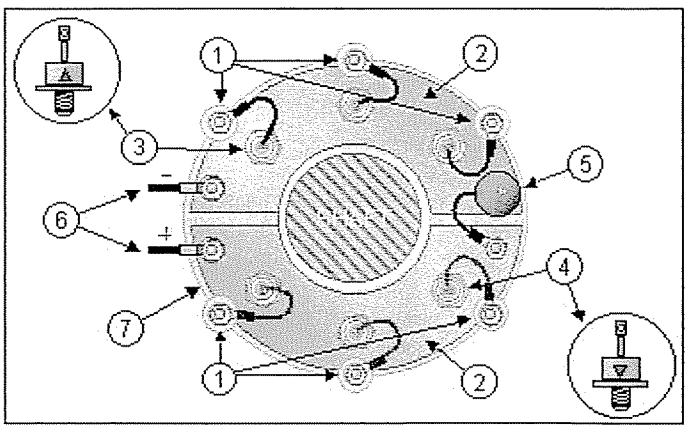
9. Voltage is Balanced but reading Low

If the output voltage is more than 10% below the nominal voltage, but is balanced within 1% Phase to Phase, (or Phase to Neutral), the main stator is OK, but there is a fault elsewhere.
This indicates that a fault exists in either the main rotating rectifier assembly, (diodes and Varistor), or one of the excitation windings, (the main rotor, or exciter stator, or exciter rotor).
First check that the D.C. battery supply is not lower than the figure given in Paragraph 5, and that the engine speed is correct. This could give misleading results if incorrect.



10. Testing the Rotating Rectifier Assembly

The diodes on the main rectifier assembly can be checked with a multimeter. The flexible leads connected to each diode should be disconnected at the terminal end, and the forward and reverse resistance checked. (See section 2, diode testing).
The rectifier assembly is split into two plates, positive and negative, and the main rotor is connected across these plates. Each plate carries 3 diodes, the negative plate carries the negative based diodes, and the positive plate carries the positive based diodes. Care must be taken to ensure that three identical polarity diodes are fitted to each plate. When fitting the diodes to the plates they must be tight enough to ensure a good mechanical and electrical contact, but should not be over tightened. The recommended torque tightening is 4.06 to 4.74 Nm, (14 to 17 kg/cm).



Rectifier Components

1. A.C Connection Stud
2. Rectifier Plates
3. Diodes - 3 X Negative
4. Diodes - 3 X Positive
5. Surge Suppressor (Varistor)
6. Main Rotor Leads
7. Rectifier Hub

11. Testing the Surge Suppressor (Varistor)

The Surge Suppressor (Varistor), is a protection device, which prevents high voltage transients from damaging the main rectifier diodes.
High Voltage transients are created by fault conditions in the distribution system. The Voltage transient returns back to the Generator output terminals, enters the main stator windings, and by mutual inductance, is transferred to the main rotor windings, and the main rectifier assembly.
The Surge Suppressor can be tested with a Multimeter on Megohms range.
A good Surge Suppressor should have a very high resistance, (more than 100 Megohms in either direction).
A faulty Surge Suppressor will be either open circuit (usually showing signs of burning) or short circuit in both directions.
The Main Rectifier will work normally with this device removed. However, it should be replaced as soon as possible, to avoid diode failure in the event of further transient fault conditions.

Occasionally, a very high transient may totally destroy the Surge Suppressor. This would result from extreme fault conditions, such as lightening, (electric storms), close to overhead distribution lines, or out of phase synchronisation of the Generator, when paralleled to multiple Generator systems, (or the Mains, Utility, supply).

In the event of a Surge Suppressor failure, all rectifier diodes should be replaced, including any which appear to test OK.

12. Testing the Main Excitation Windings

After establishing and correcting any fault on the rectifier assembly, the battery test should be repeated, from paragraph 6, and the output voltage checked.
If the output voltage is still more than 10% below the nominal voltage when separately excited, this indicates that the fault must be in one of the excitation windings.
To test the main rotor, exciter stator and exciter rotor winding, the resistance values must be checked against correct values, which are given in the Operation and Maintenance handbook, supplied with the generator.
Refer to the Service and Maintenance section, for the winding resistance charts, specific to each Generator type and size.
Note. The charts require identification of the frame size, number of rotor poles, followed by the main stator and rotor core length (A, B, C–G, H, J etc). The Main Stator core length and winding number are shown on the Generator nameplate.
If in doubt, refer to the factory, with the Generator serial number or machine I.D number, for identification.

Exciter Stator

The exciter stator resistance is measured across leads X+ and XX- (F1 and F2), which should be disconnected from the Automatic Voltage Regulator (AVR), terminals.
A standard Multimeter, set on the lowest resistance range, will be suitable for this test.
The exciter Stator winding Insulation to earth should also be tested with a 'Megger'. As a low insulation can effect the AVR performance. Minimum value 1 Megohm. (See section 2 for details).

Exciter Rotor
The exciter rotor is connected to the 6 X AC connection studs on the Main Rectifier assembly.
Disconnect the 6 leads from the AC connection studs, and check the resistance value across three of the leads, which are connected to the same polarity diodes, (bolted to the same rectifier plate). The resistance value is very low, and requires a Kelvin Bridge test meter for accurate results. A visual inspection will usually identify any burnt or damaged windings.

Main Rotor
The main Rotor leads are connected to the main rectifier plates. Disconnect one of the leads to check the resistance value.
A good quality Multimeter will measure resistances of 0.5 to 2 ohms with reasonable accuracy, however if the resistance is found to be lower than the quoted figure, it should be verified with a more accurate measurement.

13. Testing the AVR Sensing Supply (feedback).

Checking the sensing supply from the main stator is the final test, which can be carried out while separately exciting the Generator with a battery supply. Make sure the output voltage is approximately correct, I.e. within 10% of the nominal voltage).

The previous tests should have cleared any fault in the windings or rectifier assembly and the correct output obtained from the main stator with the battery.

With the Generator running at nominal voltage, the sensing supply should be between 190 and 240 volts. If the supply is incorrect, or unbalanced, the fault should be traced back via the wiring circuit to the Main Stator connections

Two phase sensed AVR's, MK11A, SX440, MX341, SX460, SA465
The sensing supply is across AVR terminals 2 and 3, (AVR types MX341 and SX440), or 7 and 8 (AVR types SX460 and SA465).

Note. Generators supplied before 1989. The parallel droop CT, and close regulation CT, (when fitted), is connected into the sensing supply via a burden resistor, fitted in the terminal box.
Refer to the Operation and Maintenance manual supplied with the Generator for details.

Three phase sensed AVR's, MX321, MA325, MA327
The sensing supply is connected to the AVR terminals marked 6, 7, and 8.

Note 1. The Sensing Supply is connected via an isolation transformer, or an isolation module, (PCB), fitted in the Generator terminal box. Check primary and secondary of transformer, or input and output of PCB.

Note 2. Generators supplied before 1989. The parallel droop CT, and close regulation CT, (when fitted), is connected into the sensing supply via a burden resistor, fitted in the terminal box.
The sensing supply is connected via a separate 3 Phase Sensing unit, the sensing supply leads 6,7, & 8 are connected to the 3 phase sensing unit, which has a DC output to the AVR.

Refer to the Operation and Maintenance manual supplied with the Generator for details.

SECTION 4
SELF EXCITED CONTROL SYSTEM
TEST METHOD B
FAULT SYMPTOMS AND REMEDIES AT NO LOAD

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
NO VOLTAGE (NO LOAD)	1) Voltmeter connected incorrectly, or faulty.	Check and verify voltage at Generator terminals with a multimeter.
	2) Loose broken or corroded connections.	Check all auxiliary terminals. Check the AVR push on terminals for tightness. Repair or renew where necessary.
Loss of Residual Voltage  	3) Loss of residual can occur after :- (i) Many years storage prior to use. (ii) Reversal of the Exciter Stator magnetic field while 'flashing' with a battery. (iii) Rewind of the Exciter Stator. (iv) Mechanical 'shock' to the Exciter Stator laminated core, (where residual magnetism is stored). **Note.** Series 3 AVR systems with Permanent Magnet Generator do not rely upon residual voltage for voltage build up.	With Generator running at rated speed, without load, briefly connect a 12 volt D.C. battery supply, with a blocking diode in one lead, to AVR terminals X+ (F1) and XX- (F2).(see figure left). Maximum connection time 1 second. **CAUTION!** **Never connect a battery to the AVR terminals, without a blocking diode. In most cases this will destroy the AVR power devices.** **Battery polarity MUST be correct!**
NO VOLTAGE (NO LOAD)	4) Very low insulation resistance to earth (ground),on exciter stator or main stator.	Check the insulation resistance value with a Megger (see section 2). (Disconnect AVR during this test, and remove any Neutral earth connection).
	5) Surge suppressor on main rotating rectifier short circuit.	Check surge suppressor resistance (see Section 3 Test Method A).
	6) Main rectifier diode(s) short circuit.	Carry out Test Method A, Section 3. Replace where necessary. Check diodes (See Section 2)
	7) Winding fault. Open circuit or short circuit on any winding in the machine.	Carry out all tests as listed in Test Method A. Check winding resistance values.
	8) Exciter stator polarity reversed by battery tests. Also see "Loss of Residual Voltage" which may be caused by polarity reversal.	Re-connect battery to exciter stator ensuring that polarity is correct, and re-test. Restore residual magnetism as Item 3 above.
	9) Fault in AVR.	Replace the AVR and re-test machine.
	10) Load applied to machine during run up of engine.	The voltage may not build up until the load is disconnected from the machine. Open circuit breaker and re-test.
	11) Open circuit power supply from main stator to AVR terminals P2, P3, P4. (SX440), or 7 and 8 (SX460 and SA465).	Separately excite machine as per test method A, Section 3. Check voltage across AVR terminals P2, P3, P4, or 7 & 8. AVR power supply should be between 190 to 240VAC.

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
LOW VOLTAGE (NO LOAD)	1) Engine speed low. Under frequency protection (UFRO) circuit activated.	Check AVR LED. If lit, UFRO is activated, indicating low speed. Check speed with tachometer. Adjust governor control to nominal speed, or up to maximum (+4%) of nominal speed.
	2) AVR 'VOLTS' adjust, or external hand trimmer control incorrectly set.	Adjust voltage on AVR 'volts' trim, or remote trimmer. Ensure that speed is correct, and UFRO is OFF. (See above).
	3) Voltmeter faulty or sticking.	Check and verify voltage across machine output terminals, with a Multimeter.
	4) Fault in AVR.	Replace AVR and re- test.
	5) Loose broken or corroded connections.	Check the wiring for poor connections. Repair or replace where necessary.
	6) Fault on power supply from main stator.	See item 11, previous test under "No voltage, at no load".
HIGH VOLTAGE (NO LOAD)	1) Sensing supply from Main Stator to AVR open circuit or too low.	Check sensing supply voltage, as per Test Method A, Section 3, (item 13).
	2) AVR 'VOLTS' control or hand trimmer incorrectly set.	Adjust as necessary. Ensure that the engine speed is correct first.
	3) Sensing supply transformer faulty.	AVR sensing supply circuit via dropper transformer, (4 or 6 wire Generators), or sensing PCB. Check sensing supply as per Test Method A, Section 3, (item 13).
	4) Burden resistor, fitted in AVR sensing supply, corroded or open circuit. (Pre 1987 Generators only.)	A fault on the burden resistor can create a high voltage condition. Check tapping bands. Normal resistance value 215 ohms.
	5) AVR faulty.	Replace AVR and re-test.
	6) Loose, broken or corroded connections.	Check connections on auxiliary terminal board and AVR terminals. Repair or replace if necessary.
UNSTABLE VOLTAGE (NO LOAD)	1) Engine governor unstable (hunting).	Check for speed instability with a frequency meter, or tachometer. Sometimes this problem will clear when a load is applied to the engine.
	2) AVR Stability settings.	Check AVR stability links, adjust stability potentiometer.
	3) Loose or corroded connections.	Intermittent voltage fluctuations can be created by poor connections. Check auxiliary and AVR terminals.
	4) Intermittent earth (low insulation resistance).	Megger all windings, (see section 2), including Exciter Stator, low insulation resistance can effect the AVR.
	5) Faulty AVR.	Check AVR for corrosion or broken components. Replace AVR and re-test
	6) Voltmeter faulty/unstable.	Panel mounted voltmeters are sensitive to vibration. Check and verify readings.
UNBALANCED VOLTAGE (NO LOAD).	1) Fault on main stator windings.	Disconnect all external leads to Generator and re-test. Separately excite, (Test Method A Section 3). A winding short will get hot, and engine will sound slightly loaded. Shut down set and check by hand for hot spots.

FAULT SYMPTOMS AND REMEDIES WHEN ON LOAD

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
UNBALANCED VOLTAGE (ON LOAD).	1) Single-phase loads (phase - neutral) unevenly distributed over the three phases.	Check current in each phase with clip-on ammeter. The full load rated current must NOT be exceeded on any individual phase. Re-distribute load if necessary.
UNSTABLE VOLTAGE (ON LOAD).	1) Engine governor unstable (hunting)	Check with a frequency meter or tachometer for speed variations due to governor 'hunting', or cyclic irregularities in the engine.
	2) Leading Power Factor load created by power factor correction capacitors.	Isolate the power factor correction capacitors until sufficient inductive load has been applied. (See Power Factors, Section 2).
	3) Fluctuations in load current, (motor starting, or reciprocating loads).	Check the load current on a stable supply, i.e. mains, or separately excite the machine. A variable D.C. supply is required for on load separate excitation tests. (see test method A, section 3).
	4) Non linear load creating waveform distortion. (Contact factory for further information on non-linear loads).	Use Permanent Magnet Generator (PMG), powered control system (AVR).
	5) AVR stability incorrectly adjusted.	Adjust AVR, until voltage stabilises.
HIGH VOLTAGE (ON LOAD)	1) Unbalanced load.	Check voltages on all phases. If unbalanced, re-distribute loading over three phases.
	2) Leading Power Factor load (capacitor banks).	Check excitation volts across X+, (F1) and XX- (F2). A leading power factor will give an abnormally LOW DC excitation. Remove power factor correction equipment at low loads (see Power Factors Section 2).
	3) Parallel droop current transformers reversed.	Check for droop reversal. (See section 6, parallel operation).
	4) Burden resistor incorrectly set across improved regulation transformer. (Pre 1989 machines only).	Reduce the amount of resistance across the improved regulation transformer until on-load voltage is correct.
POOR VOLTAGE REGULATION (ON LOAD)	1) Large speed droop on engine. AVR UFRO protection activated.	Check that the speed droop from no load to full load is no greater than 4%. Check AVR LED, if LIT, increase engine speed.
	2) Unbalanced load.	Check voltage and load current on all phases. If unbalanced, redistribute the load more evenly across the phases.
	3) Parallel droop circuit incorrectly adjusted, or requires shorting switch for single running.	The droop circuit will give additional voltage droop of -2½ % at full load 0.8 pf. For single running machines this can be improved by fitting a shorting switch across the droop CT input, (S1 – S2), on the AVR. (Pre 1989 machines, short across the burden resistor in the terminal box).
	4) Voltage drop between machine and load, due to I^2R losses in supply cable. (This will be made worse by motor starting current surges, etc).	Check the voltage at both ends of the cable run at full load. Differences in voltage indicates a volts drop along the cable. In severe cases, a larger diameter cable is required.
	5) Improved regulation equipment reversed. (Pre 1989 machines only).	Reverse the secondary leads on the transformer, and re-test on load.

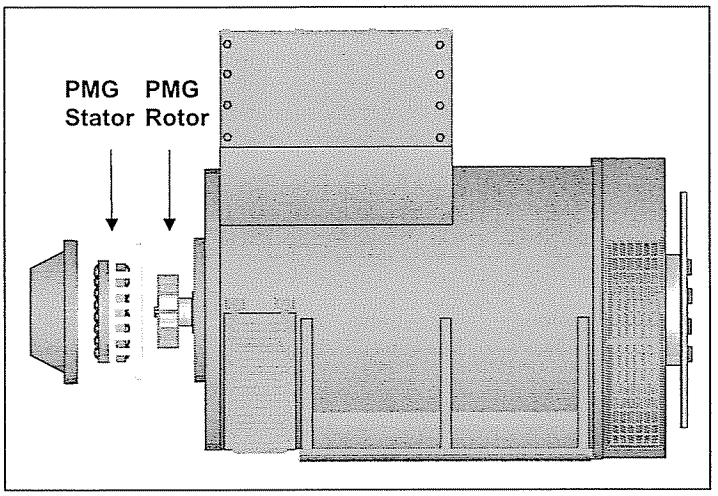
SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
POOR VOLTAGE REGULATION cont.. (ON LOAD)	6) Fault on main rectifier or excitation windings.	Check the no-load excitation volts across AVR X+ (F1) and XX- (F2). Compare with the D.C. voltages as listed in Test Method A Section 3. If much higher than listed, carry out Test Method A.
	7) AVR Under frequency protection circuit, (UFRO), activated.	Check AVR LED, If lit, UFRO is activated, (engine speed is low). Check engine speed and adjust to correct nominal speed, (or frequency).
POOR VOLTAGE RESPONSE TO LOAD SURGES OR MOTOR STARTING	1) Engine fault or engine governor unable to respond, (speed drop too low).	Check performance of engine during application of load. Check if AVR LED is lit during motor starting. Check if AVR 'DIP' or 'DWELL' engine relief circuits are activated. Adjust as necessary. (See AVR instruction sheet for details).
	2) Parallel droop circuit incorrectly set.	Too much droop will increase voltage dips when motor starting. Fit shorting switch for single running Generators. (See parallel section 6).
	3) Load surges exceed 2.5 times the full load current.	Check load surges with a clip-on ammeter. Voltage dip may be excessive if the current exceeds 2.5 times full load. Refer to factory for motor starting calculations.
	4) Voltage drop between Generator and load, due to I^2R losses in the cable. This will be worse during current surges (motor starting etc).	Check the voltage at both ends of the cable run at full load. Differences in voltage indicates a volts drop along the cable. In severe cases, a larger diameter cable is required.
	5) Motor contactors dropping out during starting, (large current surges, Voltage dips greater than 30%).	All symptoms and remedies in this section may apply to this problem. Refer to factory for typical voltage dips.
	6) AVR "Stability" control incorrectly adjusted.	Adjust AVR 'Stability' control anticlockwise until voltage is unstable, then slightly clockwise until stable.
	7) Fault on windings or rotating rectifier.	Any fault in this area will appear as high excitation voltage across X+ (F1) and XX- (F2), higher than figures listed in Section 3. Complete Test Method A Section 3
	8) AVR UFRO and/or engine relief circuit activated during motor starting.	Check performance of engine during application of load. Check if AVR LED is lit during motor starting. Check if AVR 'DIP' or 'DWELL' engine relief circuits are activated. Adjust as necessary. See AVR instructions for details.
	9) Faulty AVR.	Replace and re-test on load.

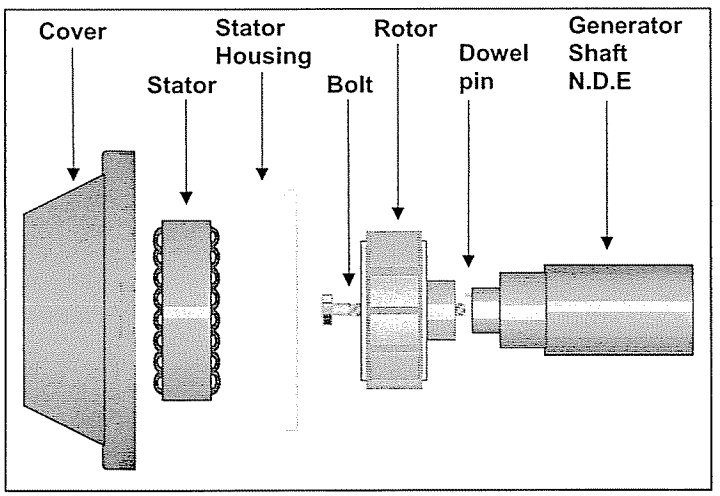
SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
LOW VOLTAGE (ON LOAD)	1) Engine speed droop greater than 4%.	Check if AVR LED is lit, UFRO is activated, (low speed indication).Check engine speed no load and full load. Engine governing should be within + 4% and –1% of nominal speed. Reset as necessary.
	2) Under frequency protection circuit operational (UFRO).	Check AVR LED. If lit, UFRO is activated, increase engine speed to correct levels.
	3) Fault in AVR power supply from main stator.	Separately excite machine as per test method A, Section 3. Check voltage across AVR terminals P2, P3, P4, or 7 & 8. Normal AVR power supply should be between 190 to 240VAC.
	4) AVR faulty.	Replace AVR and re-test.
	5) Fault on winding or rotating diodes.	Any fault in this area will appear as high excitation voltage across X+ (F1) and XX- (F2), higher than figures listed in Section 3. Complete Test Method A Section 3
	6) Voltage drop between Generator and load, due to I^2R losses in the cable. This will be worse during current surges (motor starting etc).	Check the voltage at both ends of the cable run at full load. Differences in voltage indicates a volts drop along the cable. In severe cases, a larger diameter cable is required.

SECTION 5
SEPARATELY EXCITED CONTROL SYSTEM WITH PERMANENT MAGNET GENERATOR (PMG)

The Permanent Magnet Generator (PMG)

The PMG rotor shaft is located onto the non-drive end of the Generator shaft. A spigot fits over the shaft end, and the whole assembly is secured by a single bolt through the PMG rotor, into a threaded hole in the shaft .
The PMG stator is fitted to the non-drive end bracket of the Generator, either directly into a spigot on the non-drive end bracket, or bearing cap, or into a housing as shown below.





PMG powered AVR's (Series 3)
The PMG provides an independent power supply for the Automatic Voltage Regulator (AVR).
Series 3 (PMG Excited), AVR types are designated 'MX' or 'MA', to identify them as PMG powered AVR's.
Series 4 (Self-Excited), AVR types are designated 'SX' or 'SA', and are unsuitable for use with a PMG power supply.

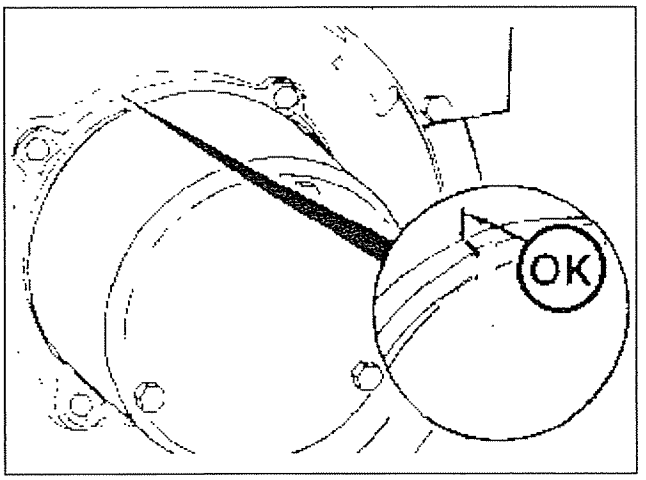
Testing the Permanent Magnet Generator

The PMG can be tested as an independent Generator.
Disconnect the AVR power supply leads marked P2, P3, P4, from the AVR terminals.
Run the Generator at nominal speed (the speed must be correct for accuracy of results).
Check the PMG output Voltage across leads P2, P3, and P4 with a multimeter, set to AC volts.
For 50 Hz Generators, Voltage across P2, P3 and P4 should be approximately 170VAC.
For 60Hz Generators, Voltage should be approximately 200VAC.

PMG's manufactured before 1983.

The PMG stator has a lead marked P1, which is the Neutral connection. The Voltage from P1, (Neutral), to P2, P3, and P4 should be /1.732 of the phase to phase voltage.
Note: This lead is not required for later AVR types, and can be removed if the original AVR is replaced.

Series 3 AVR's manufactured before 1989



The radial position of the PMG Stator was important for adjustment of the AVR response and regulation.
For Pre-1989 Generators, the PMG stator is fitted into a housing, which is clamped to the Generator non-drive end bracket.
Release of the clamps allows the PMG stator housing to be rotated in its spigot.
The correct radial position of this housing is marked at the top, (12 O'clock position), on the housing and end bracket.
When work is carried out which requires the dismantling of the PMG, care should be taken during re-assembly, to ensure that the PMG stator is returned to its original radial position.
NOTE: Series 3 AVR's manufactured after 1989
If the original pre-1989 AVR is changed for a later model, the radial position of the PMG Stator is not important.

SECTION 5

SEPARATELY EXCITED CONTROL SYSTEM
WITH PERMANENT MAGNET GENERATOR (PMG)
TEST METHOD B
FAULT SYMPTOMS AND REMEDIES AT NO LOAD

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
NO VOLTAGE (NO LOAD)	1) Faulty permanent magnet generator (PMG), stator or rotor.	Disconnect the PMG leads from AVR terminals P2, P3, P4. Check voltage across leads with a Multimeter, with the set running at correct speed. For 50Hz, Voltage across P2, P3 and P4 should be approx. 170VAC. For 60Hz, Voltage is approx. 200VAC. Pre 1983 machines. Lead P1 from the PMG is the Neutral. Voltage P1 to P2, P3, & P4 should be /1.732 of phase to phase voltage.
	2) Insulation failure to earth, (ground), on permanent magnet stator.	Disconnect leads P2, P3, P4 and, 'Megger' test to earth, (see Section 2).
	3) Voltmeter faulty.	Check and verify voltage at Generator output terminals with a Multimeter.
	4) Loose, broken or corroded connections.	Check connections, repair and replace where necessary.
	5) AVR High excitation protection circuit activated, collapsing output voltage. (AVR protection circuit is factory set to trip at 70VDC across AVR output).	Check if AVR LED is LIT, indicating protection circuit activated. Shut down the engine, and run up again. If the voltage builds up normally but collapses again, the protection circuit has operated, & AVR LED will be lit. Run again & check the excitation voltage across A.V.R X+ (F1) and XX- (F2). If greater than 70 VDC, the protection circuit is operating correctly. Carry out Test Method A, Section 3, to establish cause of high excitation volts.
	6) Main Rectifier diodes short circuit.	Check diodes (see Section 2). Carry out Test Method A Section 3.
	7) Open circuit in exciter stator windings.	Remove external leads from Generator, and carry out all tests as per Test Method A, Section 3.
	8) Faulty AVR .	Replace AVR and re-test..
	9) Winding fault, open circuit or short circuit.	Remove external leads from Generator, and carry out all tests as per Test Method A, Section 3.

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
LOW VOLTAGE (NO LOAD)	1) Engine speed low	Check LED on AVR. If lit, UFRO protection is activated, indicating low engine speed. Adjust engine speed to correct nominal.
	2) Under frequency protection (UFRO) circuit operational.	Check if LED on AVR is lit, indicating low engine speed. Adjust engine speed to within –1% to +4% of nominal.
	3) Voltmeter faulty or 'sticking'.	Verify voltage across Generator output terminals with a Multimeter
	4) AVR 'VOLTS' adjust incorrectly set	Adjust control CLOCKWISE to increase voltage. If remote hand trimmer fitted, adjust in conjunction with trimmer.
	5) Faulty AVR	Replace AVR and re-test.
HIGH VOLTAGE (NO LOAD)	1) AVR 'VOLTS' adjust or remote trimmer incorrectly set.	Check and adjust as necessary.
	2) Low sensing supply from main stator.	Check sensing supply as per Test method A Section 3, paragraph 13.
	3) Sensing supply open circuit to AVR terminals 2 and 3, (AVR MX341), or 6, 7 & 8, (MX321, and all MA type).	Open circuit or low sensing signal will cause the AVR to produce high excitation, which will produce a high output Voltage. Check sensing supply as per Test method A, Section 3, paragraph 13.
	4) Burden resistor open circuit. (Pre 1989 machines only).	Disconnect burden resistor, (fitted in terminal box), and check resistance (215 ohms). Also check tapping bands and connections for corrosion and tightness.
	5) Faulty AVR.	Replace AVR and retest machine
UNSTABLE VOLTAGE (NO LOAD)	1) Engine speed 'hunting' (unstable).	Check with a frequency meter or tachometer for speed variations due to governor 'hunting', or cyclic irregularities in the engine. This may improve as load is applied.
	2) Permanent magnet stator incorrectly positioned. (Pre 1989 AVR only).	The radial position of the stator housing is important for the stability and response of the AVR. (See start of Section 5 for details). Later AVR models do not require this adjustment.
	3) AVR stability control incorrectly adjusted.	Adjust stability clockwise until voltage stabilises. Check again on load.
	4) Loose or corroded connections.	Check push on terminals on AVR Check auxiliary terminals for loose connections. Repair or replace as necessary.
	5) Intermittent earth on machine.	Megger all windings, (see section 2), including Exciter Stator, low insulation resistance can effect the AVR.
UNBALANCED VOLTAGE (NO LOAD)	1) Fault in main stator winding.	Disconnect all external leads to Generator and re-test. Separately excite Generator, (Test Method A Section 3). A winding short will get hot, and engine will sound slightly loaded. Shut down set and check by hand for hot spots.

FAULT SYMPTOMS AND REMEDIES WHEN ON LOAD

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
UNBALANCED VOLTAGE (ON LOAD)	1) Single-phase load current unevenly distributed over the three phases.	Check the current in each phase with clip-on ammeter. The full load rated current must not be exceeded on any one (single) phase. Re-distribute load if necessary.
UNSTABLE VOLTAGE (ON LOAD)	1) Engine governing unstable (hunting)	Check with frequency meter or tachometer for engine governor 'hunting', or cyclic irregularities in the engine.
	2) Leading power factor load created by power factor correction capacitors.	Isolate the power factor correction capacitors until sufficient motor load has been applied to counteract the leading power factor. (See Power Factors Section 2.)
	3) Permanent magnet stator positioned incorrectly (Pre 1989 AVR's only).	The radial position of the stator housing is important for the stability and response of the AVR. Later AVR models do not require this adjustment. (see start of this section for details.
	4) Non linear loads, causing interaction between dynamic closed loop control systems.	Interaction of closed loop systems controlling the load, the generator, and the engine. Instability caused by oversensitive control settings. Adjust AVR to high gain, (stability), and load drives to low gain. Increase engine speed 'droop' to reduce sensitivity. Contact factory for further advice regarding non-linear loads.
	5) Fluctuations in load current, (motor starting, or reciprocating loads).	Check the load current on a stable supply, i.e. mains, or separately excite the machine. A variable D.C. supply is required for on load separate excitation tests. (see test method A, section 2).
	6) AVR stability control incorrectly adjusted.	Adjust AVR control, until voltage is stable
POOR VOLTAGE REGULATION (ON LOAD)	1) Large speed droop on engine. AVR UFRO protection activated.	Check that the speed droop from no load to full load is no greater than 4%. Check AVR LED. If LIT, increase engine speed.
	2) Parallel droop circuit incorrectly adjusted, or requires shorting switch for single running.	The droop circuit will give additional voltage droop of -2½ % at full load 0.8 pf. For single running machines this can be improved by fitting a shorting switch across the droop CT input, (S1 – S2), on the AVR. Pre 1989 machines. Short across the burden resistor in the terminal box. (See section 6 parallel operation).
	3) Unbalance load.	Check voltage and load current on all phases. If unbalanced, redistribute the load more evenly across the phases.
	4) AVR stability adjustment incorrectly set.	Adjust 'stability' anticlockwise until voltage becomes unstable. Adjust slightly clockwise until voltage stabilises.

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
POOR VOLTAGE REGULATION cont. (ON LOAD)	5) Voltage drop between Generator and load, caused by losses in supply cable, (I^2R losses).	Check the voltage at both ends of the cable run at full load. Large differences in voltages indicate a large volts drop along the cable. A larger diameter cable is required in severe cases.
	6) Fault on main rectifier or excitation winding.	Check the no load excitation voltage across AVR X+ (F1) and XX- (F2). If higher than 12 volts D.C. the machine must be tested as per Section 3 Test Method A.
	7) Under frequency protection (UFRO) activated.	Check LED on AVR. If lit, UFRO is activated. (engine speed is too low). Check speed and adjust to nominal.
	8) Permanent Magnet stator position incorrect. (Pre 1989 AVR' s only).	The radial position of the stator housing is important for the regulation, and response of the AVR. (see start of section 5 for details).
POOR RESPONSE TO LOAD SURGES OR MOTOR STARTING	1) Engine governor sticking or slow to respond. AVR 'UFRO' protection circuits activated.	Check performance of engine during application of load. Check if AVR LED is lit during motor starting. Check if AVR 'DIP' or 'DWELL' circuits are activated. Adjust or de-activate, (See AVR instruction sheets).
	2) Parallel droop circuit incorrectly set.	Too much droop will increase voltage dips when motor starting. Fit shorting switch for single running Generators. Adjust droop, (See Parallel section 6) if necessary.
	3) Load current surges exceed 2.5 times full load of the machine.	Check surges with clip-on ammeter. Check with Newage for advice on voltage dips for motor starting.
	4) UFRO protection on AVR operational.	Check engine speed DIP on load application. Check LED on AVR. Low engine speed will activate UFRO protection circuit. (LED ON).
	5) Voltage drop between Generator and load, caused by I^2R losses in supply cable. This will be worse during current surges, (motor starting etc).	Check the voltage at both ends of the cable run at full load. Differences in voltages indicate a Volts drop along the cable. A larger diameter cable may be required in severe cases.
	6) Incorrect position of permanent magnet stator (Pre 1989 type A.V.R.'s only).	The position of the PM Stator affects the response performance of the AVR See following text for details.
	7) Motor contactors dropping out due to voltage dip on starting.	All symptoms and Remedies in this section may apply to this problem. Refer to factory for voltage dip calculations.
	8) AVR 'Stability' controls incorrectly set.	For best performance, adjust 'Stability' control anticlockwise until voltage is unstable, then slightly clockwise, until stable.
	9) Fault on windings or rotating rectifier.	Check the no load excitation voltage across AVR X+ (F1) and XX- (F2). If much higher than 12 volts D.C. the machine must be tested as per Section 3 Test Method A.
	10) Engine relief circuits in AVR activated.	Check if AVR has "DIP" or "DWELL" circuits. Adjust or turn out control if affecting load response.
	11) Fault in AVR.	Replace and test on load.

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
VOLTAGE COLLAPSES (ON LOAD)	1) Protection circuit in AVR activated, due to high excitation condition across AVR output, (X+ (F1) and XX- (F2).	Excitation volts higher than 70V D.C. Check across X+ (F1) and XX- (F2) on load. Ensure engine speed is correct at full load. Check output voltage, ensure it does not exceed the rated voltage. Check load current for overload.
	2) Protection circuit in AVR operated, due to fault in Generator windings or diodes.	Check AVR LED, if lit, protection circuit is activated. Shut down engine, and re-start. If voltage returns as normal, but collapses again on load, protection circuit is activated, due to high excitation. Carry out tests as per Test Method A Section 3, to identify cause of high excitation volts.
	3) Malfunction of protection circuit in AVR.	Replace AVR and test on load.
	4) Severe overload or short circuit on across phases.	Check load current with clip-on ammeter.
HIGH VOLTAGE (ON LOAD)	1) Unbalanced load.	Check voltage on all three phases. If unbalanced, re-distribute loading over the three phases.
	2) Leading Power Factor Load.	Check for capacitive (leading) PF load, i.e. kVAr correction, fluorescent lights. Apply motor (lagging) PF load, or switch off capacitors. A leading power factor load will give abnormally low D.C. excitation volts across X+ (F1) and XX- (F2).
	3) Parallel droop transformer reversed, (when fitted).	Check for reversal of droop CT, P1 - P2 or S1 - S2, reverse either to correct. See section 6 for more details.
LOW VOLTAGE (ON LOAD)	7) Engine speed droop greater than 4%.	Check if AVR LED is lit, UFRO is activated, (low speed indication).Check engine speed no load and full load. Engine governing should be within + 4% and –1% of nominal speed. Reset as necessary.
	8) Under frequency protection circuit operational (UFRO).	Check AVR LED. If lit, UFRO is activated, increase engine speed to correct levels.
	9) Faulty permanent magnet generator (PMG) stator or rotor.	Disconnect the PMG leads from AVR terminals P2, P3, P4. Check voltage across leads with a Multimeter, with the set running at correct speed. For 50Hz, Voltage across P2, P3 and P4 should be approx. 170VAC. For 60Hz, Voltage is approx. 200VAC.
	10) AVR faulty.	Replace AVR and re-test.
	11) Fault on winding or rotating diodes.	Any fault in this area will appear as high excitation voltage across X+ (F1) and XX- (F2). If higher than figures listed in Section 3. Carry out Test Method A Section 3.
	12) Voltage drop between Generator and load, due to I^2R losses in the cable. This will be worse during current surges (motor starting etc).	Check the voltage at both ends of the cable run at full load. Differences in voltage indicates a volts drop along the cable. In severe cases, a larger diameter cable is required.

SECTION 6
PARALLEL OPERATION OF A C GENERATORS

It is essential that all instruments be regularly checked for safety, and any connection leads, probes or clips checked to ensure that they are suitable for the voltage levels being tested.

Danger !

Never attempt to test a "LIVE" generator unless there is another competent person present who can switch off the power supply or shut down the engine in an emergency.

Never expose "LIVE" connections unless you have created a safe working area around you. Make sure you have made all other persons in the immediate area fully aware of what you are doing.

1. Introduction and theory

This section will explain the reasons for paralleling, the method by which it is carried out, the setting up procedures and possible problems that may arise.

Parallel Operation may be necessary for the following reasons:-

(1) To increase the capacity of an existing system.
(2) Size and weight may preclude the use of one large unit.
(3) Allows non-interruption of the supply when servicing is required.

In order to parallel AC Generators satisfactorily, certain basic conditions have to be met. These are as follows:-

(1) All systems must have the same voltage.
(2) All systems must have the same phase rotation.
(3) All systems must have the same frequency.
(4) All systems must have the same angular phase relationship.
(5) Systems must share the load with respect to their ratings.

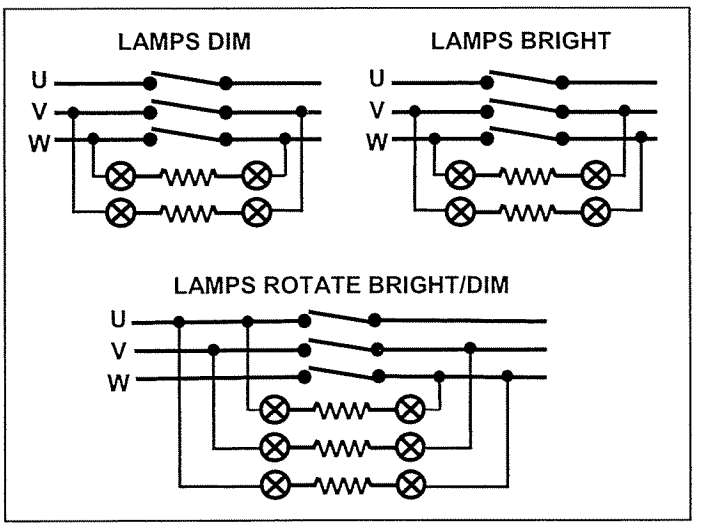
Metering and Protection
A minimum amount of instrumentation is required to ensure the above information is satisfactorily monitored, comprising an ammeter, a wattmeter and a reverse power relay. No voltmeter is specified for each system because it is preferred to use one voltmeter on the distribution or synchronising panel with a selector switch for each system. This eliminates any possible meter inaccuracies.

A reverse power relay is essential as any engine shut down, from low oil pressure or temperature etc. will result in other systems motoring the failed set, with consequent overload to the remaining systems, and/or damage to the motored engine.

Only one frequency meter is required with the facility of being switched to the busbar, or the incoming system.

Synchronising
A synchroscope and/or lights, is required to detect the angular phase displacement. If lights are used three different connections are possible. For paralleling with the lights dim, they must be connected across like phases or like lines (single phase), i.e. UU, V-V or L1-L1. For paralleling with lights bright they should be connected across unlike phases, i.e. U-V etc.

If a three-lamp system is used with the lamps connected across U-W, V-V and W-U the lamps will 'rotate' and give an indication which machine is running fast. Synchronism is reached with two lamps bright and one dark and in some respects this connection gives a closer visual indication of the point of synchronism. Note the lamps should be rated for at least twice the machine voltage or it will be necessary to connect two or three in series. A more preferred method is a resistor, in series with each lamp.
The following diagrams illustrate the connections:



NOTE: If the neutral is solidly linked, then only one set of lamp/resistors is required, because the return path is through the neutral link. This, of course, only applies to the lamps dim or lamps bright connection, and not on the three lamp connection.
Modern installations prefer to use semi or fully automatic synchronising equipment, which allows breaker closure only when conditions are correct.

Load sharing

An important aspect of parallel operation is load sharing. The total load, comprising a kW or active component and a kVAR or reactive component, must be shared by the systems with respect to their normal ratings.

The kW component is adjusted by purely mechanical means and requires relatively fine speed control of the prime mover (engine). It is advisable to fit a limited range governor to avoid large adjustments of speed when in parallel.

The kVAr component is a function of the AC generator excitation. When machines are in parallel, the magnitude of the field excitation will not directly influence the output voltage, (depending upon the relative size of the Generator to the bus-bar system) it does however, adjust the internal power factor at which a particular machine operates. For instance, an over-excited AC generator will produce a lagging pf current from that Generator. If a difference in excitation exists, then circulating currents will flow, limited only by the internal machine reactance. This current will appear as a zero p.f. leading or lagging current, depending on the machine excitation, and will either subtract or add to the total current that each machine supplies. Reactive current, either leading or lagging, is by virtue of the 90-degree phase displacement, quite commonly described as being quadrature.

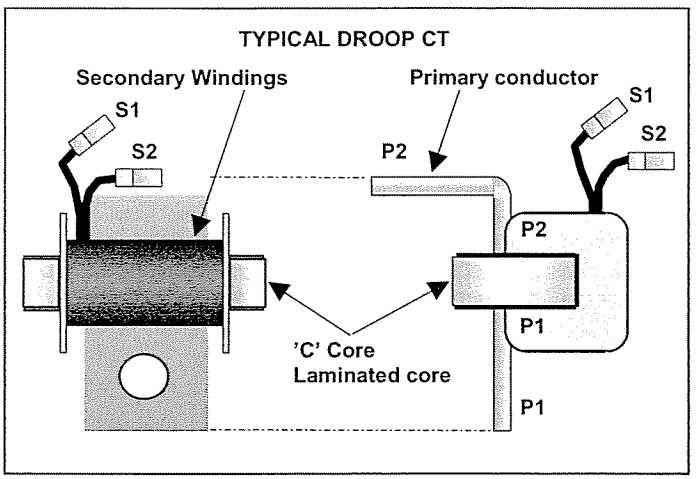
The Generators must therefore be provided with equipment to sense this reactive current, and limit it to an acceptable level. Hence the quadrature droop Current Transformer, which is connected to the AVR sensing terminals S1-S2.
Note: For correct operation, it is essential that the droop CT primary conductor is Fitted into the correct phase, (usually 'W' for 3 phase Generators), and in the correct polarity.
The secondary output leads S1 –S2, must also be connected in the correct polarity.
(Pre 1989 machines). The droop CT is connected in parallel with a burden resistor or choke, external to the AVR, and in series with the AVR sensing supply.

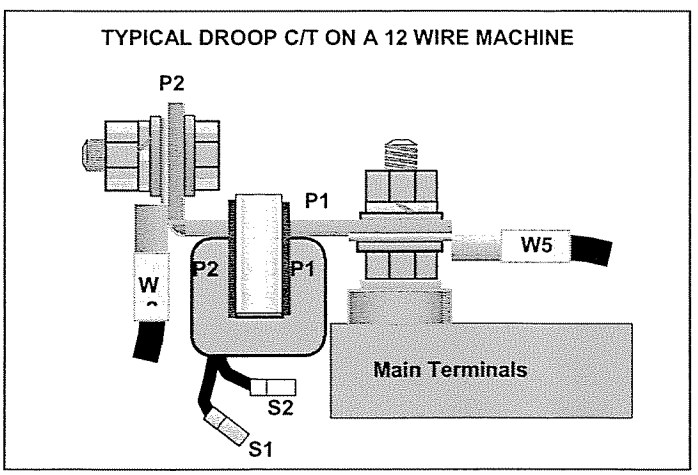
2. General notes on setting up procedure

Stable parallel operation and accurate load sharing between no load and full load can only be obtained when the initial voltage settings and droop kits are correctly set up. It is also most important the engine governor characteristics are similar otherwise incorrect kW load sharing can result when either increasing or reducing load.

To check the no load voltage settings, run each machine singly at the normal no load frequency, i.e. 52Hz for 50Hz operation or 62Hz for 60Hz operation. The rated voltages should now be set to within ½% of each other. Remote hand trimmers can be fitted to the control panel for this purpose.

Quadrature droop equipment





The most important aspect of initial setting up procedure concerns the droop circuit. Most of the troubles allied to poor parallel operation originate from the droop circuit. They are either incorrectly adjusted for the level of voltage droop, or are incorrectly connected, such that a rising voltage characteristic is obtained.
If a machine is specified for parallel operation at the time of ordering, then the droop kit supplied will have been set up on test. Provided that the terminal markings and connections are followed, no problem should result.
Caution! Reversal of the transformer or reversal of the secondary connections to the transformer will result in a rising voltage characteristic, which is completely unstable during parallel operation. In this condition very high circulating current will be produced by the generators.

Where machines have to be modified to incorporate a droop CT at a later date, ensuring a drooping voltage characteristic appears to be of the greatest difficulty. As previously stated, the droop is correctly adjusted when the terminal voltage droops 5% with zero pf, or 3% when the generator is at full load 0.8 PF.

Testing the parallel droop circuit for reversal

1. Adjust the AVR droop control to put the maximum amount of droop in circuit. (Pre 1989 machines), Move the tapping band on the burden resistor to its maximum position across the droop CT.
2. Run the machine singly at full rated speed, and apply as much inductive load (i.e. motors transformers etc.) as can be obtained.
3. Make a note of the output voltage from the machine terminals.
4. With a switch, short circuit parallel droop transformer, terminals (S1-S2), (or turn the "DROOP" adjustment on the AVR to minimum), and observe the output voltage from the machine.
5. If the voltage RISES slightly, this indicates that the droop circuit is functioning correctly, and polarity is correct.
6. If the voltage has dropped slightly, the droop transformer is reversed, and the connections of its two output leads S1 - S2 should be changed over.
7. After completion of this test, adjust the droop setting to required level.

Setting the droop circuit

The parallel droop CT is connected directly across the AVR terminals S1-S2. Droop adjustment is achieved on the AVR "DROOP" trimmer. Normal setting will be between 25% clockwise, to fully clockwise, depending upon the AVR type, and the level of droop required.
Correct droop adjustment will produce a 3% voltage drop at full load, 0.8 power factor, (as a single running Generator).
Note1: Droop is non-effective at power factor 1, (unity), therefore a power factor of 0.8 is important for correct adjustment.
Note 2: The test load can be reduced pro rata, i.e., at 50% full load 0.8 pf, Voltage droop setting would be 1.5%.
Note 3: Excessive Droop will produce poor voltage regulation from no load to full load at 0.8 pf, and will also produce larger voltage dips during motor starting. The droop should be adjusted to give satisfactory load sharing performance in parallel, without compromising voltage regulation and motor starting performance.

Checking the Droop Current Transformer output

Should problems occur with a), insufficient droop, or b), too much droop, the droop CT output should be checked.
With the droop CT connected to the AVR terminals S1-S2, apply 50% load, (any power factor), to the Generator, and check the output voltage across terminals S1–S2.
At 50% load, the output should be between 0.5 and 2.5 VAC. Voltage reading higher or lower than this indicate

that the CT current rating is incorrect for the Generator current rating.
Note: The droop trimmer setting will not affect this test.

Generators manufactured before 1989

Droop is adjusted on a burden resistor, mounted in the Generator terminal box, and can be checked across the resistor terminals.
If the voltage droop is too great on load, less resistance is required across the droop CT, on the burden resistor. Conversely, a larger droop requires more resistance. A value of between 30 and 50 ohms will give satisfactory performance.

Step by step setting up procedure for parallel operation

The following is intended as a general guide only. If any doubt exists as to the reason for various tests, further reference should be made to the preceding notes. All machines must obviously be correctly wired in accordance with the appropriate connection and wiring diagrams.

(a) Run No.1 generator on no load at rated speed. Check AC voltage and adjust where necessary.

(b) Check phase rotation of No. 1 generator.

(c) Run No. 2 generator and proceed as items a and b, voltages must be within 0.5% of No.1 generator.

(d) With Nos. 1 and 2 generators running on no load, switch in synchroscope or lights.

(e) Adjust speed until synchroscope rotates very slowly or lights slowly brighten and dim.

(f) Check finally that voltages are equal or within 0.5% of each other. Adjust as required.

(g) Close breaker at synchronism; observe ammeters for circulating current, if in excess of 5%, recheck no load voltage settings and droop circuits for polarity, (reversal of CT terminals S1-S2).

(h) Increase load until full load appears on each generator when in parallel. Some adjustment to one engine governor may be required to ensure balanced kW meter readings.

(i) Check the ammeter readings with the kW meters equal. They should be within 5% of each other.

(j) If the ammeter readings are outside 5%, first check that the meters are all accurate. The machine with the highest current is over-excited, and therefore requires more droop to compensate. Increase the droop setting.

(k) With full load on each generator reduce the load in 20% increments. At each loading, observe kW meter and ammeter readings down to 20% full load. Any variation of either instrument beyond 5% of each other requires correction.

(l) Unequal kW sharing implies a faulty prime mover, most likely the governor. Adjust kW sharing on the engine governors, and when equal, check the ammeter readings.

(m) Unequal ammeter readings at the full load end of the range imply incorrect levels of droop.

(n) Unequal ammeter readings approaching the no load condition imply incorrect voltage settings.

The most likely procedure that occurs in practice concerns the paralleling of additional machines to already loaded sets. For instance, if a set is supplying a load equal to 75% of its output and further load is anticipated, the engineer may decide to spread this load over two sets. A procedure somewhat on the lines of the following is required: -
The incoming set is started and run at no load frequency. The synchroscope / lights switch is closed, connecting the incoming machine and the busbar via the synchroscope or lights. As the incoming machine is fast, the synchroscope will rotate in the fast direction, or the lights will brighten and dim at the rate dependent of the frequency difference.

The speed of the incoming machine should be reduced by actuating the motorised governor in the slow direction.

When the frequencies are nearly equal, the speed of rotation of the synchroscope or the changes in brilliance of the lights will be slow enough to enable the set contactor to be closed when the voltages are in synchronism. This will be at twelve o'clock position on the synchroscope, or with lights bright or dim dependent on which connection is used.

Note: When synchronising the incoming generator with loaded generators, the loaded generator(s), can have a voltage level up to 4% lower than the in-coming generator. This is normal, and is due to the effect of droop, and AVR regulation. Do not adjust the voltage after the initial no-load setting. This Voltage difference is essential, in order that the incoming Generator starts to take a proportion of the reactive (kVAr), load current on breaker closure.

Load Sharing

In order that the incoming machine may now take its share of the load, the governor control should be held in the speed raise position, until the desired load is indicated by the kW meter and ammeter. Conversely, if too much load is applied holding the governor control in the speed lower position can reduce it. It is most important that the total load be shared in respect of their normal ratings and the meter readings should be compared with the name plate data. In any event, unequal load sharing requires correction to avoid mechanical problems which occur when diesel engines are run light for any considerable time.

It is important to differentiate between unbalanced loading caused simply by the operator failing to spread the load equally over the two sets, and by circulating currents unbalancing the ammeter readings.
For example: consider 2 X 100kVA generators in parallel, with no circulating currents, supplying a load of 150 kVA, at 0.8 p.f.

With the load distributed equally, meter readings would appear as follows:

Machine	VOLTS	AMP	kW	kVA	p.f.
No. 1	415	104	60	75	0.8 lag
No. 2	415	104	60	75	0.8 lag

If the load were distributed unequally, again no circulating currents, the following figures could appear:

Machine	VOLTS	AMP	kW	kVA	p.f.
No. 1	415	139	80	100	0.8 lag
No. 2	415	69	40	50	0.8 lag

If now the same unequally distributed load is being supplied, but circulating currents are present, meter readings something on the lines of the following would be observed.

Machine	VOLTS	AMP	kW	kVA	p.f.
No. 1	415	185	80	133	0.6 lag
No. 2	415	60	40	43	0.93 lead

Machine No. 1 is now supplying 133 kVA at 0.6 pf, considerably in excess of its normal rating. Continued operation under this loading would cause the AVR overload protection circuit to trip, or the main stator and the rotor to fail. Machine No. 2 is operating under-excited, that is, operating with a leading power factor, and at much reduced kVA.

This will not damage No. 2 generator, but it is evident that No. 1 generator is very heavily over-loaded. A leading power factor condition is particularly difficult to detect unless individual power factor meters are fitted. The normal instrumentation of ammeter, voltmeter and kW meter cannot indicate this load condition.

Excitation levels

As a guide to load sharing for similar generators, the D.C. excitation volts should be approximately equal when the generators are correctly sharing reactive and active current. This can be checked across the AVR terminal X+ (F1) and XX- (F2). The Generator with the highest excitation is more lagging, the lowest excitation Generator will more leading power factor.

3. Difficulties

Some paralleling problems, which can occur, are detailed below. Probable causes are also shown.

(a) Oscillating kW meter, ammeter and voltmeter.

Cause: Engine governing. Replace by known serviceable unit. This may also be caused by electronic governors with insufficient speed droop (less than 2%).

(b) Unbalanced ammeter readings. kW meters balanced and stable.

Cause: Circulating current through incorrect voltage settings, droop CT connections reversed or insufficient droop.

(c) Unbalanced ammeter readings on no load or rapidly rising currents as soon as contactor is closed.

Cause: Incorrect voltage settings or droop CT connections reversed.

(d) Unbalanced kW and ammeter readings as load increased or decreased.

Cause: Dissimilar governor speed regulation, or very tight governor control (electronic). If governor is set at less than 2% speed regulation, kW load sharing will be poor.

(e) Unbalanced ammeter readings as load increased. KW meters balanced.

Cause: Droop circuit setting not identical, or one droop kit reversed, or droop CT not in circuit.

Apart from the above problems, certain peculiarities may exist which are in no way detrimental to the operation of the sets. They may, however, confuse the operator into thinking a fault exists.

The most common query results from voltage oscillation during the initial paralleling procedure.

When an additional set is being connected to the busbars with the synchroscope / lights switch in the on position, a point may be reached where the incoming machine voltage starts to fluctuate. This only occurs when the frequency difference is at its greatest. As the frequencies approach each other, no further instability is noticed. This is not, however, a function of the stability circuit within the AVR, but relates to 'pickup' problems associated with the switchboard wiring.

4. Neutral interconnection

It should be noted that paralleling of all system neutrals can under certain circumstances lead to over heating or possible stator burnout's.
This is particularly evident when machines of dissimilar manufacture are paralleled. Differences in generated waveshape may cause large harmonic circulating currents through the neutrals.

The neutrals of dissimilar machines must, therefore, never be connected. On the other hand, neutrals of like machines may be connected.

5. Paralleling with the public supply

The Mains (Utility), Voltage can vary by as much as ± 10%, (or more in some regions). The droop equipment alone would be unable to maintain control of the resultant reactive currents.
It is therefore recommended that a Power Factor Controller (PFC3) be used, when paralleling with the Mains (Utility).
This enables the Generator to maintain a constant power factor, when the Mains (Utility), Voltage is stepped up or down by the authorities.
The Power Factor Controller (PFC3), can also be supplied with voltage matching facility, which allows the generator voltage to be adjusted automatically to match the public supply, thus reducing any switching transients on closure of the circuit breaker.
Parallel Droop is still required, working in conjunction with the PFC3, to control rapid current surges, and 'soften' the effects of sudden mains voltage stepping.
Droop is also required to control circulating currents when the Generators are required ton run in 'Island mode', (as mains failure or emergency supply), during which time the PFC3 must be switched off.

PARALLEL OPERATION FAULT FINDING CHART

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
CIRCUIT BREAKER WILL NOT CLOSE WHEN ATTEMPTING TO PARALLEL MACHINES.	a) Circuit breaker fitted with 'Check Synchronising' protection, which prevents out of phase paralleling).	a) Ensure that the synchroscope is indicating that machines are IN PHASE, or close to the eleven o'clock position, (when rotating in a clockwise direction). Ensure that the speed difference between the incoming set and the bus bar is small enough to prevent rapid rotation of the synchroscope, (or rapid fluctuations of the lights), before closing circuit breaker.
	b) Phase rotation of one machine is different to the other.	b) Check the phase rotation of each individual Generator. NO ATTEMPT TO PARALLEL must be made until the phase rotations are all identical. Reverse two phases on the Generator, which has a different rotation.
	c) Voltage difference too high between the incoming Generator and the Bus bar.	c) The voltage on the incoming set can be up to 4% higher than the bus bar Voltage. THIS IS NORMAL. Do not adjust original no-load Voltage settings. If difference is greater than 4%, check for excessive droop on the loaded Generator(s).
DIFFICULTY IN MAINTAINING A STABLE IN-PHASE CONDITION, PRIOR TO SYNCHRONISING.	a) Governor drift on one or more of the engines.	a) Let engines stabilise (warm up) before paralleling. If speed is still drifting check governors and engine condition.
	b) Load variation on the bus-bar causing speed/ frequency changes at the time of synchronising.	b) Disconnect any rapidly varying load. Check that there is no likelihood of a motor or automatic load starting when synchronisation is attempted. DO NOT attempt to parallel if the load current is highly unstable.
FREQUENCY (Hz), UNSTABLE WHEN ON LOAD IN PARALLEL.	Engine speed droop too 'tight' or cyclic irregularities (instability), between the engines. (Check kW meters for rapid shifting of kW power between sets).	Increase the engine governor speed droop, to 4% droop, (no load to full load). Check for "sticky" governors on a new engine. Check engines for cyclic problems, (firing, out of balance, etc),
VOLTAGE FLUCTUATES DURING SYNCRONISATION, (STABLE BEFORE AND AFTER)..	This symptom usually results from line pick-up between the Generators, through the synchronising panel and/or protection circuits, (earth leakage etc), that can form a temporary 'closed loop' link between the Generators during synchronisation.	The fluctuation will decay when the Generators approach synchronism, (almost identical speeds), and will disappear completely when the circuit breaker is closed. The synchronising equipment, earth leakage protection, and/or wiring circuits, in the switchboard can produce pickup problems.
CURRENT RISES RAPIDLY WITHOUT CONTROL AS INCOMING CIRCUIT BREAKER IS CLOSED.	Parallel droop equipment reversed on one of the Generators.	Check the droop CT's for reversal. (See previous text in this section). Reverse lead S1-S2 on the droop CT. Check excitation volts, the Generator with reversal will have highest excitation volts.

SYMPTOM	POSSIBLE CAUSE	TEST AND REMEDIES
CIRCULATING CURRENT ON BOTH GENERATORS AT NO LOAD, (CURRENT IS STABLE).	a) Voltage difference (excitation level) between the Generators.	a) Check Voltages at NO LOAD, (identical frequencies), and ensure all Generators have identical voltages at no load. Do not adjust when load sharing.
	b) Parallel droop equipment reversed on BOTH Generators. (Unlike ONE droop reversal, which is a highly UNSTABLE condition).	b) Check ALL droop CT's for reversal, as suggested in previous test.
	c) Incorrect setting of parallel droop equipment.	c) Check settings of droop trimmers. Check droop CT's are in correct phase. Check CT output to AVR S1-S2 is correct. (See previous text).
KILOWATT METERS SHOWING UNBALANCED READINGS.	Engines not sharing the power (kW) equally.	Adjust the Governors of one engines to equalise the kilowatt sharing.
AMMETERS SHOWING UNBALANCED READINGS AFTER ADJUSTMENT OF THE KILOWATT METERS.	a) Voltage difference (excitation levels) between the machines.	a) Test the machines individually for exact voltage at NO-LOAD.
	b) Parallel droop equipment incorrectly adjusted.	b) Adjust as stated in previous text.
	c) Improved regulation equipment affecting the load sharing. (Pre 1989 machines only.)	c) Short out the improved regulation equipment and test again. Re-adjust if this is causing the problem. Remove improved reg. equipment if AVR's are changed to a later model.
KILOWATT READINGS BECOMING UNBALANCED AS LOAD IS INCREASED OR DECREASED.	Engine governors are incompatible, or new governors 'sticking, giving unequal kW sharing over load variations.	The engine governors must be adjusted to give similar NO-LOAD/FULL LOAD characteristics. Check for 'sticky' governors on new or repainted engines. Electronic governors should be set with a minimum 2% speed droop to ensure satisfactory kilowatt load sharing. If tighter speed regulation is required, an isocronous kW load sharing system should be installed.
AMMETER READINGS BECOME MORE UNBALANCED AS LOAD IS INCREASED.	a) Difference in Parallel droop level settings.	Run Generators SINGLY, and apply load at approximately 25%, 50% & 100%. Take Voltage readings at each level and compare them with the other Generators. Adjust control systems to remove regulation differences. Repeat the above with as much inductive load as possible i.e. motors, transformers etc. Adjust the parallel droop trimmers, to achieve equal inductive load sharing.
	b) Difference in no load to full load voltage regulation of AVR's.	
	These settings are the major contributing factors to the load/voltage characteristics of the machine, and therefore must be set to give equal characteristics to the machines with which it is paralleled.	
VOLTAGE REGULATION POOR AS A SINGLE RUNNING MACHINE.	Excess amount of parallel droop in circuit.	For normal voltage regulation as a single running machine, a shorting switch should be fitted across the parallel droop transformer. (S!-S2). This should be clearly marked 'Single' 'Parallel' operation. (See previous text).
kW METERS UNSTABLE, ENGINES 'ROCKING' ON THEIR MOUNTS.	Electronic engine governor speed 'droop' characteristics set too tight.	At least 2% engine droop is essential for kW (Active current) sharing. If 1% or less speed regulation is required, isocronous governing and kW load sharing system.

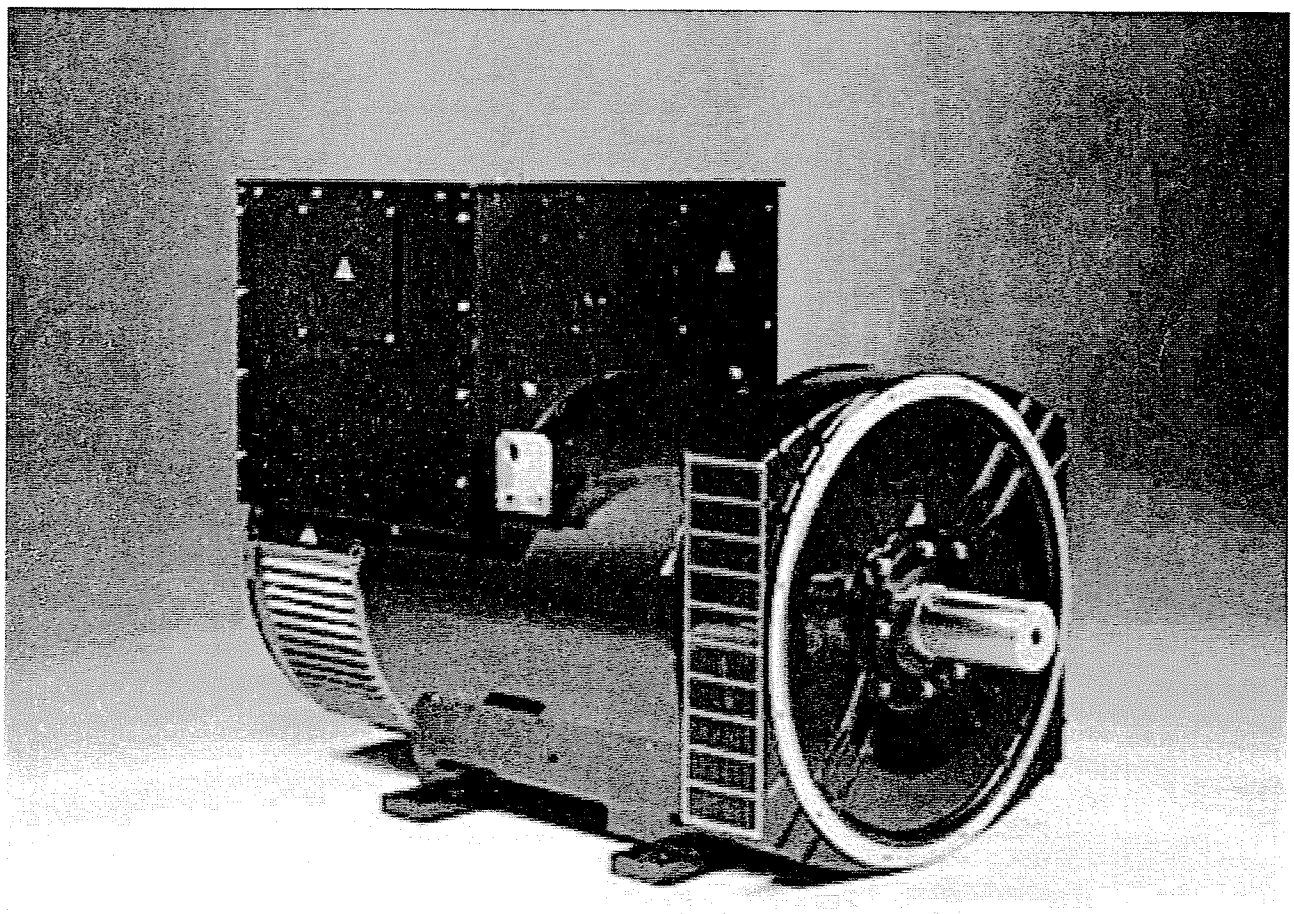
AC GENERATORS FROM
NEWAGE INTERNATIONAL



Installation, Service & Maintenance Manual

for AC generators with the following prefixes:

HCI; HCM; HCK 4,5,6,7.

SAFETY PRECAUTIONS

Before operating the generating set, read the generating set operation manual and this generator manual and become familiar with it and the equipment.

SAFE AND EFFICIENT OPERATION CAN ONLY BE ACHIEVED IF THE EQUIPMENT IS CORRECTLY OPERATED AND MAINTAINED.

Many accidents occur because of failure to follow fundamental rules and precautions.

ELECTRICAL SHOCK CAN CAUSE SEVERE PERSONAL INJURY OR DEATH.

Observe all **WARNING/CAUTION** notices.

- Ensure installation meets all applicable safety and local electrical codes. Have all installations performed by a qualified electrician.
- Do not operate the generator with protective covers, access covers or terminal box covers removed.
- Disable engine starting circuits before carrying out maintenance.
- Disable closing circuits and/or place warning notices on any circuit breakers normally used for connection to the mains or other generators, to avoid accidental closure.

Observe all **IMPORTANT, CAUTION, WARNING, and DANGER** notices, defined as:

Important ! **Important refers to hazard or unsafe method or practice which can result in product damage or related equipment damage.**

Caution ! **Caution refers to hazard or unsafe method or practice which can result in product damage or personal injury.**

Warning !

Warning refers to a hazard or unsafe method or practice which CAN result in severe personal injury or possible death.

Danger !

Danger refers to immediate hazards which WILL result in severe personal injury or death.

Due to our policy of continuous improvement, details in this manual which were correct at time of printing, may now be due for amendment. Information included must therefore not be regarded as binding.

Front Cover Photograph
This photograph is representative only. Several variations are available within the range of generators covered by this manual.

FOREWORD

The function of this book is to provide the user of the Stamford generator with an understanding of the principles of operation, the criteria for which the generator has been designed, and the installation and maintenance procedures. Specific areas where the lack of care or use of incorrect procedures could lead to equipment damage and/or personal injury are highlighted, with **WARNING** and/or **CAUTION** notes, and it is important that the contents of this book are read and understood before proceeding to fit or use the generator.

The Service, Sales and technical staff of Newage International are always ready to assist and reference to the company for advice is welcomed.

Warning !

Incorrect installation, operation, servicing or replacement of parts can result in severe personal injury or death, and/or equipment damage.
Service personnel must be qualified to perform electrical and mechanical service.

EC DECLARATION OF INCORPORATION

All Stamford generators are supplied with a declaration of incorporation for the relevant EC legislation, typically in the form of a label as below.

EC DECLARATION OF INCORPORATION

IN ACCORDANCE WITH THE SUPPLY OF MACHINERY (SAFETY) REGULATIONS 1992 AND THE SUPPLY OF MACHINERY (SAFETY) (AMENDMENT) REGULATIONS 1994 IMPLEMENTING THE EC MACHINERY DIRECTIVE 89/392/EEC AS AMENDED BY 91/368/EEC.

THIS **STAMFORD A.C. GENERATOR** WAS MANUFACTURED BY OR ON BEHALF OF
NEWAGE INTERNATIONAL LTD
BARNACK ROAD STAMFORD LINCOLNSHIRE ENGLAND.

THIS COMPONENT MACHINERY MUST NOT BE PUT INTO SERVICE UNTIL THE MACHINERY INTO WHICH IT IS TO BE INCORPORATED HAS BEEN DECLARED IN CONFORMITY WITH THE PROVISIONS OF THE SUPPLY OF MACHINERY (SAFETY) REGULATIONS 1995/MACHINERY DIRECTIVE.

FOR AND ON BEHALF OF NEWAGE INTERNATIONAL LIMITED

NAME: **LAWRENCE HAYDOCK**
POSITION: **TECHNICAL DIRECTOR**
SIGNATURE:

THIS COMPONENT MACHINERY CARRIES THE CE MARK FOR COMPLIANCE WITH THE STATUTORY REQUIREMENTS FOR THE IMPLEMENTATION OF THE FOLLOWING DIRECTIVES

The EMC Directive 89/336/EEC
WARNING! This Component Machinery shall not be used in the Residential, Commercial and Light Industrial environment unless it also conforms to the relevant standard (EN 50081 - 1) REFER TO FACTORY FOR DETAILS

ii) The Low Voltage Directive 73/23/EEC as amended by 93/68/EEC

CE

ELECTROMAGNETIC COMPATIBILITY

Additional Information

European Union
Council Directive 89/336/EEC

For installations within the European Union, electrical products must meet the requirements of the above directive, and Newage ac generators are supplied on the basis that:

- They are to be used for power-generation or related function.
- They are to be applied in one of the following environments:

  Portable (open construction - temporary site supply)
  Portable (enclosed - temporary site supply)
  Containerised (temporary or permanent site supply)
  Ship-borne below decks (marine auxiliary power)
  Commercial vehicle (road transport / refrigeration etc)
  Rail transport (auxiliary power)
  Industrial vehicle (earthmoving, cranes etc)
  Fixed installation (industrial - factory / process plant)
  Fixed installation (residential, commercial and light industrial - home / office / health)
  Energy management (Combined heat and power and/or peak lopping)
  Alternative energy schemes

- The standard generators are designed to meet the 'industrial' emissions and immunity standards. Where the generator is required to meet the residential, commercial and light industrial emissions and immunity standards reference should be made to Newage document reference N4/X/011, as additional equipment may be required.
- The installation earthing scheme involves connection of the generator frame to the site protective earth conductor using a minimum practical lead length.
- Maintenance and servicing with anything other than factory supplied or authorised parts will invalidate any Newage liability for EMC compliance.
- Installation, maintenance and servicing is carried out by adequately trained personnel fully aware of the requirements of the relevant EC directives

Katolight Service - Master Repair Manual - Page 985

SECTION 1

INTRODUCTION

1.1 INTRODUCTION

The HC range of generators is of brushless rotating field design, available up to 660V at 50 Hz or 60 Hz and built to meet BS5000 Part 3 and international standards.

1500 rpm (50Hz) or 1800 rpm (60Hz) 4 pole generators are available from 200kW to 2000kW in four frame sizes - HC4, HC5, HC6 and HC7.

1000 rpm (50Hz) or 1200 rpm (60Hz) 6 pole generators are available from 224kW to 1300kW in two frame sizes - HC6 and HC7.

Frame sizes HC4 and HC5 may be provided with a stator fed excitation system using SX440 or SX421 AVR, or with the permanent magnet generator (PMG) powered excitation system, using the MX341 or MX321 AVR.

Frames HC6 and HC7 are fitted with the PMG system using the MX321 AVR.

CORE LENGTH

NUMBER OF BEARINGS 1 OR 2

1.3 SERIAL NUMBER LOCATION

Each generator has its unique serial number stamped in to the upper section of the drive end frame end-ring.

Inside the terminal box two adhesive rectangular labels have been fixed, each carrying the generators unique identity number. One label has been fixed to the inside of the terminal box sheet metal work, and the second label fixed to the main frame of the generator.

1.4 RATING PLATE AND CE MARK

The generator has been supplied with a self adhesive rating plate label to enable fitting after final assembly and painting. It is intended that this label will be stuck to the outside of the non drive end of the terminal box.

A CE Mark label is also supplied loose for fitment after final assembly and painting. This should be attached to an external surface of the Generator at a suitable location where it will not be obscured by the customer's wiring or other fittings. Before fitting the CE Mark label the genset builder must address the requirements of the relevant EC legislation to ensure the compliance of the genset as a whole. CE compliance will also need to be addressed when installed on site.

The surface in the area where a label is to be stuck must be flat, clean, and any paint finish be fully dry before attempting to attach label. Recommended method for attaching label is peel and fold back sufficient of the backing paper to expose some 20 mm of label adhesive along the edge which is to be located against the sheet metal protrusions. Once this first section of label has been carefully located and stuck into position the backing paper can be progressively removed, as the label is pressed down into position. The adhesive will achieve a permanent bond in 24 hours.

SECTION 2

PRINCIPLE OF OPERATION

2.1 SELF-EXCITED AVR CONTROLLED GENERATORS

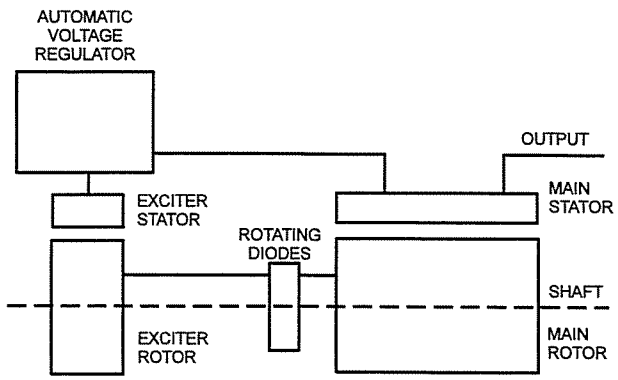

Fig. 1

The main stator provides power for excitation of the exciter field via the SX440 (or SX421) AVR which is the controlling device governing the level of excitation provided to the exciter field. The AVR responds to a voltage sensing signal derived from the main stator winding. By controlling the low power of the exciter field, control of the high power requirement of the main field is achieved through the rectified output of the exciter armature.

The SX440 AVR senses average voltage on two phases ensuring close regulation. In addition it detects engine speed and provides voltage fall off with speed, below a pre-selected speed (Hz) setting, preventing over-excitation at low engine speeds and softening the effect of load switching to relieve the burden on the engine.

The SX421 AVR in addition to the SX440 features has three phase rms sensing and also provides for over voltage protection when used in conjunction with an external circuit breaker (switchboard mounted).

2.2 PERMANENT MAGNET GENERATOR (PMG) EXCITED - AVR CONTROLLED GENERATORS

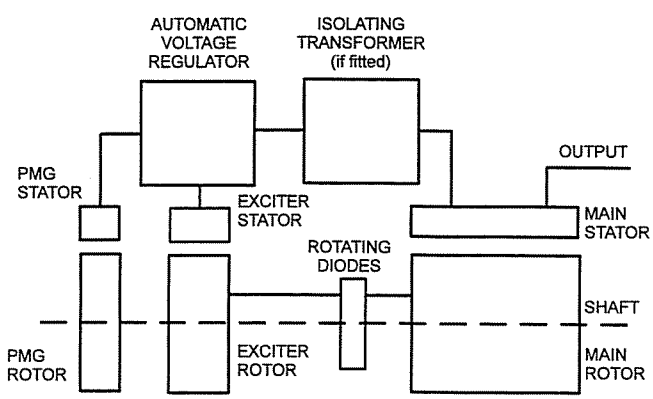

Fig. 2

The permanent magnet generator (PMG) provides power for excitation of the exciter field via the AVR MX341 (or MX321) which is the controlling device governing the level of excitation provided to the exciter field. The AVR responds to a voltage sensing signal derived, via an isolating transformer in the case of MX321 AVR, from the main stator winding. By controlling the low power of the exciter field, control of the high power requirement of the main field is achieved through the rectified output of the exciter armature.

The PMG system provides a constant source of excitation power irrespective of main stator loading and provides high motor starting capability as well as immunity to waveform distortion on the main stator output created by non linear loads, e.g. thyristor controlled dc motor.

The MX341 AVR senses average voltage on two phases ensuring close regulation. In addition it detects engine speed and provides an adjustable voltage fall off with speed, below a pre-selected speed (Hz) setting, preventing over-excitation at low engine speeds and softening the effect of load switching to relieve the burden on the engine. It also provides over-excitation protection which acts following a time delay, to de-excite the generator in the event of excessive exciter field voltage.

The MX321 provides the protection and engine relief features of the MX341 and additionally incorporates 3 phase rms sensing and over-voltage protection.

The detailed function of all the AVR circuits is covered in the load testing section (subsection 4.7).

2.3 AVR ACCESSORIES

The SX440, SX421, MX341 and MX321 AVRs incorporate circuits which, when used in conjunction with accessories, can provide for parallel operation either with 'droop' or 'astatic' control, VAR/PF control and in the case of the MX321 AVR, short circuit current limiting.

Function and adjustment of the accessories which can be fitted inside the generator terminal box are covered in the accessories section of this book.

Separate instructions are provided with other accessories available for control panel mounting.

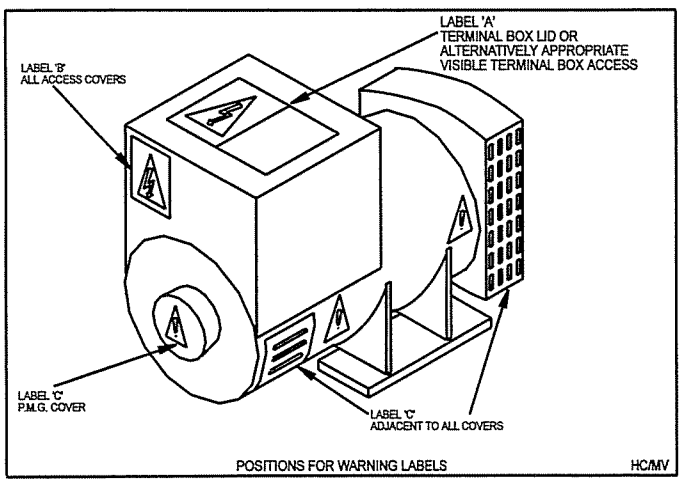
Katolight Service - Master Repair Manual - Page 987

SECTION 3

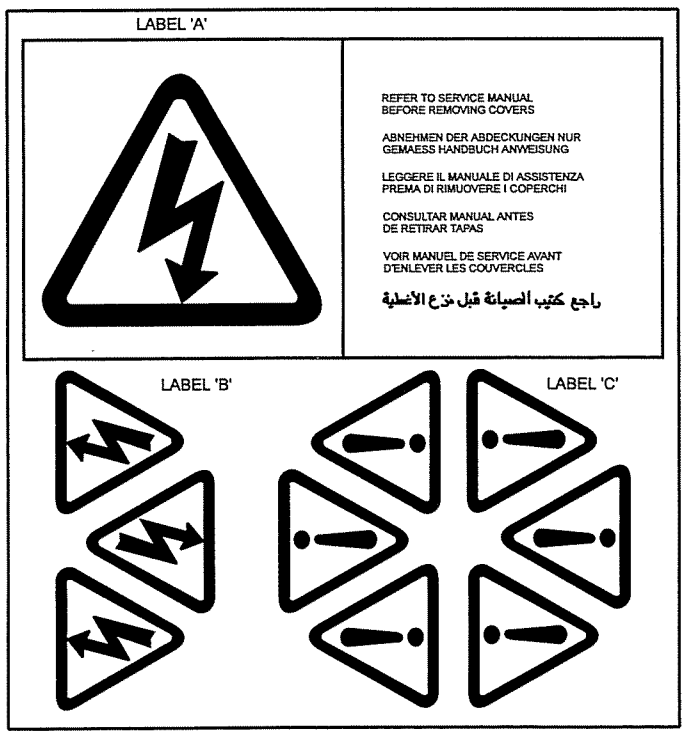
APPLICATION OF THE GENERATOR

The generator is supplied as a component part for installation in a generating set. It is not, therefore, practicable to fit all the necessary warning/hazard labels during generator manufacture. The additional labels required are packaged with this Manual, together with a drawing identifying their locations. (see below).

It is the responsibility of the generating set manufacturer to ensure that the correct labels are fitted, and are clearly visible.



POSITIONS FOR WARNING LABELS HC/MV



The generators have been designed for use in a maximum ambient temperature of 40°C, and altitude less than 1000 metres above sea level in accordance with BS5000.

Ambients in excess of 40°C, and altitudes above 1000 metres can be tolerated with reduced ratings - refer to the generator nameplate for rating and ambient.

In the event that the generator is required to operate in an ambient in excess of the nameplate value or at altitudes in excess of 1000 metres above sea level, refer to the factory.

The generators are of air-ventilated screen protected drip-proof design and are not suitable for mounting outdoors unless adequately protected by the use of canopies. Anti-condensation heaters are recommended during storage and for standby duty to ensure winding insulation is maintained in good condition.

When installed in a closed canopy it must be ensured that the ambient temperature of the cooling air to the generator does not exceed that for which the generator has been rated.

The canopy should be designed such that the engine air intake to the canopy is separated from the generator intake, particularly where the radiator cooling fan is required to draw air into the canopy. In addition the generator air intake to the canopy should be designed such that the ingress of moisture is prohibited, preferably by use of a two stage filter.

The air intake/outlet must be suitable for the air flow given in the following table with additional pressure drops less than or equal to those given below:

Frame	Air Flow		Additional (intake/outlet) Pressure Drop
	50Hz 1500 Rev/Min	60Hz 1800 Rev/Min	
HC4	0.48m³/sec	0.58m³/sec	6mm water gauge
	1030cfm	1240cfm	(0.25")
HCK4	0.68m³/sec	0.83m³/sec	6mm water gauge
	1450cfm	1760cfm	(0.25")
HC5	1.04m³/sec	1.31m³/sec	6mm water gauge
	2202cfm	2708cfm	(0.25")
HCK5	1.23m³/sec	1.59m³/sec	6mm water gauge
	2615cfm	3366cfm	(0.25")
HC6	1.62m³/sec	1.96m/sec	6mm water gauge
	3420cfm	4156cfm	(0.25")
HC7	2.64m³/sec	3.17m³/sec	6mm water gauge
	5600cfm	6720cfm	(0.25")
HCK7	3.0m³/sec	3.70m³/sec	6mm water gauge
	6550cfm	7860cfm	(0.25")

Table 1

If specified at the time of ordering, HC6 and HC7 generators may be fitted with air filters. Air filters can be supplied factory fitted or as parts for up-fit for the HC4 and HC5 generators. These are oil charged gauze filters and require charging during installation.

Important ! Reduction in cooling air flow or inadequate protection to the generator can result in damage and/or failure of windings.

Dynamic balancing of the generator rotor assembly has been carried out during manufacture in accordance with BS 6861 Part 1 Grade 2.5 to ensure vibration limits of the generator are in accordance with BS 4999 Part 142.

The main vibration frequencies produced by the component generator are as follows:-:

4 pole	1500 rpm	25 Hz
	1800 rpm	30 Hz
6 pole	1000 rpm	16.7 Hz
	1200 rpm	20 Hz

3.1 VIBRATION

Vibrations generated by the engine are complex and contain harmonics of 1.5, 3, 5 or more times the fundamental frequency of vibration. The generator will be subjected to this vibration, which will result in the generator being subjected to vibration levels higher than those derived from the generator itself.
Newage generators are designed to withstand the vibration levels encountered on generating sets built to meet the requirements of ISO 8528-9 and BS5000-3. (Where ISO 8528 is taken to be broad band measurements and BS5000 refers to the predominant frequency of any vibrations on the generating set.)

DEFINITION OF BS5000 - 3

Generators shall be capable of continuously withstanding linear vibration levels with amplitudes of 0.25mm between 5Hz and 8Hz and velocities of 9.0mm/s rms between 8 Hz and 200 Hz when measured at any point directly on the carcass or main frame of the machine. These limits refer only to the predominant frequency of vibration of any complex waveform.

DEFINITION OF ISO 8528 - 9

ISO 8528-9 refers to a broad band of frequencies, the broad band is taken to be between 2 Hertz and 300 Hertz. The table below is an example from ISO 8528 - 9 (value 1). This simplified table lists the vibration limits by kVA range and speed for acceptable genset operation.

VIBRATION LEVELS AS MEASURED ON THE GENERATOR				
Engine Speed Min $^{-1}$	SET OUTPUT kVA	VIBRATION DISPLACEMENT mm (rms)	VIBRATION VELOCITY mm/s (rms)	VIBRATION ACCELERATION m/s^2 (rms)
4 POLE 1500 rpm 50 Hz 1800 rpm 60 HZ	≤ 10 kVA	-	-	-
	> 10 but ≤ 50 Kva	0.64	40	25
	> 50 but ≤ 125 kVA	0.4	25	16
	> 125 but ≤ 250 kVA	0.4	25	16
	> 250 kVA	0.32	20	13
6 POLE 1000 rpm 50 Hz 1200 rpm 60 Hz	≥ 250 but ≤ 1250	0.32	20	13
	> 1250	0.29	18	11
The 'Broad band' is taken as 2 Hz - 300 Hz.				

Table 2

It is the responsibility of the generating set designer to ensure the alignment of the genset, stiffness of the bedframe and mountings are such that the vibration limits as defined above are met.

If the vibration levels of the generating set are not within the parameters quoted above :-

1. Consult the genset builder. The genset builder should address the genset design to reduce the vibration levels as much as possible.

2. Discuss, with Newage, the impact of not meeting the above levels on both bearing and generator life expectancy.

Important ! **Exceeding either of the above specifications will have a detrimental effect on the generating set and in particular on the life of the bearings. (See section on bearings). This will invalidate the generator warranty. If you are in any doubt, contact Newage International Limited.**

In standby applications where the running time is limited and reduced life expectancy is accepted, higher levels than specified in BS5000 can be tolerated, up to a maximum of 18mm/sec.

Two bearing generators require a substantial bedplate with engine/generator mounting pads to ensure a good base for accurate alignment. Close coupling of engine to generator can increase the overall rigidity of the set. A flexible coupling, designed to suit the specific engine/generator combination, is recommended to minimise torsional effects.

Alignment of single bearing generators is critical and vibration can occur due to the flexing of the flanges between the engine and generator. A substantial bedplate with engine/generator mounting pads is required.

For the purposes of establishing set design the bending moment at the engine flywheel housing to generator adaptor interface should not exceed that given in the table below:-

FRAME	BENDING MOMENT
4/5	140 kgm. (1000ft.lbs.)
6/7	275 kgm. (2000ft.lbs.)

The maximum bending moment of the engine flange must be checked with the engine manufacturer.

Torsional vibrations occur in all engine-driven shaft systems and may be of a magnitude to cause damage at certain critical speeds. It is therefore necessary to consider the torsional vibration effect on the generator shaft and couplings.

It is the responsibility of the generator set manufacturer to ensure compatibility, and for this purpose drawings showing the shaft dimensions and rotor inertias are available for customers to forward to the engine supplier. In the case of single bearing generators coupling details are included.

Important ! **Torsional incompatibility and/or excessive vibration levels can cause damage or failure of generator and/or engine components.**

The standard terminal box is arranged for cable entry on the right hand side looking from the non drive end of the generator. If specified at the time of order cable entry may be arranged on the opposite side.

The terminal box is constructed with removable panels for easy adaptation to suit specific glanding requirements. Within the terminal box there are insulated terminals for line and neutral connections and provision for earthing. Additional earthing points are provided on the generator feet.

Warning ! **No earth connections are made on the generator and reference to site regulations for earthing must be made. Incorrect earthing or protection arrangements can result in personal injury or death.**

The neutral is NOT connected to the frame.

Fault current curves (decrement curves), together with generator reactance data, are available on request to assist the system designer to select circuit breakers, calculate fault currents and ensure discrimination within the load network.

Warning ! **Incorrect installation, service or replacement of parts can result in severe personal injury or death, and/or equipment damage. Service personnel must be qualified to perform electrical and mechanical service.**

Katolight Service - Master Repair Manual - Page 989

SECTION 4

INSTALLATION - PART 1

4.1 LIFTING

Warning ! **Incorrect lifting or inadequate lifting capacity can result in severe personal injury or equipment damage. MINIMUM LIFTING CAPACITY REQUIRED IS AS INDICATED ON THE LIFTING LABEL. Generator lifting lugs should not be used for lifting the complete generating set.**

Two lifting lugs are provided for use with a shackle and pin type lifting aid. A spreader with chains to ensure that the lift is vertical of suitable length and lifting capacity must be used. Lifting points are designed to position the craneage point as close to the centre of gravity of the generator as possible, but due to design restrictions it is not possible to guarantee that the generator frame will remain horizontal while lifting. Care is therefore needed to avoid personal injury or equipment damage. The correct lifting arrangement is shown on the label attached to the lifting lug. (See sample below).

IMPORTANT

REFER TO SERVICE MANUAL BEFORE REMOVING COVERS. IT IS THE GENERATOR SET MANUFACTURER'S RESPONSIBILITY TO FIT THE SELF ADHESIVE WARNING LABELS SUPPLIED WITH THE GENERATOR. THE LABEL SHEET CAN BE FOUND WITH THE INSTRUCTION BOOK.

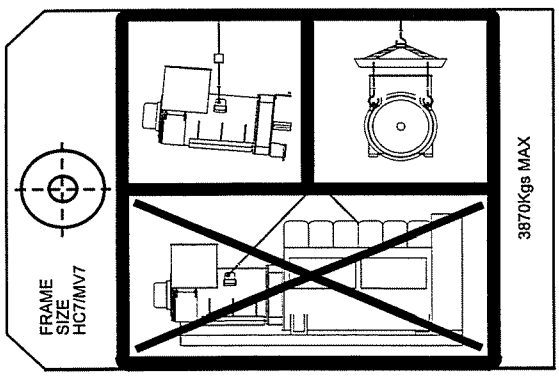


Fig. 3

Single bearing generators are supplied fitted with a rotor retaining bar at the drive end of the shaft. Single bearing generators are also fitted with wooden wedges supporting the fan for transit purposes.

Once the bar is removed to couple the rotor to engine, the rotor is free to move in the frame, and care is needed during coupling and alignment to ensure the frame is kept in the horizontal plane.

4.2 ENGINE TO GENERATOR COUPLING ASSEMBLY

During the assembly of the Generator to the Engine it will be necessary to firstly carefully align, then rotate, the combined Generator rotor - Engine crankshaft assembly, as part of the construction process, to allow location, insertion and tightening of the coupling bolts. This requirement to rotate the combined assemblies exists for both single and two bearing units.

During the construction of single bearing units it is necessary to align the generator's coupling holes with the engine flywheel holes: it is suggested that two diametrically opposite location dowel pins are fitted to the engine flywheel, over which the generator coupling can slide into final location into the engine flywheel spigot recess. The dowels must be removed and replaced by coupling bolts before the final bolt tightening sequence.

While fitting and tightening the coupling bolts it will be necessary to rotate the Engine crankshaft - Generator rotor assembly. Care should be taken to ensure that rotation is carried out in an approved manner that ensures safe working practice when reaching inside the machine to insert or tighten coupling bolts, and that no component of the assembly is damaged by non-approved methods of assembly rotation.

Engine Manufacturers have available a proprietary tool designed to enable manual rotation of the crankshaft assembly. This tool must always be used, having been engineered as an approved method of assembly rotation, by engaging the manually driven pinion with the engine flywheel starter ring-gear.

Danger ! **Before working inside the generator, during the aligning and fitting of coupling bolts, care should be taken to lock the assembly to ensure there is no possibility of assembly rotational movement.**

4.2.1 TWO BEARING GENERATORS

A flexible coupling should be fitted and aligned in accordance with the coupling manufacturer's instruction.

If a close coupling adaptor is used the alignment of machined faces must be checked by offering the generator up to the engine. Shim the generator feet if necessary. Ensure adaptor guards are fitted after generator/engine assembly is complete. Open coupled sets require a suitable guard, to be provided by the set builder.

Axial loading of the generator bearings should be avoided. Should it be unavoidable contact the factory for advice.

Caution ! **Incorrect guarding and/or generator alignment can result in personal injury and/or equipment damage.**

4.2.2 SINGLE BEARING GENERATORS TYPES HC & HCK

For transit and storage purposes the generator frame spigot and rotor coupling plates have been coated with a rust preventative. This MUST BE removed before assembly to engine.

A practical method for removal of this coating is to clean the mating surface areas with a de-greasing agent based on a petroleum solvent.

Caution ! **Care should be taken not to allow any cleaning agent to come into prolonged contact with skin.**

Alignment of single bearing generators is critical. If necessary shim the generator feet to ensure alignment of the machined surfaces.

The sequence of assembly to the engine should generally be as follows:

1. On the engine check the distance from the coupling mating face on the flywheel to the flywheel housing mating face. This should be within 0.5mm of nominal dimension. This is necessary to ensure that a thrust is not applied to the ac generator bearing or engine bearing.

2. Check that the bolts securing the flexible plates to the coupling hub are tight and locked into position. Refer to Section 7, subsection 7.5.3.4 for tightening torques.

3. Remove covers from the drive end of the generator to gain access to coupling and adaptor bolts. Check coupling joint interfaces are clean and lubricant free.

4. **TYPE HC GENERATORS**

   Check that coupling discs are concentric with adaptor spigot. This can be adjusted by the use of tapered wooden wedges between the fan and adaptor. Alternatively the rotor can be suspended by means of a rope sling through the adaptor opening.

   Offer the generator to engine and engage both coupling discs and housing spigots at same time, pushing generator towards engine until coupling discs are against flywheel face, and housing spigots located.

   TYPE HCK GENERATORS

   Screw the two supplied location studs into diametrically opposite engine flywheel tapped holes, about the horizontal centre line. Offer the generator to engine, locating rotor coupling discs over the location studs, pushing generator towards engine until housing spigots locate and coupling discs are against flywheel face.

5. Fit housing and coupling bolts taking care to use heavy gauge washers between coupling bolt head and coupling disc. Tighten bolts evenly around assembly sufficiently to ensure correct alignment.

   TYPE HCK GENERATORS

   Remove location studs and replace with coupling-flywheel bolts.

6. Tighten housing bolts.

7. Tighten coupling disc to flywheel bolts. Refer to engine manufacturers manual for correct tightening torque.

8. **TYPE HC GENERATORS**

   Remove rotor aligning aids, either wooden wedges, or the two M10 set screws and sheet metal wear plates.

Caution ! **Incorrect guarding and/or generator alignment can result in personal injury and/or equipment damage.**

4.3 EARTHING

The generator frame should be solidly bonded to the generating set bedplate. If antivibration mounts are fitted between the generator frame and its bedplate a suitably rated earth conductor (normally one half of the cross sectional area of the main line cables) should bridge across the antivibration mount.

Warning ! **Refer to local regulations to ensure that the correct earthing procedure has been followed.**

4.4 PRE-RUNNING CHECKS

4.4.1 INSULATION CHECK

Insulation tests should be carried out before running the generating set, both after assembly and after installation on site. (see Section 7.1).

Important ! **The windings have been H.V. tested during manufacture and further H.V. testing may degrade the insulation with consequent reduction in operating life. Should it be necessary to demonstrate H.V. testing, for customer acceptance, the tests must be carried out at reduced voltage levels i.e. Test Voltage= 0.8 (2 X Rated Voltage + 1000)**

4.4.2 DIRECTION OF ROTATION

4.4.2.1 FAN TYPES.

TYPE HC 4 & 5 GENERATORS.

These machines are fitted with a radial bladed bi-directional fan, operating within a conventional full height air outlet grills.

TYPE HC 6 & 7 GENERATORS.

These machines are fitted with an inclined bladed fan , operating within a conventional full height air outlet grills.

TYPE HCK 4, 5, & 7 GENERATORS.

These machines are fitted with a inclined bladed fan, operating within a voluted drive end adaptor with outlet grills half thee machine height . Designed to optimise the fans performance.

4.4.2.2 DIRECTION OF ROTATION

TYPE HCK GENERATORS.

These machines have been designed with an improved cooling fan system, incorporating the voluted fan housing. Therefore these machines are suitable only for clockwise rotation, as viewed from the drive end.

TYPE HC GENERATORS.

These machines can be operated in either direction of rotation.

Phase Rotation

HC generators can rotate efficiently in either direction. However phase rotation is fixed for clockwise rotation as viewed from the drive end. If the generator is to be rotated in a counter-clockwise direction it will be necessary for the customers to adjust their cabling to the output terminals accordingly. Refer to the factory for a reverse wiring diagram.

4.4.3 VOLTAGE AND FREQUENCY

Check that the voltage and frequency levels required for the generating set application are as indicated on the generator nameplate.

HC4/5 generators normally have a 12 ends out reconnectable winding. If it is necessary to reconnect the stator for the voltage required, refer to diagrams in the back of this manual.

4.4.4 AVR SETTINGS

To make AVR selections and adjustments remove the AVR cover and refer to 4.4.4.1, 4.4.4.2, 4.4.4.3 or 4.4.4.4 depending upon type of AVR fitted. Reference to the generator nameplate will indicate AVR type (SX440, SX421, MX341 or MX321).

Most of the AVR adjustments are factory set in positions which will give satisfactory performance during initial running tests. Subsequent adjustment may be required to achieve optimum performance of the set under operating conditions. Refer to 'Load Testing' section for details.

4.4.4.1 TYPE SX440 AVR

The following 'jumper' connections on the AVR should be checked to ensure they are correctly set for the generating set application.

Refer to Fig. 4a for location of selection links.

1. Frequency selection terminals

50Hz operation	LINK C-50
60Hz operation	LINK C-60

2. Stability selection terminals

Frame HC4/5	LINK B-C
Frame HC6/7	LINK A-B

3. Sensing selection terminals

	LINK 2-3
	LINK 4-5
	LINK 6-7

4. Excitation Interruption Link

LINK K1-K2

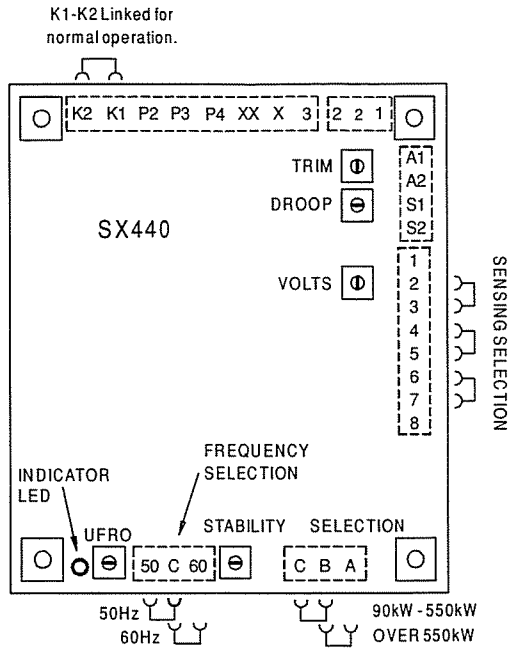

Fig. 4a

4.4.4.2 TYPE SX421 AVR

The following 'jumper' connections on the AVR should be checked to ensure they are correctly set for the generating set application.

Refer to Fig. 4b for location of selection links.

1.Frequency selection terminals

50Hz operation	LINK C-50
60Hz operation	LINK C-60

2.Stability selection terminals

Frame HC4/5	LINK B-C
Frame HC6/7	LINK A-B

3. Excitation Interruption Link

Linked at auxiliary terminal block. K1-K2

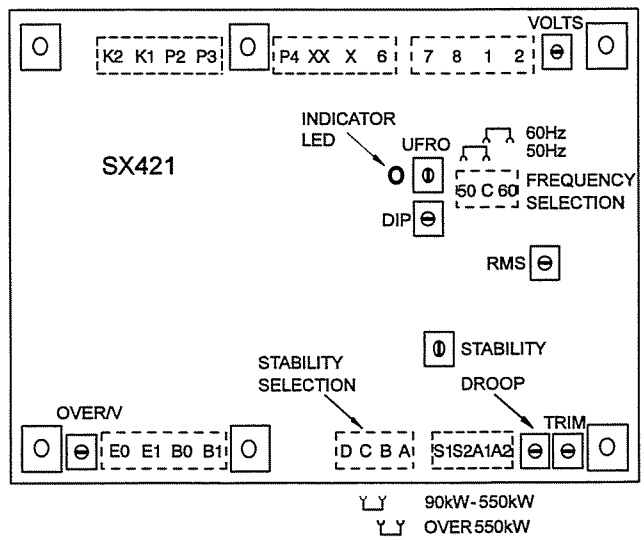

Fig. 4b

4.4.4.3 TYPE MX341 AVR

The following 'jumper' connections on the AVR should be checked to ensure they are correctly set for the generating set application.

Refer to Fig. 4c for location of selection links.

4 pole	50Hz operation	LINK 2-3
4 pole	60Hz operation	LINK 1-3
6 pole	50Hz operation	NO LINK
6 pole	60Hz operation	LINK 1-2

2. Stability selection terminals

Frame HC4/5	LINK B-C
Frame HC6/7	LINK A-B

3. Sensing selection terminals

	LINK 2-3
	LINK 4-5
	LINK 6-7

4. Excitation Interruption Link

LINK K1-K2

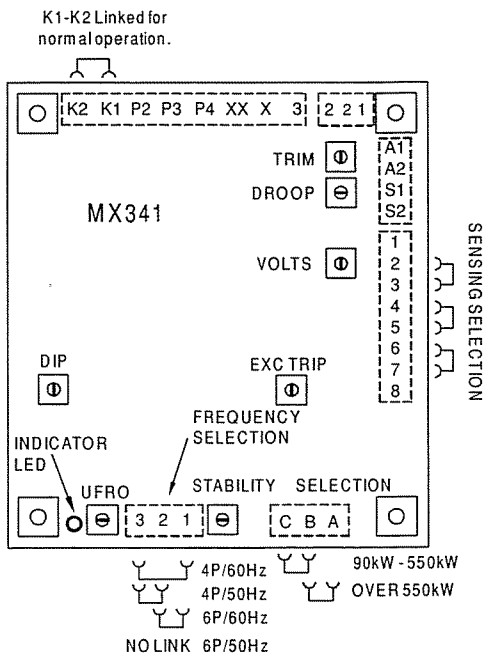

Fig. 4c

4.4.4.4 TYPE MX321 AVR

The following 'jumper' connections on the AVR should be checked to ensure they are correctly set for the generating set application.

Refer to Fig. 4d for location of selection links.

1. Frequency selection terminals

4 pole	50Hz operation	LINK 2-3
4 pole	60Hz operation	LINK 1-3
6 pole	50Hz operation	NO LINK
6 pole	60Hz operation	LINK 1-2

4.5 GENERATOR SET TESTING

Warning ! **During testing it may be necessary to remove covers to adjust controls exposing 'live' terminals or components. Only personnel qualified to perform electrical service should carry out testing and/or adjustments.**

4.5.1 TEST METERING/CABLING

Connect any instrument wiring and cabling required for initial test purposes with permanent or spring-clip type connectors.

Minimum instrumentation for testing should be line - line or line to neutral voltmeter, Hz meter, load current metering and kW meter. If reactive load is used a power factor meter is desirable.

Important ! **When fitting power cables for load testing purposes, ensure cable voltage rating is at least equal to the generator rated voltage. The load cable termination should be placed on top of the winding lead termination and clamped between the two nuts provided, on HC4/5 generators.**

Caution ! **Check that all wiring terminations for internal or external wiring are secure, and fit all terminal box covers and guards. Failure to secure wiring and/or covers may result in personal injury and/or equipment failure.**

4.6 INITIAL START-UP

Warning ! **During testing it may be necessary to remove covers to adjust controls exposing 'live' terminals or components. Only personnel qualified to perform electrical service should carry out testing and/or adjustments. Refit all access covers after adjustments are completed.**

On completion of generating set assembly and before starting the generating set ensure that all engine manufacturer's pre-running procedures have been completed, and that adjustment of the engine governor is such that the generator will not be subjected to speeds in excess of 125% of the rated speed.

Important ! **Overspeeding of the generator during initial setting of the speed governor can result in damage to the generator rotating components.**

In addition remove the AVR access cover and turn VOLTS control fully anti-clockwise. Start the generating set and run on no-load at nominal frequency. Slowly turn VOLTS control potentiometer clockwise until rated voltage is reached. Refer to Fig. 4a - 4d for control potentiometer location.

Important ! **Do not increase the voltage above the rated generator voltage shown on the generator nameplate.**

The STABILITY control potentiometer will have been pre-set and should normally not require adjustment, but should this be required, usually identified by oscillation of the voltmeter, refer to Fig. 4a - 4d for control potentiometer location and proceed as follows:-

1. Run the generating set on no-load and check that speed is correct and stable.

2. Turn the STABILITY control potentiometer clockwise, then turn slowly anti-clockwise until the generator voltage starts to become unstable.

The correct setting is slightly clockwise from this position (i.e. where the machine volts are stable but close to the unstable region).

Katolight Service - Master Repair Manual - Page 993

4.7 LOAD TESTING

Warning ! **During testing it may be necessary to remove covers to adjust controls exposing 'live' terminals or components. Only personnel qualified to perform electrical service should carry out testing and/or adjustments. Refit all access covers after adjustments are completed.**

4.7.1 AVR ADJUSTMENTS

Refer to Fig. 4a - 4d for control potentiometer locations.

Having adjusted VOLTS and STABILITY during the initial start-up procedure, other AVR control functions should not normally need adjustment. If instability on load is experienced recheck stability setting. Refer to subsection 4.6.

If however, poor voltage regulation on-load or voltage collapse is experienced, refer to the following paragraphs on each function to a) check that the symptoms observed do indicate adjustment is necessary, and b) to make the adjustment correctly.

4.7.1.1 UFRO (Under Frequency Roll Off) (AVR Types SX440, SX421, MX341 and MX321)

The AVR incorporates an underspeed protection circuit which gives a voltage/speed (Hz) characteristic as shown:

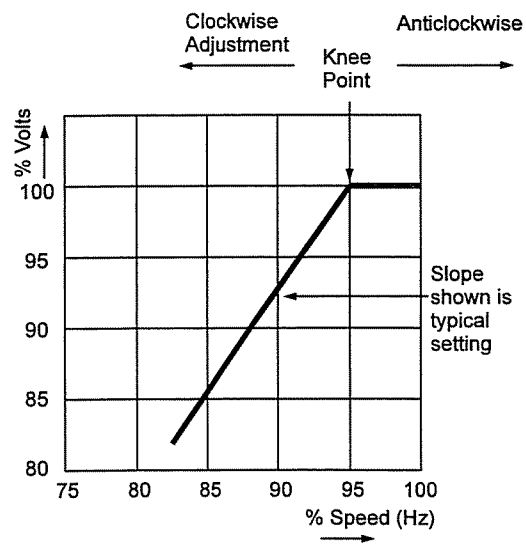

Fig. 5

The UFRO control potentiometer sets the "knee point".

Symptoms of incorrect setting are a) the light emitting diode (LED) indicator, just above the UFRO Control potentiometer, being permanently lit when the generator is on load, and b) poor voltage regulation on load, i.e. operation on the sloping part of the characteristic.

Clockwise adjustment lowers the frequency (speed) setting of the "knee point" and extinguishes the LED. For Optimum setting the LED should illuminate as the frequency falls just below nominal frequency, i.e. 47Hz on a 50Hz generator or 57Hz on a 60Hz generator.

Important ! **With AVR Types MX341 and MX321. If the LED is illuminated and no output voltage is present, refer to EXC TRIP and/or OVER/V sections below.**

4.7.1.2 EXC TRIP (Excitation Trip) AVR Types MX341 and MX321

An AVR supplied from a permanent magnet generator inherently delivers maximum excitation power on a line to line or line to neutral short circuit. In order to protect the generator windings the AVR incorporates an over excitation circuit which detects high excitation and removes it after a pre-determined time, i.e. 8-10 seconds.

Symptoms of incorrect setting are the generator output collapses on load or small overload, and the LED is permanently illuminated.

The correct setting is 70 volts +/- 5% between terminals X and XX.

4.7.1.3 OVER/V (Over Voltage) AVR Types SX421 and MX321

Over voltage protection circuitry is included in the AVR to remove generator excitation in the event of loss of AVR sensing input.

The MX321 has both internal electronic de-excitation and provision of a signal to operate an external circuit breaker.
The SX421 only provides a signal to operate an external breaker, which MUST be fitted if over voltage protection is required.
Incorrect setting would cause the generator output voltage to collapse at no-load or on removal of load, and the LED to be illuminated.

The correct setting is 300 volts +/-5% across terminals E1, E0.

Clockwise adjustment of the OVER/V control potentiometer will increase the voltage at which the circuit operates.

4.7.1.4 TRANSIENT LOAD SWITCHING ADJUSTMENTS AVR Types SX421, MX341 and MX321

The additional function controls of DIP and DWELL are provided to enable the load acceptance capability of the generating set to be optimised. The overall generating set performance depends upon the engine capability and governor response, in conjunction with the generator characteristics.

It is not possible to adjust the level of voltage dip or recovery independently from the engine performance, and there will always be a 'trade off' between frequency dip and voltage dip.

DIP-AVR Types SX421, MX341 and MX321

The dip function control potentiometer adjusts the slope of the voltage/speed (Hz) characteristic below the knee point as shown below:

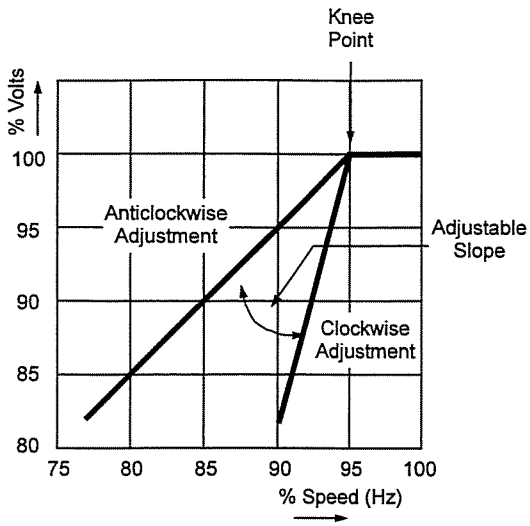

Fig. 6

DWELL-AVR Type MX321

The dwell function introduces a time delay between the recovery of voltage and recovery of speed.

The purpose of the time delay is to reduce the generator kW below the available engine kW during the recovery period, thus allowing an improved speed recovery.

Again this control is only functional below the "knee point", i.e. if the speed stays above the knee point during load switching there is no effect from the DWELL function setting.

Clockwise adjustment gives increased recovery time.

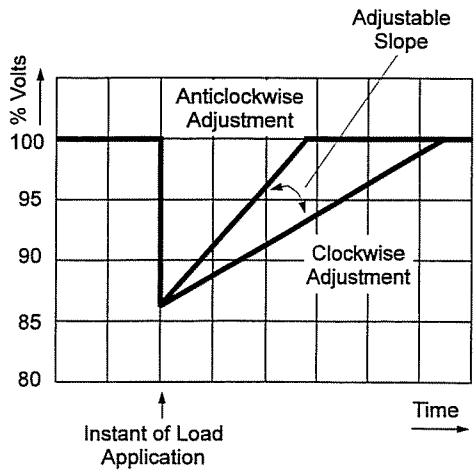

Fig. 7

The graphs shown above are representations only, since it is impossible to show the combined effects of voltage regulator and engine governor performance.

Warning !

Failure to refit covers can result in operator personal injury or death.

4.7.1.5 RAMP
AVR Type MX321

The RAMP potentiometer enables adjustment of the time taken for the generator's initial build up to normal rated voltage during each start and run up to speed. The potentiometer is factory set to give a ramp time of three seconds, which is considered to be suitable for most applications. This time can be reduced to one second by turning the pot. fully counter clockwise, and increased to eight seconds by turning the pot. fully clockwise.

4.8 ACCESSORIES

Refer to the "ACCESSORIES" Section of this Manual for setting up procedures related to generator mounted accessories.

If there are accessories for control panel mounting supplied with the generator refer to the specific accessory fitting procedures inserted inside the back cover of this book.

Replace AVR access cover after all adjustments are completed.

SECTION 5

INSTALLATION - PART 2

5.1 GENERAL

The extent of site installation will depend upon the generating set build, e.g. if the generator is installed in a canopied set with integral switchboards and circuit breaker, on site installation will be limited to connecting up the site load to the generating set output terminals. In this case reference should be made to the generating set manufacturer's instruction book and any pertinent local regulations.

If the generator has been installed on a set without switchboard or circuit breaker the following points relating to connecting up the generator should be noted.

5.2 GLANDING

The terminal box is arranged for glanding on the right hand side (or if specifically ordered on the left hand side) viewed from the non drive end. Both panels are removable for drilling/ punching to suit glands/or glanding boxes. If single core cables are taken through the terminal box side panel an insulated or non-magnetic gland plate should be fitted.

At entry to the terminal box incoming cables should be supported by a recognised glanding method such that minimum unsupported weight, and no axial force is transferred to the terminal assembly.

Incoming cables external to the terminal box should be supported at a sufficient distance from the centre line of the generating set so as to avoid a tight radius at the point of entry into the terminal box panel, and allow movement of the generator set on its anti-vibration mountings without excessive stress on the cable.

Before making final connections, test the insulation resistance of the windings. The AVR should be disconnected during this test and RTD leads grounded.

A 500V Megger or similar instrument should be used. Should the insulation resistance be less than 5MΩ the windings must be dried out as detailed in the Service and Maintenance section of this manual.

When making connections to the terminals of Frame 4 generators, the incoming cable termination lug should be placed on top of the winding lead termination lug(s) and then clamped with the nut provided.

Important ! **To avoid the possibility of swarf entering any electrical components in the terminal box, panels must be removed for drilling.**

5.3 TORQUE SETTINGS FOR TERMINAL CONNECTIONS

Pre treatment: Clean plated surfaces with a degreasing agent, then lightly abrade them to remove any tarnish. Don't score the surface.

The **generator torque settings** for all connections, links, CT's, accessories, cables, etc. is 45 Nm.

The **customer output cables** should be connected to the terminals using 8.8 grade steel bolts and associated anti-vibration hardware.

The following table is for your guidance.

FRAME	HOLE SIZE	BOLT SIZE	TORQUE Nm
4	-	12	45
5	13	12	50
6	17	14	70
7	17	16	90

Table 3

Carry out **periodic checks** to ensure the correct torque settings.

5.4 EARTHING

The neutral of the generator is not bonded to the generator frame as supplied from the factory. An earth terminal is provided inside the terminal box adjacent to the main terminals. Should it be required to operate with the neutral earthed a substantial earth conductor (normally equivalent to one half of the section of the line conductors) must be connected between the neutral and the earth terminal inside the terminal box. It is the responsibility of the generating set builder to ensure the generating set bedplate and generator frame are all bonded to the main earth terminal in the terminal box.

Caution ! **Reference to local electricity regulations or safety rules should be made to ensure correct earthing procedures have been followed.**

5.5 PROTECTION

It is the responsibility of the end user and his contractors/sub-contractors to ensure that the overall system protection meets the needs of any inspectorate, local electricity authority or safety rules, pertaining to the site location.

To enable the system designer to achieve the necessary protection and/or discrimination, fault current curves are available on request from the factory, together with generator reactance values to enable fault current calculations to be made.

Warning ! **Incorrect installation and/or protective systems can result in personal injury and/or equipment damage. Installers must be qualified to perform electrical installation work.**

5.6 COMMISSIONING

Ensure that all external cabling is correct and that all the generating set manufacturer's pre-running checks have been carried out before starting the set.

Generators fitted with air filters should have the filters charged with oil prior to commissioning. Refer to Service Section for charging procedure (subsection 7.3.2).

The generator AVR controls will have been adjusted during the generating set manufacturer's tests and should normally not require further adjustment.

Should malfunction occur during commissioning refer to Service and Maintenance section 'Fault Finding' procedure (subsection 7.4).

SECTION 6

ACCESSORIES

Generator control accessories may be fitted, as an option, in the generator terminal box. If fitted at the time of supply, the wiring diagram(s) in the back of this book shows the connections. When the options are supplied separately, fitting instructions are provided with the accessory.

The following table indicates availability of accessories with the differing AVRs.

AVR Model	Paralleling Droop or Astatic	Manual Voltage Regulator	VAr/PF Control	Current Limit
SX440	✔	×	✔	×
SX421	✔	×	✔	×
MX341	✔	✔	✔	×
MX321	✔	✔	✔	✔

Table 4

6.1 REMOTE VOLTAGE ADJUST (ALL AVR TYPES)

A remote voltage adjust (hand trimmer) can be fitted.

The remote voltage adjustment potentiometer is connected across AVR terminals 1-2.

These terminals are normally linked.

When the remote voltage adjust potentiometer is used the link across terminals 1-2 must be removed.

On AVR types SX440 and MX341 the link 1-2 is on an adjacent terminal block.

On AVR types SX421 and MX321 the link 1-2 is on the AVR terminals.

6.2 PARALLEL OPERATION

Understanding of the following notes on parallel operation is useful before attempting the fitting or setting of the droop kit accessory. When operating in parallel with other generators or the mains, it is essential that the phase sequence of the incoming generator matches that of the busbar and also that all of the following conditions are met before the circuit breaker of the incoming generator is closed on to the busbar (or operational generator).

1. Frequency must match within close limits.
2. Voltages must match within close limits.
3. Phase angle of voltages must match within close limits.

A variety of techniques, varying from simple synchronising lamps to fully automatic synchronisers, can be used to ensure these conditions are met.

Once connected in parallel a minimum instrumentation level per generator of voltmeter, ammeter, wattmeter (measuring total power per generator), and frequency meter is required in order to adjust the engine and generator controls to share kW in relation to engine ratings and kVAr in relation to generator ratings.

Important ! Failure to meet conditions 1, 2, and 3 when closing the circuit breaker, will generate excessive mechanical and electrical stresses, resulting in equipment damage.

It is important to recognise that

1. kW are derived from the engine, and speed governor characteristics determine the kW sharing between sets

and

2. kVAr are derived from the generator, and excitation control characteristics determine the kVAr sharing.

Reference should be made to the generating set manufacturer's instructions for setting the governor controls.

6.2.1 DROOP

The most commonly used method of kVAr sharing is to create a generator voltage characteristic which falls with decreasing power factor (increasing kVAr). This is achieved with a current transformer (C.T.) which provides a signal dependent on current phase angle (i.e. power factor) to the AVR.

The current transformer has a burden resistor on the AVR board, and a percentage of the burden resistor voltage is summed into the AVR circuit. Increasing droop is obtained by turning the DROOP control potentiometer clockwise.

The diagrams below indicate the effect of droop in a simple two generator system:-

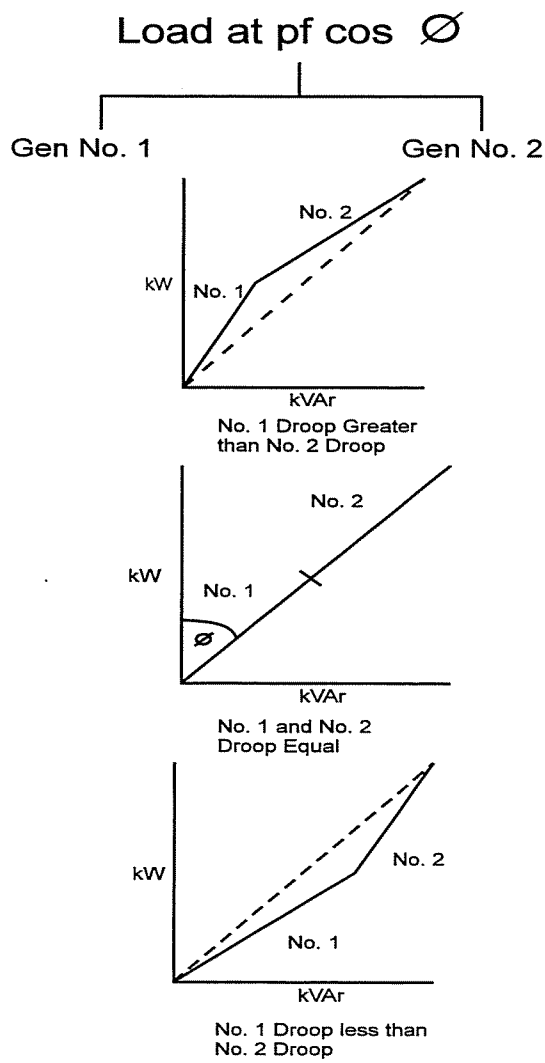

Fig. 8

Katolight Service - Master Repair Manual - Page 997

Generally 5% droop at full load current zero p.f. is sufficient to ensure kVAr sharing.

If the droop accessory has been supplied with the generator it will have been tested to ensure correct polarity and set to a nominal level of droop. The final level of droop will be set during generating set commissioning.

Although nominal droop setting may be factory set it is advisable to go through the setting procedure below.

6.2.1.1 SETTING PROCEDURE

Depending upon available load the following settings should be used - all are based on rated current level.

0.8 P.F. LOAD	(at full load current)	SET DROOP TO 3%
Zero P.F. LOAD	(at full load current)	SET DROOP TO 5%

Setting the droop with low power factor load is the most accurate.
